Relaxation and imagery techniques are often used to induce an altered state of consciousness or a hypnotic trance state. All hypnosis is self-hypnosis. A trained professional can teach a patient to enter a hypnotic trance state. It is important, clinically, to recognize and this state, because in it the individual is typically more suggestible, or more receptive to new ideas and initiation of new behaviors. According to Milton Erikson, in hypnosis the “limits of one’s usual frame of reference and beliefs are temporarily altered so that one can be receptive to other patterns of association and modes of mental functioning that are more conducive to problem solving.” Hypnosis has been shown to be helpful in the management of pain, dyspnea, anxiety, and phobias. It is contraindicated in patients with cognitive impairment.

Biofeedback

Biofeedback involves the use of devices that amplify physiological processes (e.g., blood pressure, muscle activity, skin temperature, perspiration, pulse, respiratory rate, and electroencephalography) that ordinarily cannot be perceived without amplification. Patients are guided through relaxation and imagery exercises and are instructed to alter their physiological processes using as a guide the provided biofeedback (typically visual or auditory data). The primary objective of biofeedback is to promote relaxation. It is a noninvasive procedure. It has been shown to be effective for anxiety and tension headaches.

Music Therapy

Music therapy in the palliative care setting is essential. Music can break the cyclic nature of pain, alter mood, promote relaxation, and improve communication. Music can facilitate the participation of the patient with family and hospital staff. Music therapists apply psychotherapeutic skills in the setting of music as they care for patients with advanced cancer. Music therapy interventions consist of use of precomposed songs (reflecting messages or feelings that are foremost in the patient’s thoughts), improvisation (offering opportunities for spontaneous expression and discovery), chanting and toning (use of vocalization to promote attentiveness and relaxation), imagery (exploration of images and feelings that arise in the music), music listening techniques (which facilitate reminiscence and build self-esteem through reflection on accomplishments), and taping of the music session as a gift for the family. Music therapy may help to facilitate a life review for the patient. It can also help in management of the most common symptoms of advanced cancer: pain, anxiety and depression, nausea and vomiting, shortness of breath, and sleeplessness. Live music has been shown to be more effective than taped music.

Art Therapy

Art therapy is a form of psychotherapy. Art therapists are trained professionals. Art therapy focuses on assisting patients to express, explore, and transform sensations, emotions, and thoughts connected with physical and psychological suffering. In art therapy, the art therapist and the art materials (e.g., paper, colored markers, oil pastels, cut-up images from magazines) help patients get in touch with their feelings, their fears, and their hopes and put them out onto the paper, thus helping patients process their experience of illness. It can easily be accommodated to hospitalized inpatients as well as to outpatient art groups or individuals. Art therapy can assist patients with advanced-stage cancer in the management of pain, fatigue, and stress. Art images can serve to help the dying patient with issues of anger, bereavement, and loss. The art therapist may help dying patients find “personal symbols” to express something so powerful and so mysterious as the end of life.

Biologically Based Therapies

Alternative diets have an ancient history, both medical and cultural, of plants and herbs as the first medicines. The example
of vitamin C curing scurvy reinforces the idea of foods being medicines and curing illness. Some of the ancient medicine systems are still being practiced today; for example, Ayurvedic medicine uses special diets, herbs, and cleansings to treat illness and promote health.

Today’s food pyramid recommends fiber, grains, fruits and vegetables, and less protein, meat, and dairy products than was emphasized in earlier U.S. Department of Agriculture government guidelines. It emphasizes balance. Changes in guidelines are based on carefully controlled scientific studies. Many alternative and fad diets, herbs, and supplements are either not scientifically validated or are marketed despite having been found worthless or harmful.

**Nutrition**

Some alternative practitioners believe that dietary treatments can prevent cancer or even go a step further to believe that foods or vitamins can cure cancer. The American Cancer Society Guidelines on Nutrition form the basis for a healthful diet that emphasizes vegetables, fruits, legumes, and whole grains; low-fat or nonfat dairy products; and limited amounts of red meat (lean preferred). Special dietary problems should be discussed with the doctor and an oncology registered dietitian. It should be emphasized to the patient and family that the doctor should be informed before the patient takes any vitamin, mineral, or herb.

**Special Diets**

**Macrobiotics.** The philosophy of the microbiotic diet is curing through diet. It was developed in the 1930s by a Japanese philosopher, George Ohsawa. Originally, the diet consisted of brown rice with very little liquid. It was nutritionally deficient. Today it consists of 50% to 60% whole grains, 25% to 30% vegetables, and the remainder beans, seaweeds, and soups. Soybean foods are encouraged, and a small amount of fish is allowed. In-season foods are preferred. Proponents of this diet believe that it cures cancer. There is no evidence that the macrobiotic diet is beneficial for cancer patients.

**Megavitamin and Orthomolecular Therapy.** Some alternative practitioners believe that huge doses of vitamins can cure cancer. Linus Pauling coined the term orthomolecular, meaning large quantities of minerals and other nutrients. His claim that large doses of vitamin C could cure cancer was disproved. There was no evidence in 1979 that megavitamin or orthomolecular therapy was effective in treating any disease. In 1985, Moertel and colleagues showed that vitamin C was ineffective against advanced malignant cancer. There are side effects to the overdosing of vitamins and minerals. A nutritionally healthy diet is recommended for overall good health. Some people have special needs and may require supplements. Patients should not attempt to treat themselves with megadoses of vitamins or minerals, but should seek professional attention for nutritional advice.

**Metabolic Therapies.** Metabolic therapies are based on the theory that disease is caused by the accumulations of toxic substances in the body. The goal of treatment is to eliminate the toxins. Metabolic therapies usually include a special diet; high-dose vitamins, minerals, or other dietary supplements; and detoxification with coffee enemas or irrigation of the colon. Colon detoxification is not used in mainstream medicine, and there are no data to support the claims that dried food and toxins remain stuck in the walls of the colon. The development of metabolic therapy is attributed to Max Gerson, a physician who emigrated from Germany in 1936. Today, cancer is the most common illness treated with metabolic therapies. Research does not substantiate the beliefs and practices of metabolic therapies, and patients may lose valuable time during which they could be receiving treatments with proven benefits.

**Individual Biological Therapy.** Advocates of shark and bovine cartilage therapy claim that it can reduce tumor size, slow or stop the growth of cancer, and help reverse bone diseases such as osteoporosis. More importantly, shark and bovine cartilage are thought to play a role in angiogenesis, which involves halting the blood supply to cancer cells. There is no firm evidence that cartilage treatment is effective against cancer.

**Herbal Medicine**

Herbs have been used as medicines going back to ancient times. Belief in the magic of herbs for the treatment of cancer exists today, especially in the face of advanced cancer and few or no options. There is a romance about herbs in that they are natural and come from the earth and therefore must be pure, safe, and harmless. A major concern exists that patients are using herbs indiscriminately on a routine basis without knowledge that they interact with drugs, can interfere with the efficacy of anticancer drugs, and can cause death. There is a lack of knowledge that most herbal remedies have not been tested in carefully designed clinical studies. Currently, some herbal remedies are being studied for their ability to induce or extend a cancer remission. We must remember and teach our patients that herbs have potency comparable to that of pharmaceuticals. They can cause medical problems such as allergic reactions, toxic reactions, adverse effects, drug interactions, and drug contamination.

An important aspect of cancer care is to recognize that herbs can be toxic to cancer patients and should be discussed with the doctor and other qualified practitioners. MSKCC advises patients to avoid taking any herbs for 2 weeks before any cancer therapy and to refrain from using supplements while in the hospital. Some herbs, such as St. John’s wort, may interfere with the effectiveness of chemotherapy. Garlic may alter clotting times in a surgical candidate. Dong qui may make the skin more sensitive to burns during radiation. The active ingredients in many herbs are not known. In the United States, herbal and other dietary supplements are not regulated by the U.S. Food and Drug Administration (FDA) as drugs.
This means that they do not have to meet the same standards as drugs and over-the-counter medications for proof of safety and effectiveness. Identifying the active ingredients and understanding how they affect the body are important areas of research being done by NCCAM. Differences have been found in some cases between what is listed on the label and what is in the bottle, and some contaminants have been identified as heavy metals, microorganisms, or unspecified prescription drugs and adulterants. Standardization and authentication of herbs is important. An excellent resource to obtain information about herbs can be found on MSKCC’s website for Integrative Medicine and in a resource book on herb-drug interactions. The website has a consumer version as well as a professional version; both are available to all at no cost. Neither the author, the hospital, nor the publisher makes any medical recommendations about herbs; the website is specifically for information.

Mikail and colleagues found in a study of medical residents that they had a knowledge deficit concerning herbal medicines. Ninety percent of them wanted to learn more about herbal medicine, including uses of herbs, contraindications, and drug interactions, as well as talking to patients about their use. As the prevalence of herbal remedy use grows, equipping nurses and doctors with information and vocabulary will help them discuss with and offer their patients proper precautions. Patients should be encouraged to talk to their doctors and nurses about the herbs they are taking. It is important to listen with patience, and then to respond without judgment. This approach promotes open, ongoing communication between the patient and the doctor and nurse.

Manipulative and Body-Based Methods

Touch is the first sense to develop, and it is the primary way of experiencing the world, starting with infancy up until the moment of our last breath. It is critical to growth and development. Infants, the elderly, the ill, and animals that do not receive regular touch fail to thrive and eventually die. In ancient times, the “laying on of hands” was the early practice of healing by touch. Medicine consisted of touch before the advent of pharmaceutical therapies. Today drugs, technology, paperwork, and heavy patient loads may keep the doctor and nurse from the bedside. Patients comment, “I don’t get touched very much anymore. If I do it is a medical touch, and it can hurt. My family and friends don’t seem to touch either, maybe out of fear.” Touch is a healing agent, but is underutilized by healing practitioners. Touch is our most social sense and implies a communication between two people. Cultural differences in touching are essential to keep in mind so as to always be respectful.

Massage

Massage therapy is one of the oldest health care practices in use. Chinese medical texts referred to it more than 4000 years ago. It is one of the most widely accepted forms of complementary therapies today. Massage employs the manual techniques of rubbing, stroking, tapping, or kneading the body’s soft tissues to influence the whole person. Simms suggested that touch is a fundamental element in patient care that can encourage better communication and promote comfort and well-being. The concern of the medical profession and patients has been that massage would spread cancer cells. There is no evidence that this is the case, because the stimulation caused by massage is no more than everyday exercise. The benefits of massage are many and include improving circulation, relaxing muscles and nerve tissue, releasing tension, reducing pain, decreasing anxiety and depression, energizing, and promoting an overall sense of well-being. Massage is contraindicated under some circumstances: over metastatic bones (for risk of bone fracture or breakage), if the platelet count is less than 35,000 to 40,000/mm³ (for risk of bruising), over sites of blood clots (for risk of promoting movement of a thrombus in the circulation), and over surgical sites or rashes. Medical massage for the cancer patient, and especially for the end-stage cancer patient, uses light pressure. Deep tissue massage is not appropriate and is potentially harmful.

Aromatherapy

Aromatherapy is the controlled use of plant essences for therapeutic purposes. Essential oils are the aromatic essences of plants in the form of oil or resin, which has been extracted in a highly concentrated solution. The history of medicinal use of plant oils goes back to ancient Egypt, China, and Renaissance Europe. Essential oils are thought to have different mechanisms of action: antiviral, antiseptic, antibacterial, anti-inflammatory, fungicidal, sedative, and easing congestion. Aromatherapy is often practiced with massage and has been found to destress, empower, and promote communication and a sense of security. Aromatherapy is a delightful tool in enhancing yoga. Aromatherapy should be administered only by a certified practitioner. Essential oils should not be administered orally or applied undiluted to the skin. Possible contraindications to the use of essential oils are contagious disease, venous thrombosis, open wounds, and recent surgery. Possible adverse events are photosensitivity, allergic reactions, nausea, and headache. Many essential oils have the potential to enhance or reduce the effects of prescribed medications.

Reflexology

Reflexology is touch therapy that goes back 5000 years to ancient Egypt. It is based on the assumption that the body contains energy flowing through it. Reflexology is an art and a science that is based on the principle that there are reflex points and areas in the ears, hands, and feet that correspond to every gland, organ, and part of the body. By skillful stimulation of these areas and points with hand, finger, and thumb techniques, the body systems are facilitated to greater balance. Reflexology should be done to the tolerance of the patient; it should not hurt. Reflexology is generally used to reduce stress, to promote relaxation and sleep, to improve
circulation, to energize, to diminish symptoms of pain, anxiety, nausea, and peripheral neuropathy, and to promote an overall sense of well-being. It can be made special and pleasant when preceded by an aroma foot bath. It is contraindicated if blood clots, infection, skin rash, bruising, or wounds are present on the extremities. Reflexology can be performed anywhere, requires no special equipment, is noninvasive, and does not interfere with the patient’s privacy. It can easily be taught to the family to empower them to provide comfort to their loved one.

**Acupressure**

Acupressure is the pressing of a single point or specific acupuncture point to relieve pain and stress in a particular area or part of the body. It is acupuncture without the needles. It involves placing the finger firmly on an acupoint. More than 300 acupoints dot the lengths of the hypothesized meridians (channels) that run vertically head to toe. The acupoint to be pressed is determined by the energy channel that is blocked and is causing the problem. Acupressure promotes relaxation and comfort. It should be done to the tolerance of the patient. It need not be painful. It should not be applied near areas of fractures or broken bones, or near blood clots, wounds, sores, or bruises.

**Shiatsu**

Shiatsu is a modern outgrowth of ancient acupressure. It is a Japanese body therapy that works on the energetic pathways (meridians) and points of access to acupuncture points in order to harmonize the energy flow (qi). The philosophy is rooted in TCM, which views illness as being caused by energy imbalances. Shiatsu, a touch therapy, was developed from an ancient form of Japanese massage into the use of pressure with thumbs, palms, elbows, and knees and stretching, applied to these meridians and to the specific acupoints that are located on these pathways. The focus is on prevention and healing. Shiatsu is contraindicated with widespread bone metastases, pulmonary emboli, and deep vein thromboses. The benefits are relaxation, higher energy levels, improved physical capability, and enhanced symptom control. Light touch is suggested for the palliative care patient.

**Polarity**

Polarity views good health as a balance among internal energies, such as earth, air, fire, water, and space. When these energies are blocked due to stress or other factors, physical and emotional problems follow. The therapist provides a series of gentle stretching, light rocking, and holding of pressure points until the body’s energy is brought into balance. Most often patients report a deep sense of relaxation.

**Chiropractic**

The hands-on joint manipulation known as chiropractic is particularly helpful for lower back pain. Chiropractic medicine is a system of therapy based on the premise that the relationship between structure (primarily the spine) and function (as coordinated by the nervous system) in the human body is a significant health factor. Disease is considered to be the result of irregular or misaligned vertebrae and abnormal functioning of the nervous system. Back pain is one of the most frequent health problems, although neck, shoulder, head, and carpal tunnel syndrome are frequently treated by chiropractors. The normal transmission and expression of nerve energy are essential to the restoration and maintenance of health. Chiropractic medicine emphasizes the inherent recuperative power of the body to heal itself without the use of drugs or surgery. The method of treatment usually involves manipulation of the spinal column and other body structures to realign or realign joints. Research evidence does not support chiropractic claims that cancer can be cured with spinal manipulation. Chiropractic is not recommended for patients with advanced cancer.

**Yoga**

Yoga is the Sanskrit word for union or oneness. It is a centuries-old Eastern philosophy, science, and art form that can be used as a tool to achieve inner peace and freedom. Through mental (meditation) and physical (movement and simple poses with deep breathing) techniques, pathways lead into the yoga state of oneness. Yoga helps align the body, promotes relaxation, and reduces fatigue. There are different types of yoga: hatha yoga (physical posturing), pranayama (yoga breathing), mantra yoga (sacred sound symbols in the sound of a chant designed to awaken the left hemisphere of the brain to rational thinking and clarity), and yantra yoga (visualizing symbols and energy patterns). Yoga can be accommodated to any patient, in any position, at any stage of their cancer. It should be guided by an accredited yoga teacher and done to the tolerance of the patient, starting out very slowly and simply.

**Exercise**

Patients with cancer often experience lack of energy and loss of physical performance and strength. Researchers have found that exercise can alleviate patients’ fatigue and improve their physical performance and psychological outlook. A pilot study demonstrated that myeloma patients with bone lesions were able to do a home-based exercise program, once taught, without supervision and without injury. Another pilot study supported the suitability of exercise for the palliative care population who were given an exercise program, which included 5-minute walks, arm exercises with a resisted rubber band in a chair, marching on a spot, or dancing to their favorite music. All patients expressed a sense of satisfaction in attaining their activity levels. Individuals who knowingly and actively participate in their care have a more positive outlook than those who are passive participants. Patients with advanced cancer should be assessed first by a medical professional and then
given an individualized exercise program that they can gradually work into.

Energy Therapies

NCCAM has classified Reiki, Qi gong, and Therapeutic Touch (TT) as biofield therapies. Biofield therapies are defined as those therapies intended to affect energies that purportedly surround and interpenetrate the human body. They are thought to be able to rebalance the biofield. Some believe that these therapies can remove the subtle causes of illness and enhance overall resilience. The existence of such fields has not yet been scientifically proven.

Reiki

Reiki is a vibrational or subtle energy most commonly facilitated by light touch. Rei means universal or highest energy, and ki means subtle energy. Reiki therapy is thought to balance the biofield and to strengthen the body to heal itself. Reiki is offered to a fully clothed individual and involves placement of hands on the head and front and back; it may include placement of hands on the site of discomfort, if desired. The gentle touch is soothing to patients and promotes deep relaxation.

Qi gong

Qi gong is a component of traditional Chinese medicine that combines movement, meditation, and regulation of breathing to enhance the flow of qi (vital energy) in the body, to improve circulation, and to enhance immune function. With practice, qi gong can lower stress levels, reduce anxiety, and provide an increased well-being and peace of mind. It is important to note that there is no evidence that qi gong exercises can increase resistance to illness or cure existing disease.

Therapeutic Touch

TT, as described by Dolores Krieger, is “the conscious, intentional act of directing universal energy with the intent to help and heal.” It is defined by Nurse Healers Professional Associates as an intentionally directed process of energy exchange during which the practitioner uses the hands as a focus to facilitate the healing process. TT was developed by Kreiger and Dora Kunz in the 1970s from studying techniques of ancient healing practices. It is believed that healing is promoted when the body’s energies are in balance. The hands are usually passed over the patient so that the practitioner can detect energy imbalances and facilitate rebalancing. It is believed to affect a profound relaxation response and to help with pain. The effectiveness of TT was evaluated in a meta-analytic review. The results seemed to indicate that TT has a positive and medium effect on physiological and psychological variables, although the studies had significant methodological issues. More research needs to be done. Until then, TT is safe to use and seems to provide comfort to patients, even without scientific evidence.

Pre-therapy Nursing Assessment

The nurse needs to assess the patient first, before any therapy is given or ordered.

Current Medical History

The practitioner should determine the diagnosis, extent of disease, location of tumors, sites of metastatic disease, medications, CAM therapies (including vitamins, supplements, and herbs), site of blood clots, surgical site, site of radiation, and blood counts. He or she should determine which positions are most comfortable for the patient. All information must be obtained from the chart, doctor, or patient before doing a touch therapy.

Remember:
- Do not massage on bones where there is metastatic disease, because bones are at risk for fracture or breakage; if the platelet count is <35,000 to 40,000/mm$^3$ because there is risk for bruising; on a site of current radiation, due to increased fragility of the skin; or where there are blood clots, due to the risk of setting a clot free to travel.
- There is no deep tissue massage given especially in a patient with advanced disease. Gentle light massage is most appropriate.

Symptoms

Ask patients what symptoms they are currently experiencing. Ask patients to rate their symptoms on a scale of 0 to 10 as an estimate of their level of distress. This is necessary to select the most appropriate and the most effective CAM therapy. If the patient has pain, medicate first, before therapy is provided; the patient is much more likely to enjoy it. Have patients rate their individual symptoms after the chosen therapy, to make clear to the patient and medical staff the benefit of the therapy.

Religious/Cultural Background

What culture is the patient from? What therapies were used at home? Are there any cultural taboos? For example, it is not acceptable for a Hasidic Jewish man to be touched by a woman.

Previous Use

What do the patients know about these therapies? Have they had previous experiences? Were they positive or negative experiences? Do they have any fears or reticence?
Patient’s Requests

Who is asking for these therapies? Is it the patient or the family? What would the patient like to try?

Symptom Management with Evidence-Based Complementary Therapies

Dying patients experience a heavy symptom burden, including pain, nausea and vomiting, anxiety, depression, fatigue, dyspnea, insomnia, and peripheral neuropathy. When some of these symptoms are treated with medicines such as opioids, additional problematic side effects, such as sedation, delirium, and constipation, can occur. Complementary therapies have fewer, if any, side effects and may be more consistent to the patient’s and family’s culture and health care beliefs.68

Complementary Therapies for Control of Pain

A multicenter trial of seriously ill hospitalized patients with diverse diagnoses documented that 50% of patients who died in the hospital had moderate to severe pain during the last few days before death.69 Pain is highly prevalent for the patient with advanced-stage cancer. Cancer pain can be very difficult to control; analgesic drugs do not always completely relieve it. Pain can isolate the patient from everything and everyone as it completely takes over, preventing communication between the patient and family. It can prevent a peaceful good-bye. The following adjuvant complementary therapies can provide much-needed extra help for pain control: acupuncture, massage, reflexology, hypnosis, music, Reiki, and art therapy. They can be chosen based on the nurse’s assessment and the patient’s wishes.

Control of pain is the best known use of acupuncture. Randomized trials support the use of acupuncture for acute pain, in dental surgery,70 and for chronic pain such as migraine headaches.71 In one study, pain control was achieved for at least 1 month in all of the patients with mild to moderate pain and in 72% of those with severe pain72; 48% of the patients in another study reported pain relief for 3 days and an increase in mobility.73 Auricular acupuncture has demonstrated analgesic effects for cancer pain.74 One very interesting study with pediatric patients, ages 6 to 18 years, successfully used acupuncture and hypnosis for chronic pain.75 Acupuncture was also easily integrated into an outpatient clinic, where it provided 71% relief of pain.76

Massage therapy and aromatherapy provide pain relief and a sense of well-being in cancer patients experiencing pain.77–80 Ferrell-Torry and Glick81 reported that massage reduced pain perception by an average of 60%. Of note is a study by Walach and colleagues,81 which found that pain improvement lasted until the 3-month follow-up visit. NCCAM recommends massage for treatment of refractory cancer pain. Reflexology has a significant effect on the symptom of pain.79,82,83 It is a relatively simple nursing intervention and can be quite effective in <10 minutes. Relaxation and imagery can provide some pain relief.84,85 Marcus and associates86 suggested numbing parts of the body where there is pain through the use of hypnosis. These therapies require that the patient be alert and not in too much pain to concentrate.

In palliative care, music therapists provide services to treat pain.80 Music increases the patient’s comfort, is soothing, and creates a safe environment to ease the dying process. Reiki, which is safe and noninvasive, facilitates relaxation and decreases pain. Hartford Hospital, which has a hospital Reiki program, reports that Reiki provides significant pain relief for surgery patients.87 Reiki, because it is a light holding touch, can be given to any patient. MSKCC uses art therapy to help patients communicate the painful side of their illness in such a way that they can feel understood and respected.88 This intervention, with the guidance of a trained art therapist, uses a “body outline” that allows the patient to draw the location and type of physical pain and express the feelings around it without guilt or shame. This may be the starting point for some patients who seem to be verbally unreachable and might benefit from communicating their physical and emotional pain with the result of lessening the distress.

Complementary Therapies for Control of Nausea and Vomiting

Nausea and vomiting can greatly compromise patients’ quality of life. The causes may be multiple, including a reaction to medications (chemotherapy, antibiotics, opiates), bad taste in the mouth, or bowel obstruction. Nausea and vomiting can be so severe that patients would rather discontinue their chemotherapy, or wish to die. Acupuncture, relaxation techniques, acupressure, reflexology, massage, music, imagery art therapy and meditation are effective therapies for nausea and vomiting.

Acupuncture can be used along with antiemetics. There is clear evidence that needle acupuncture is efficacious for adult postoperative and chemotherapy-related nausea and vomiting.88 There is often an element of anxiety with nausea and vomiting. Progressive muscle relaxation has been shown to be very effective in decreasing nausea and vomiting as well as anxiety.89 In a small pilot study, finger acupressure decreased nausea in women undergoing chemotherapy for breast cancer.90 They were taught to apply pressure to the anterior surface of the forearm (P6) and the back of the knee (ST36), an intervention that is easy to learn and use. Reflexology was effective in promoting relaxation, which improved nausea.91 Music therapy distracts patients by having them pick their own music, listen to live music, sing, or play an instrument, resulting in decreased nausea.92 Music therapy is easy to implement. Guided imagery encourages patients to focus on past pleasant images to distract from the negative experience of nausea.93,94 Art therapy can be used as a distraction intervention to reduce
nearly and vomiting. Meditation can also distract from the unpleasant sensation of nausea.

Complementary Therapies for Control of Anxiety

People with advanced stages of cancer may live with chronic anxiety and pain. The most common causes of anxiety in cancer patients with advanced disease are situational anxiety, previous history of anxiety, poorly controlled pain, abnormal metabolic states (e.g., hypoxia, sepsis, delirium), and side effects of medications (e.g., corticosteroids, neuroleptics). The complementary therapies that are effective for the control of anxiety are massage, reflexology, meditation, relaxation, guided imagery, Reiki, music therapy, and exercise.

Massage promoted relaxation and significantly reduced the perception of pain and anxiety. Meek reported that her hospice patients, who were in the terminal stage of illness, received a slow stroke back massage and were provided comfort and induced relaxation. Cassileth and Vickers have demonstrated a 52.2% reduction in anxiety with massage. In bone marrow transplant patients, the strongest effects were seen immediately after massage, with a reduction in diastolic blood pressure, anxiety, and nausea. A significant reduction in anxiety was seen 3 months after massage by Walach and colleagues. Family members can be taught to provide slow massage strokes to soothe the patient. Reflexology reduced anxiety in a randomized trial of patients with breast or lung cancer. Gamble and associates found that hospice patients reported 91% relief from tension and anxiety after a course of six reflexology sessions.

“Many dying patients find that the calmness and silence of meditation bring profound feelings of acceptance, well-being and inner peace.” Cancer patients frequently experience anxiety as they anticipate entering the final stages of life. Hypnotic relaxation has been found to significantly reduce terminal anxiety. Relaxation training reduced treatment-related anxiety. Imagery work can be a distraction that removes the patient from the stressor of the present. Reiki, which is a light touch therapy, promotes stress reduction and relaxation. Music therapy reduced mood disturbance in cancer patients during hospitalization for autologous bone marrow transplantation. Live music was found to be more effective than taped recorded music. Music therapy was found to be more effective in decreasing anxiety in ventilator-dependent patients than quiet time. Exercise is an intervention that may assist in the reduction of anxiety.

Complementary Therapies for Control of Depression

The National Comprehensive Cancer Network (NCCN) in their guidelines of 2003, chose to focus on the patient's distress management. They recognized that distress extends along a continuum, ranging from feelings of vulnerability, sadness, and fear to disabling conditions such as clinical depression, anxiety, panic, isolation, and existential or spiritual crisis.

An estimated 20% to 25% of cancer patients experience depression at some time during their illness. In the advanced stages of cancer, the incidence of major depressive syndromes increases to 58%. Factors that place patients at greater risk for depression are history of depression, advanced stage of cancer, poorly controlled pain, and medications. The following complementary therapies are effective for the relief of depression: mind–body therapies, massage, and music.

Depression was significantly reduced with the use of progressive muscle relaxation together with guided imagery in patients with advanced cancer. MBSR was effective in reducing anxiety and depression in cancer outpatients. Massage therapy achieved major reduction in pain, fatigue, nausea, anxiety, and depression at a major cancer center. Music therapy reduced mood disturbance in patients hospitalized for autologous stem cell transplantation. “Music therapy is an invaluable resource for diminishing suffering in advanced cancer”; and can help the patient link to inner strengths, restore a sense of identity, and open doorways during times of pain and loss. Music can help the patient begin a life review and facilitate finding meaning and purpose in life.

Complementary Therapies for Control of Fatigue

Fatigue is a common symptom among patients with advanced cancer. A multivariate analysis found that fatigue severity in advanced cancer was significantly associated with pain and dyspnea. Portenoy and Itti reported that fatigue can profoundly undermine the quality of life of patients with cancer. There are some nonpharmacological interventions for cancer-related fatigue. The following complementary therapies are recommended for cancer-related fatigue: acupuncture, exercise, massage, reflexology, mind–body therapies, and music.

MSKCC reported a 31.1% reduction in fatigue with acupuncture in a population of cancer patients with postchemotherapy fatigue. Decreased physical activity, regardless of the reason, leads to decreased energetic capacity. A pilot study provided an exercise program for advanced cancer patients, resulting in increased energy and decreased fatigue. There is a Chair Aerobics exercise class in the Integrative Medicine department at MSKCC that is run by an oncology clinical nurse specialist and personal trainer. This class is a fitness program targeted to help breathlessness and fatigue and to improve physical and psychological well-being of cancer patients. There are currently several stage IV patients in this class, who report that it is hard to get to class because of fatigue, but that after class they feel energized and proud to have accomplished something. Nail summarized a number of nonpharmacological interventions for fatigue, including aerobic exercises and attention-restoring exercises. Coleman and colleagues suggested tailoring exercise to the patients’ capabilities as they move through the disease continuum, so that they do not get discouraged. Massage and reflexology can be very stimulating as well as relaxing. Imagery can include visualization of oneself as being very active. Patients can be
very stimulated by listening to energetic music or by playing an instrument, especially the drums.

**Complementary Therapies for Control of Dyspnea**

Breathlessness is an extremely distressing and frightening symptom that can completely dominate a patient’s life. It can cause physical disability, high anxiety, dependence, and loss of self-esteem. The following complementary therapies are recommended for dyspnea: relaxation techniques, Reiki, reflexology, gentle massage, music, specific exercise, acupuncture, and hypnosis.

Lung cancer patients using breathing retraining, simple relaxation techniques, activity pacing, and psychosocial support were able to reduce breathlessness from 73% to 27%.

Reiki has been shown to reduce anxiety, as have reflexology, gentle massage, and music. Reduction of anxiety aids in the reduction of perceived breathlessness. Chair aerobics exercise helps decrease breathlessness, control panic, and improve muscle tone. Acupuncture was shown to promote quality of life in patients with chronic obstructive asthma. For patients with active, progressive, or far advanced disease, and for those with a short life expectancy, hypnosis can provide reduction of dyspnea and enhance coping.

**Complementary Therapies for Control of Insomnia**

Insomnia is a prevalent problem in cancer. Studies conducted among heterogeneous samples of cancer patients suggest that between 30% and 50% of cancer patients have sleep difficulties. The contributing factors, especially for advanced cancer, are hypoxia, pain, anxiety, delirium, medications, or withdrawal from medications. The causes need to be treated, but, in addition, therapies that promote stress reduction and relaxation can be considered. The following complementary therapies can be helpful in the management of insomnia: mind–body therapies (relaxation and imagery), massage, reflexology, Reiki, exercise, and music.

Mind–body therapies such as relaxation, imagery, meditation, and biofeedback may be chosen to reduce body tension and anxiety and promote sleep. Massage, reflexology, and Reiki, being touch therapies, can promote relaxation. Exercise is an intervention that can help reduce anxiety and improve quality of life in cancer patients. Music can promote relaxation for sleep.

**Complementary Therapies for Control of Peripheral Neuropathy**

Peripheral neuropathy is a common problem for cancer patients receiving certain chemotherapies and for those with diabetes. It is a difficult problem to treat, and its severity and recovery can vary with each patient. It can be so severe that the oncologist may have to stop the chemotherapy. It may be described by patients as numbness, tingling, or burning. Cisplatin is known to induce sensory peripheral neuropathy, and paclitaxel causes sensory and motor neuropathy. Neurological toxicity eventually decreases the patient’s ability to perform physical functions necessary for activities of daily living and thus can interfere with quality of life.

One study looked at the prevalence and patterns of use of CAM therapies in a group of outpatients with peripheral neuropathy. Reportedly, 43% of the patients used CAM for peripheral neuropathy. The following complementary therapies can be helpful in the management of peripheral neuropathy: reflexology and acupuncture.

**Support for the Family**

Caregivers of patients with cancer experience stress. They must learn to participate in complicated medical regimens, assist patients in daily activities of living, drive or accompany them to clinics or treatments, and perhaps at the same time be responsible for finances, running of the household, and preparing for the death. Perception of discomfort in the dying patient may be another stress factor for the relatives. Family members have difficulty dealing with patients’ pain, dyspnea, appetite loss, and delirium. Caregivers of cancer patients undergoing autologous hematopoietic stem cell transplantation were enrolled in a study to receive massage therapy. Massage significantly reduced anxiety, depression, and fatigue; it reduced motivation fatigue and emotional fatigue.

A program of care for family members is offered at MSKCC. Family members are offered massage, reflexology, meditation, yoga, and other evidence-based complementary therapies for stress reduction. “Touch Therapy for the Caregiver” is a monthly program offered to family members, who are taught how to give light upper back and neck massage to provide comfort to the patient. They are instructed to check with the patient’s doctor to determine where it will be safe to do gentle massage.

**Complementary and Alternative Therapies for the Nurse**

Stress and burnout in oncology is well documented. Stress and burnout are particularly relevant in oncology nursing, where nurses work closely with patients and families and bear witness to suffering and dying on a daily basis.

MSKCC’s Integrative Medicine Service offers massage to the nursing staff as well as reflexology, meditation, and yoga classes to provide a program of care for nurses. MSKCC is invested in their nurses and knows the great benefit these therapies can offer them. Programs are offered in which nurses are taught Reiki, as well as very simplified versions of gentle upper body massage and reflexology, which they can integrate into their nursing practice after reviewing the indications and contraindications. These skills are a necessary part of any palliative care program.
Summary

It is a privilege to work with cancer patients, but especially to care for those approaching their last days of life. Gone are the days when a patient or a family might be told, “There is nothing more we can do.” There remain many treatment options, including complementary therapies, that patients can choose and receive as a part of palliative care.

Nurses can educate patients and families about the safe choices of evidence-based complementary therapies that can affect their quality of life. But first, they need to educate themselves about CAM:—what these therapies are, what are their specific benefits and risks, and which ones are safe—before guiding patients. Nurses want to be respectful of the patient’s desire to seek out CAM in the setting of advanced disease. Nurses must listen to the patient and then give suggestions of effective complementary therapies for comfort. Palliative care nurses are exposed to an abnormal amount of suffering and death and need to take care of themselves in order to give to others. Use of complementary therapies for themselves will benefit all.

Nurses can help patients live their lives to the last with hope. One patient said, “I didn’t mind returning to the hospital, because I knew Integrative Medicine would be there for me.” Another inpatient reported, after her reflexology session, “You have made me want to stay alive longer, I feel so good.” And yes, there is Mary, our case history, who always looked for us in her hospital doorway and called us her angels. We cannot change the course of patients’ terminal illnesses, but we can accompany them on the last days of their journey with gentle touch.

III
Psychosocial Support
Hope has long been recognized as fundamental to the human experience. Many authors have contemplated hope, extolling it as a virtue and an energy that brings life and joy. Fromm called hope “a psychic commitment to life and growth.” Some authors assert that life without hope is impossible. Despite its positive connotations, hope is intimately bound with loss and suffering. As the French philosopher Gabriel Marcel observed, “Hope is situated within the framework of the trial.” It is this paradox that manifests itself so fully at the end of life.

Indeed, the critical role that hope plays in human life takes on special meaning as death nears. The ability to hope often is challenged, and it can elude patients and families during terminal illness. Hope for a cure is almost certainly destroyed, and even a prolonged reprieve from death is unlikely. Many patients and families experience multiple losses as they continue an illness trajectory that is marked by increasing disability and pain. Even when hope appears to be strong within the dying person or the family, it can be problematic if hopefulness is perceived to be based on unrealistic ideas about the future. Tension grows within relationships as people become absorbed in a struggle between competing versions of reality. Important issues may be left unresolved as individuals continue to deny the reality of impending death.

Despite these somber realities and the inevitable suffering, many people do maintain hope as they die, and families recover and find hope even within the experience of loss. How can this be? Part of the reason lies in the nature of hope itself—its resiliency and capacity to coexist with suffering. As witnesses to suffering and hope, palliative care nurses must understand these complexities and be confident and sensitive in their efforts to address hope and hopelessness in the people for whom they care.

---

**Key Points**

- Hope is a key factor in coping with and finding meaning in the experience of life-threatening illness.
- People facing life-threatening illness and their families do not invariably lose hope; in fact, hope can increase at the end of life.
- Nurses can implement evidence-based practices to foster and sustain hope for patients and families at the end of life.
- Nurses need to understand and respect individual variations in hope processes to provide sensitive, effective care to patients and their families at the end of life.

The Meaning of Hope in the Dying

I have these three gremlins in my head. One of them is on one side saying, “Jack, you’re going to lick this—don’t worry.” Another gremlin is on the other side saying, “Jack, you dope, you know you aren’t going to make it.” And on the middle of this is this third little guy who has to make sense of both of them and help me to keep going on with my life day after day. Sometimes, they get so loud I can’t think, but most of the time I keep them locked up, and when I’m busy they don’t bother me.

—37-year-old-man with malignant melanoma

Every time life asks us to give up a desire, to change our direction or redefine our goals; every time we lose a friend, break a relationship, or start a new plan, we are invited to widen our perspectives and to touch, under the superficial waves of our daily lives, the deeper currents of hope.

—Henri Nouwen

To assist palliative care nurses, this chapter explores the many dimensions of hope and identifies its possible influence on health and quality of life. Nursing assessment and strategies to foster hope are described. In addition, specific issues such as “unrealistic hopefulness” and cultural considerations in the expression and maintenance of hope are discussed. The goals of the chapter are to provide the reader with an understanding about this complex but vital phenomenon; to offer guidance in the clinical application of this concept to palliative nursing care; and to explore some of the controversies about hope that challenge clinicians.

Definitions and Dimensions of Hope

Hope is an important concept for many disciplines, including philosophy, theology, psychology, nursing, and medicine. Many authors have attempted to define hope and describe its attributes. Some authors are more successful than others in capturing its complexity. A classic nursing theory of hope, developed by Karin Dufault and based on qualitative research involving elderly people with cancer, is particularly notable in its comprehensiveness and expansion of previous psychological models of hope. Dufault described hope as “a multidimensional, dynamic life force characterized by a confident yet uncertain expectation of achieving a future good which, to the hoping person, is realistically possible and personally significant” (p. 380). Dufault also theorized that hope has two interrelated spheres: particularized and generalized. Particularized hope is centered and dependent on specific, valued goals or hope objects. An example is the hope of a terminally ill patient to live long enough to celebrate a particular holiday or event. In contrast, generalized hope is a broader, nonspecific sense of a more positive future that is not directly related to a particular goal or desire. Dufault likened this sphere to an umbrella that creates a diffuse, positive glow on life.

Dufault postulated several dimensions of hope that were incorporated into later research and theories. These dimensions include affective, spiritual, relational, cognitive, behavioral, and contextual aspects of hope. The affective dimension of hope encompasses a myriad of emotions. Of course, hope is accompanied by many positive feelings, including joy, confidence, strength, and excitement. The full experience of hope, however, also includes uncertainty, fear, anger, suffering, and, sometimes, despair. The philosopher Gabriel Marcel, for example, argued that in its fullest sense hope could only follow an experience of suffering or trial. Marcel’s thesis is corroborated by the experiences described by people with cancer who see their disease as “a wake-up call” that has opened their eyes to a greater appreciation for life and an opportunity for self-growth—in other words, an event that has forced them to confront their mortality while also inspiring hope.

The spiritual dimension is a central component of hope. Hopefulness is associated with spiritual well-being and qualitative studies have shown that spirituality and spiritual practices provide a context in which to define hope and articulate hope-fostering activities. These activities include religious beliefs and rituals but extend to broader conceptualizations of spirituality that encompass meaning and purpose in life, self-transcendence, and connectedness with a deity or other life-force. Although spirituality is almost always viewed as a hope-fostering influence, serious illness and suffering can challenge one’s belief and trust in a benevolent deity or be viewed as punishment from God; either interpretation of suffering can result in hopelessness.

Relationships with significant others are another important dimension of hope. Interconnectedness with others is cited as a source of hope in virtually every study, and physical and psychological isolation from others is a frequent threat to hope. Hope levels are positively associated with social support. In addition to family members and friends, patients also have identified nurses as having a significant influence on hope. Despite being vital sources of hope, other people can threaten a patient’s hope by distancing themselves from the patient, showing disrespect, discounting the patient’s experiences, disclosing negative information, or withholding information.

The cognitive dimension of hope encompasses many intellectual strategies, particularly those involving specific goals that require planning and effort to attain. Identifying goals can motivate and energize people, thereby increasing hope. When identifying goals, people assess what they desire and value within a context of what is realistically possible. They appraise the resources necessary to accomplish their goals against the resources that are available to them. They then take action to secure the resources or meet the goals, and they decide on a reasonable time frame in which to accomplish the goals. Active involvement in one’s situation and attainment of goals increases the sense of personal control and self-efficacy, which, in turn, increases hope. If a person repeatedly fails to attain valued goals, hopelessness and passivity can result.

The behavioral, goal-focused thoughts and activities that foster hope are similar to the problem-focused coping strategies originally described by Lazarus and Folkman. This similarity is not surprising, because hope is strongly associated with coping. The exact relationship between the two concepts, however, is unclear. Hope has been identified as a foundation or mediator for successful coping, a method of coping, and an outcome of successful coping. Many strategies that people use to maintain hope have been previously identified as coping methods, and models of maintaining hope overlap substantially with models of coping. Strategies to maintain hope include problem-focused coping methods (e.g., setting goals, actively managing symptoms, getting one’s affairs in order) and emotion-focused strategies (e.g., using distraction techniques, appraising the illness in non-threatening ways).

Contextual dimensions of hope are the life circumstances and abilities that influence hope—for example, physical health,
financial stability, and functional and cognitive abilities. Common threats to hope include acute, chronic, and terminal illness; cognitive decline; fatigue; and impaired functional status. These factors, particularly physical illness and impairment, do not inevitably decrease hope, if people are able to overcome the threat through cognitive, spiritual, relational, or other strategies.

**Influence of Hope and Hopelessness on Adaptation to Illness**

Hope influences health and adaptation to illness. Empirical evidence indicates that diminished hope is associated with poorer quality of life, increased severity of suicidal intent, and higher incidence of suicide. Hopelessness also increases the likelihood that people will consider physician-assisted suicide as an option for themselves. If hopelessness occurs, anxiety and depression can result. Lower levels of hope also are associated with lower self-esteem.

In addition to its influence on psychological states and behaviors, there is some evidence to suggest that hope affects physical states as well. Researchers have found an association between hope and immune function. Moreover, decreased hope is associated with a worse prognosis in several patient populations.

**Variations in Hope Among Different Populations**

The preceding description of hope is derived from studies involving diverse populations, including children, adolescents, adults, and the elderly. In addition, research has been conducted in inpatient, outpatient, and community settings with well persons and those with a variety of chronic and life-threatening illnesses. The experiences of families also have been described. Over these diverse populations and settings, many core concepts have been identified that transcend specific groups. However, some subtle but important differences exist. For this reason, hopefulness in selected populations is addressed in the following sections.

**Hope in Children and Adolescents**

A few investigators have examined hope in pediatric populations. In an early study, Wright and Shontz studied hope in children with chronic disabilities and significant adults in their lives (e.g., parents, teachers, physical therapists). Both the children and the adults were interviewed, allowing for the identification of differences between the two samples. The investigators found that hope for the children in their study was two-dimensional. Hoping involved (1) an awareness of the positive and (2) a sense of time orientation. For younger children, hope was present-focused, whereas older children had a future orientation to hope. Younger children also saw adults as being in control of a situation and were less concerned about assessing how realistic their particular hopes were. In contrast, adults actively assessed the realities of the present and possibilities for the future.

Artinian explored hope in older children, aged 10 to 20 years, who underwent bone marrow transplantation. The findings suggested that ways to reduce stress and instill hope among younger patients and their parents include managing physical discomforts, making children and parents feel cared for, being nonjudgmental when children and parents vent anger, preventing boredom, and assisting with making and altering plans.

A program of research by Hinds and colleagues elucidated the experience of hoping in adolescents. These investigators conducted studies in well adolescents, adolescents undergoing inpatient treatment for substance abuse, and adolescents with cancer. Based on qualitative studies, Hinds defined adolescent hopefulness as “the degree to which an adolescent possesses a comforting or life-sustaining, reality-based belief that a positive future exists for self and others.” Interestingly, inclusion of the phrase “and others” arose from the sample of adolescent cancer patients. Hinds found that only in this sample did adolescents express a concern and articulate their hopes for others. Examples of this attribute included such hopes as “My parents will be O.K. if I die,” and “There will be a cure soon so patient ‘X’ will not die.” This ability to go beyond oneself and hope for others may be influenced by the adolescents’ sense of mortality that accompanies the cancer diagnosis.

Despite the stress of life-threatening illness, many adolescents are able to remain hopeful. Ritchie examined hopefulness and self-esteem in 45 adolescents with cancer. She found that the average hopefulness and self-esteem scores for her sample were as high as those for healthy adolescents. Moreover, high self-esteem was an important predictor of hopefulness. These results suggest that teens are able to respond to serious illness with intact self-esteem and hope.

**Hope and Older Adults**

Numerous studies have examined hope in ill and healthy older adults. Findings from these studies suggest that certain hope-related themes and factors take on special significance for this age group. For example, religious beliefs and spiritual well-being are strongly associated with hope in elders; these factors also were prominent themes in qualitative studies. Common health-related factors, such as impaired physical functioning, poor physical health, decreased mobility, fatigue, and cognitive impairment, are negatively associated with hope in older adults. Although chronic illness that impairs physical functioning is linked with decreased hope, diagnosis of a life-threatening disease, such as cancer, is not associated with low levels of hope. This finding may reflect an attitude among older adults that the quality of life that remains matters more than the quantity.
Among younger European American adults, hope tends to be tied to being productive; personal and professional achievements figure prominently in one’s ability to nurture and maintain hope. In contrast, older adults are more likely to focus on spirituality, relationships, and other factors that are not linked with accomplishment.71,75 Hope-fostering activities include reminiscing, participating in purposeful volunteer activities, religious activities, and connecting with others.

Hope from the Family Caregiver’s Perspective

Family caregivers are an integral component in palliative care. Patients and families influence each other’s hope, and nursing interventions must focus on both groups. Often, the physical and psychological demands placed on family caregivers are great, as are threats to hope.76–78 Threats to hope in caregivers include isolation from support networks and from God; concurrent losses, including loss of significant others, health, and income; and inability to control the patient’s symptoms. Caregivers with poor health status, high fatigue, multiple losses, and sleep disturbances were significantly less hopeful than caregivers without these problems.78

Yates and Stetz76 found that as awareness of dying increased, caregivers hoped for relief from suffering rather than for a cure. Herth79 reported that as death became imminent, the need “to do” for the patient was replaced by a wanting simply “to be” with the patient. In addition, little emphasis was placed on the “future” in caregivers’ descriptions of hope.78

Strategies to maintain hope in family caregivers are similar to those found in patients, with a few differences. Spending time with others in the support network was very important for caregivers. In addition, being able to reprioritize demands helped caregivers conserve much-needed energy. Caregivers also maintained hope through engaging in relaxing activities, such as listening to or playing music, gardening, or watching a sunset.78

Hope in Terminally Ill Patients: Is Hope Compatible with Death?

Research demonstrates that many people are able to maintain hope during acute and chronic illness. Hope also can thrive during the terminal phase of an illness, despite the realization that no cure is possible. In one study, the hope in terminally ill patients and their caregivers actually increased over time as death neared.36,78

Although hope levels may not decrease, the nature of hope often is altered through the dying process. Hope tends to be defined more in terms of “being” rather than “doing.”45,79 Other changes in hope at the end of life include an increased focus on relationships and trusting in others, as well as a desire to leave a legacy and to be well remembered.12,30,81 Spirituality also increases in importance during the terminal phases of illness. In a study of 160 terminally ill patients, decreased spiritual well-being was significantly associated with hopelessness.82 People also adopt specific strategies to foster hope at the end of life.36,45,80,81

Many of these approaches are summarized in Table 26–1. Although hope tends to change in people with terminal illness, maintaining a delicate balance between acceptance of death and hope for a cure often remains an important task up until the time of death, even when people acknowledge that cure is virtually impossible.45,80 The dying person also needs to envision future moments of happiness, fulfillment, and connection. For example, Benzine and colleagues40 reported that people with life-threatening illness needed to dream about possibilities and situations even if the imagined events and goals were unlikely to occur. As one of their participants related,80

Sometimes I let myself imagine that I’ll live until Christmas and sometimes in the night I lie and think about where to put the tree. I know it’s silly but it feels good to think about myself sitting there by the tree with everyone . . . a lovely picture (p. 122).

The first quotation that appears at the beginning of this chapter also captures the ways in which dying patients and their families must walk the tightrope between hope and despair. As Wilkinson44 stated, people confronting the end of their lives must change their perspectives “from dying from a terminal illness to living with a life-threatening illness” (p. 661) in order to maintain hope.
Multicultural Views of Hope

Over the past three decades, understanding of the clinical phenomenon of hope has increased dramatically through theoretical discourse and empirical investigation. Although knowledge regarding the components, processes, and outcomes of hope has grown dramatically, progress in multicultural research on hope has been limited. The samples in many studies that examine hope or hopelessness are ethnically homogeneous, or their ethnic composition is unknown. The studies that do include ethnically diverse samples are small, precluding any comparisons or generalization of findings.

Several excellent European studies have contributed greatly to the general understanding of hope. However, many of these investigations use frameworks and instruments developed by U.S. researchers whose work is founded on homogeneous samples. Moreover, it may be that hopefulness for Europeans is more similar to that of middle-class Americans than it is different.

Some descriptive research using translations of instruments developed by American investigators has been conducted in Korean and Taiwanese cancer patients. Although findings from these studies generally are consistent with those conducted in the United States and Canada, discrete differences may reflect cultural dissimilarities. For example, Lin and associates hypothesized that cultural differences in physicians’ willingness to disclose a cancer diagnosis may have contributed to changes in hope levels in Taiwanese cancer patients.

Despite the growing body of research in diverse samples, existing research may not adequately reflect the experience of hope for people from non-European cultures. Several known cultural differences could certainly limit the applicability of current conceptualizations of hope, especially within the palliative care context. Three issues that theoretically could have a major impact on multicultural views of hope are time orientation, truth-telling, and one’s beliefs about control.

Time orientation is identified as a cultural phenomenon that varies among cultural groups. Some cultural groups, particularly those within the Euro-American culture, tend to be future oriented. Within these groups, people prefer to look ahead, make short- and long-term plans, and organize their schedules to meet goals. Because hope is defined as being future-oriented, with hopeful people more likely to identify and take action to meet goals, members of these future-oriented cultures may possibly appear more hopeful than people who are predominantly present-focused. On the other hand, people who are more focused on the present may be better able to sustain hope at the end of life, when the ability to make long-range goals is hindered by the uncertainty surrounding a terminal diagnosis. Additional research is needed to clarify these relationships.

The value for truth-telling in Western health care systems also may affect hope. Current ethical and legal standards require full disclosure of all relevant health care information to patients. Informed consent and patient autonomy in medical decision-making, two eminent values in American health care, are impossible without this disclosure. Although few would advocate lying to patients, truth-telling is not universally viewed as helpful or desirable. In some cultures, it is believed that patients should be protected from burdensome information that could threaten hope. Truthful, but blunt, communication may also be seen as rude and disrespectful in some cultures, and the feeling of being devalued and disrespected has a negative impact on hope. In addition to the threats to hope that frank discussion is believed to engender, people who prefer nondisclosure of threatening information may be seen as attempting to cling to unrealistic hopes by refusing to listen to discouraging facts about their condition.

A third cultural concept that may affect hope is one’s feeling of being in control. As described earlier, control is a core attribute in many conceptualizations of hope. Although hope can be relinquished to others, including health care providers or a transcendent power, personal control often is central to the hoping process. In Euro-American cultures, applying one’s will and energy to alter the course of an illness or to direct the dying process seems natural and desirable. Advance directives are one culturally sanctioned way in which members of these societies exert control over the dying process. However, this desire for and belief in personal control is not a common feature in many other cultures. In cultures where death is viewed as part of the inherent harmony of living and dying, attempts to exert any influence over the dying process may seem unnatural or inappropriate. People from diverse cultures who take a more passive role in their health care or who do not espouse a desire to control their illness or the dying process may be viewed as less hopeful than people who manifest a “fighting spirit” and active stance.

More research needs to be conducted to test theories of hope in multicultural groups, to ensure the appropriate application of current conceptualizations to diverse cultural groups and to develop new theories that are relevant for these groups. Until this work is done, palliative care clinicians must be cautious in applying current hope theories and sensitive to the possible variations in diverse populations.

Models of Maintaining Hope for People with Life-Threatening Illnesses

Several investigators have identified factors that foster hope and strategies that enable people to sustain hope despite life-threatening or chronic illness. Although there is considerable concordance across these studies regarding many of the major themes, various models emphasize different styles and strategies that demonstrate the diversity in hope-fostering strategies.

As described previously, many people with terminal illness turn to activities and coping strategies that cultivate generalized hope rather than an emphasis on achievement and control. These strategies reflect a sense of peace and acceptance of
death and center on “being” rather than “doing.” These strategies are described in Table 26–1.

In contrast, some models focus more on active, goal-oriented or problem-solving strategies. This author found that adults with leukemia undergoing bone marrow transplantation maintained hope by using many active, cognitive strategies to minimize the psychological distress of life-threatening disease. The resulting model emphasizes that maintaining hope requires a dynamic interplay, or dialectic, between two categories of hope-sustaining strategies: “Dealing with It” and “Keeping It in Its Place.” “Dealing with It” is defined as the process of confronting the negative possibilities inherent in the illness experience, including death, and allowing the full range of thoughts, behaviors, and emotions resulting from the recognition. “Keeping It in Its Place” is defined as the process of managing the impact of the disease and its treatment by controlling one’s response to the disease, prognosis, and therapy (Table 26–2). This model underscores the complex and sometimes contradictory nature of sustaining hope through serious illness. People use multiple strategies that allow them to confront and to avoid the negative aspects of illness and death. Although the strategies used to manage the

threat of death often seem to predominate, these activities occur within a background of recognition and acknowledgment of the possibility of death. This process of negotiating between acknowledgment and management of these fears has been identified in other studies of people with life-threatening illnesses.\(^\text{2,46,104}\)

Gum and Snyder\(^\text{46}\) elaborated a model of hoping that emphasizes the need for people to set goals and take action to achieve them. Although some people continue to search for a cure after receiving a terminal diagnosis, most people eventually accept their diagnosis and mourn the loss of their original goals. At this point, they need to develop and pursue alternative goals that are possible in light of their diminished physical function, end-of-life symptoms, and loss of energy.

These different approaches for maintaining hope are important to describe and understand because they assist the palliative care nurse in designing effective strategies to foster hope. They increase clinicians’ awareness regarding the various ways that people respond to chronic and terminal illness and guide clinicians in their interactions with patients and families to sustain hope. They also help palliative care providers understand difficult or troubling responses, such as unrealistic hopefulness.

The Issue of Unrealistic Hopefulness

Reality surveillance is a feature of many conceptualizations of hope. Often, clinicians, researchers, and theorists believe that mentally healthy people should choose and work toward realistic goals. In these frameworks, adhering to unrealistic hopes or denying reality is a sign of maladaptive cognitions that could lead to negative health outcomes. Therefore, denial and unrealistic hopes and ideas are discouraged and treated as pathological.\(^\text{4,5}\)

Clinical examples of unrealistic hopes that cause consternation are numerous and diverse. For instance, one patient with advanced cancer might hope that his persistent, severe sciatica is from exercise and overuse rather than spinal metastases. The nurse working with this patient may continually contradict his theory, asserting that his denial of the probable, malignant cause of the pain will delay effective treatment. Another patient might insist that a new cure for her illness is imminent, causing distress for the nurse who knows that it is unlikely that a cure will be found and who believes that the patient’s unrealistic hopes will hinder acceptance of and preparation for death.

Despite these concerns, however, some investigators argue that the nurses’ fears may be unfounded. This perspective is based on findings from studies, conducted over the past few decades, which have led social psychologists to question the view that denial and unrealistic hopes are always maladaptive. Instead, these researchers argue that human interpretation of information from the environment is inherently biased and inaccurate.\(^\text{9,45,46}\)

Shelley Taylor and colleagues developed this idea further in their theory of positive illusions, which is based on an extensive program of research spanning more than two decades.\(^\text{105–108}\) They describe positive illusions as general, enduring cognitive patterns, involving error and/or bias, that provide a foundation for successful adaptation to many threatening events, including serious illness. Especially important are unrealistically positive evaluations of the self, exaggerated perceptions of control, and unrealistic optimism about the future.\(^\text{109}\) They support their theory with empirical evidence that denial and positive illusions often are associated with positive outcomes, such as better psychological adjustment to illness, less physical and emotional distress, and even decreased mortality.\(^\text{46,107,108,110,111}\)

In addition to promoting positive outcomes, unrealistic hopes need to be assessed within the context of uncertainty. No one really does know exactly what the future will bring. So, if a person hopes for something in the future that appears highly unlikely, can it be known for certain that it will not occur? Sometimes, patients and families need to focus on this uncertainty to sustain hope.

Another frequent cause of concern is the way in which people exploit uncertainty to maximize hope. For instance, people frequently respond to dire prognostic news with observation that they can always “beat the odds.” Given the fact that no one can predict the future with absolute certainty, it is impossible to predict which individuals with a 2% chance of remission or recovery will actually be cured. Also, consider the case of a person with life-threatening disease who believes that God can provide a cure. Spontaneous “miracle” cures, however rare, have been documented. No one can predict with complete confidence that there is no possibility of a cure. These observations raise the question: do all people who hope against poor odds need help to become more “realistic”? \(^2\)

A third argument against aggressive “reality orientation” for all patients and families is the evidence that unrealistic hopes and illusions often are abandoned over time and without intensive intervention from professionals.\(^\text{12,107,109}\) In other words, most people acknowledge and accept distressing information, but need to do so on their own schedules.

The preceding discussion may seem to imply that clinicians should not be concerned about unrealistic hopefulness. Of course, that is not the case. Despite their adaptive potential, illusions and denial may result in adverse outcomes. For example, unrealistic hopes may lead parents to insist on aggressive, futile therapy that increases their child’s suffering without curing or controlling the disease. Similarly, a person who denies that his illness is terminal may isolate himself from his family to protect his beliefs and avoid contradictory opinions. Unfortunately, in these cases and others, there is insufficient research to inform clinicians fully regarding situations that are potentially maladaptive, and even less guidance about appropriate therapeutic strategies. However, evidence exists that some situations should be viewed with caution and may indicate a need for gentle interventions, such as offering alternative hopes or providing skillful counseling. Table 26–3
lists several questions regarding unrealistic hopes. If the answer to any of these question is “Yes,” then further assessment and possible intervention may be necessary.

**Assessing Hope**

As in all nursing care, thorough assessment of physical and psychosocial factors must precede thoughtful planning and implementation of therapeutic strategies. Therefore, consistent and comprehensive evaluations of hope should be included in the palliative nursing assessment. Some conceptual elements of hope, such as those focusing on meaning and purpose in life, are included in a spiritual assessment. Rarely, however, are comprehensive guides to assessing hope included in standardized nursing assessment forms.

The guidelines produced by Farran, Wilken, and Popovich for the clinical assessment of hope appropriately use the acronym **HOPE** to designate the major areas of evaluation: The areas are **Health**, **Others**, **Purpose in Life**, and **Engaging Process**. The term “engaging process” refers to identifying goals, taking actions to achieve goals, sense of control over one’s situation, and identifying hope-inspiring factors in one’s past, present, and future. In Table 26–4, this framework has been adapted and applied to terminally ill patients. It includes examples of questions and probes that can be used to assess hope.

Like pain, hope is a subjective experience and assessment should focus on self-report. However, behavioral cues can also provide information regarding a person’s state of hope or hopelessness. Hopelessness is a central feature of depression; therefore, behaviors such as social withdrawal, flat affect, alcohol and substance abuse, insomnia, and passivity may indicate hopelessness.

As discussed earlier, the patient’s terminal illness affects the hope of family caregivers, who, in turn, influence the hope of the patients. Therefore, the hope of the patients’ family caregivers and other significant support people also should be assessed.

Over the past decades, researchers from several disciplines have developed instruments to measure hope and hopelessness. The theoretical and empirical literature documents the comprehensiveness and face validity of these tools. Advances in psychometric theory and methods have allowed the evaluation of multiple dimensions of validity and reliability. The development and use of well-designed and well-tested tools has contributed greatly to the science of hope. Although a thorough discussion of these measures is beyond the scope of this chapter, Table 26–5 provides a brief description of several widely used and tested instruments. More complete descriptions and evaluations of these scales can be found elsewhere.11,112

**Assessing Unrealistic Hopes**

<table>
<thead>
<tr>
<th>Question</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Is the focus of the unrealistic hope broad or severe (e.g., complete denial of a disease that has been documented)?</td>
<td></td>
</tr>
<tr>
<td>2. Is the persistence of the unrealistic hope severe, i.e., does it persist despite multiple pieces of information from multiple sources (e.g., family, physicians, nurses) that the hope is unlikely to be realized?</td>
<td></td>
</tr>
<tr>
<td>3. Is the person’s adherence to the unrealistic hope complete, or does the person admit at times that there are limitations and acknowledge negative possibilities? Does the person continually use words such as “knowing” what will happen, rather than acknowledging that what he or she hopes for might not occur?</td>
<td></td>
</tr>
<tr>
<td>4. Does the hope cause the person to engage in reckless behaviors?</td>
<td></td>
</tr>
<tr>
<td>5. Does the hope cause the person to ignore warning signs (e.g., angina, increased pain) that should be treated promptly?</td>
<td></td>
</tr>
<tr>
<td>6. Does the hope cause great distress for family members and significant others?</td>
<td></td>
</tr>
<tr>
<td>7. Has the person become isolated from others, either to avoid their challenges to the unrealistic hope or because others are uncomfortable in responding to the person?</td>
<td></td>
</tr>
<tr>
<td>8. Does it appear that adhering to the hope actually is causing distress and anxiety for the person (who may tacitly doubt or disbelieve in the illusion or hope, but is afraid to discuss that possibility with others)?</td>
<td></td>
</tr>
<tr>
<td>9. Is death imminent, and the unrealistic hopefulness is hindering efforts to get affairs in order, say good-bye, or receive emotional support?</td>
<td></td>
</tr>

Clinicians, theorists, and researchers recognize that nurses play an important role in instilling, maintaining, and restoring hope in people for whom they care. Researchers have identified many ways in which nurses assist patients and families to sustain hope in the face of life-threatening illness.4,87,102,113,114

Table 26–6 provides a summary of nursing approaches to instill hope. A brief perusal of this table reveals an important point about these strategies: For the most part, nursing care to maintain patients’ and families’ hope fundamentally is about providing excellent physical, psychosocial, and spiritual palliative care. There are few unique interventions to maintain hope, and yet there is much nurses can do. Because hope is inextricably connected to virtually all facets of the illness experience—including physical pain, coping, anxiety, and spirituality—improvement or deterioration in one area has repercussions in other areas. Attending to these relationships reminds clinicians that virtually every action they take can influence hope, negatively or positively.

Another vital observation about hope-inspiring strategies is that many approaches begin with the patient and family. The experience of hope is a personal one, defined and determined

<tr>
<td><strong>Health (and Symptom Management)</strong></td>
<td><strong>Rationale</strong></td>
</tr>
<tr>
<td>1. Tell me about your illness. What is your understanding of the probable course of your illness?</td>
<td>Explore the person’s perceptions of the seriousness of the illness and possible trajectories.</td>
</tr>
<tr>
<td>2. How hopeful are you right now, and how does your illness affect your sense of hope?</td>
<td>Determine the person’s general sense of hope and the effect of the terminal illness on hope.</td>
</tr>
<tr>
<td>3. How well are you able to control the symptoms of your illness? How do these symptoms affect your hope?</td>
<td>Uncontrolled end-of-life symptoms have been found to negatively influence hope. 36, 79</td>
</tr>
<tr>
<td><strong>Others</strong></td>
<td><strong>Rationale</strong></td>
</tr>
<tr>
<td>1. Who provides you with emotional, physical, and spiritual support?</td>
<td>Identify people in the environment who provide support and enhance hope.</td>
</tr>
<tr>
<td>2. Who are you most likely to confide in when you have a problem or a concern?</td>
<td>Identify others in whom the person has trust.</td>
</tr>
<tr>
<td>3. What kinds of difficult experiences have you and your family/partner/support network had to deal with in the past? How did you manage those experiences?</td>
<td>Explore experiences of coping with stressful situations.</td>
</tr>
<tr>
<td>4. What kinds of things do family, support people, health care providers do that make you more hopeful? Less hopeful?</td>
<td>Identify specific behaviors that affect hope. Recognize that other people can also decrease hope.</td>
</tr>
<tr>
<td><strong>Purpose in Life</strong></td>
<td><strong>Rationale</strong></td>
</tr>
<tr>
<td>1. What gives you hope?</td>
<td>Identify relationships, beliefs, and activities that provide a sense of purpose and contribute positively to hope.</td>
</tr>
<tr>
<td>2. What helps you make sense of your situation right now?</td>
<td>Identify the ways in which the person makes meaning of difficult situations.</td>
</tr>
<tr>
<td>3. Do you have spiritual or religious practices or support people that help you? If “yes,” what are these practices / people?</td>
<td>Identify if and how spirituality acts as a source of hope.</td>
</tr>
<tr>
<td>4. Has your illness caused you to question your spiritual beliefs? If “yes,” how?</td>
<td>Terminal illness can threaten one’s basic beliefs, and test one’s faith.</td>
</tr>
<tr>
<td>5. How can we help you maintain these practices and personal connections with spiritual support people?</td>
<td>Identify ways in which clinicians and others can support spiritual practices that enhance hope.</td>
</tr>
<tr>
<td><strong>Goals</strong></td>
<td><strong>Rationale</strong></td>
</tr>
<tr>
<td>1. Right now, what are your major goals?</td>
<td>Identify major goals and priorities. Examine whether these goals are congruent with the views of others.</td>
</tr>
<tr>
<td>2. What do you see are the chances that you will meet these goals?</td>
<td>Explore how realistic the person thinks the goals are; if the goals are not perceived as being attainable, assess the impact on hope.</td>
</tr>
</tbody>
</table>
by the hoping person. Although others greatly influence that experience, ultimately the meanings and effects of words and actions are determined by the person experiencing hope or hopelessness. Many approaches used by people with life-threatening illness to maintain hope are strategies initiated with little influence from others. For example, some people pray; others distract themselves with television watching, conversation, or other activities; and many patients use cognitive strategies, such as minimizing negative thoughts, identifying personal strengths, and focusing on the positive.16 For many patients and families, careful observation and active support of an individual’s established strategies to maintain hope will be most successful.

A final point is to remind the reader that family caregivers and other support people should be included in these approaches. Ample evidence exists that patients and people within their support systems reciprocally influence one another’s hope. In addition, family and significant others are always incorporated into the palliative care plan and considered part of the unit of care. Maintenance of hope also is a goal after death, in that hope-restoring and -maintaining strategies must be an integral part of bereavement counseling.175

### Specific Interventions

The framework for the following discussion is adapted from Farran, Herth, and Popovich,11 who articulated four central attributes of hope: experiential, spiritual/transcendent, relational, and rational thought. These areas encompass the major themes found in the literature, and although they are not mutually exclusive, they provide a useful organizing device. This section also includes a brief discussion of ways in which nurses need to explore and understand their own hopes and values in order to provide palliative care that fosters hope in others.

#### Experiential Process Interventions

The experiential process of hope involves the acknowledgment and acceptance of suffering, while at the same time using

the imagination to move beyond the suffering and find hope.87 Included in these types of strategies are methods to decrease physical suffering and cognitive strategies aimed at managing the threat of the terminal illness.

Uncontrolled symptoms, such as pain, fatigue, dyspnea, and anxiety, cause suffering and challenge the hopefulness of patients and caregivers. Timely and adept symptom prevention and management is central to maintaining hope. In home care settings, teaching patients and families the knowledge and skills to manage symptoms confidently and competently also is essential.

Other ways to help people find hope in suffering is to provide them a cognitive reprieve from their situation. One powerful strategy to achieve this temporary suspension is through humor. Several studies and lay publications have identified the central place of humor and lightheartedness in promoting hope.16,44,83,116 According to patients’ views, humor helps put things in perspective and frees the self, at least momentarily, from the onerous burden of illness and suffering. Making light of a grim situation brings a sense of control over one’s response to the situation, even when one has little influence over it. In one study, a respondent noted, “I may not have much control over the nearness of death, but I do have the power to joke about it”36 (p. 1255). Of course, the use of humor with patients and families requires sensitivity as well as a sense of timing. Otherwise, humor becomes a belittling and hope-destroying tool.

Other ways to move people cognitively beyond their suffering is to assist them in identifying and enjoying that which is joyful in life. Engagement in aesthetic experiences, such as watching movies or listening to music that is uplifting, can enable people to transcend their suffering. Sharing one’s own hope-inspiring stories also can help.
Another strategy is to support people in their own positive self-talk. As noted earlier, many people naturally cope with stress by comparing themselves with people they perceive to be less fortunate or by identifying attributes of personal strength that help them find hope. For example, an elderly, married woman with advanced breast cancer may comment that, despite the seriousness of her disease, she feels luckier than another woman with the same disease who is younger or without social support. By comparing herself with less fortunate others, she can take solace in recognizing that “things could be worse.” Similarly, a person can maintain hope by focusing on particular talents or previous accomplishments that indicate an ability to cope with illness. In one study on hope, a woman asserted that her ability to survive an abusive marriage provided evidence that she could also cope with and manage her illness and treatment. People may also cite their high level of motivation as a reason to feel hopeful about the future. Acknowledgment and validation of these attributes supports hope and affirms self-worth for patients and families.

**Spiritual Process Interventions**

Several specific strategies can foster hope while incorporating spirituality. These strategies include providing opportunities for the expression of spiritual beliefs and arranging for involvement in religious rituals and spiritual practices.

Assisting patients and families to explore and make meaning of their trials and suffering is another useful approach. Encouraging patients and families to keep a journal of thoughts and feelings can help people in this process. Suggesting books, films, or art that focuses on religious or existential understanding and transcendence of suffering is another effective way to help people make sense of illness and death.

Palliative care nurses also should assess for signs of spiritual distress and make appropriate referrals to clergy and other professionals with expertise in counseling during spiritual and existential crises. Other spiritual and existential strategies are described in chapters 30, 31 and 32 of this text.

**Relational Process Interventions**

To maximize hope, nurses should establish and maintain an open relationship with patients and members of their support network, taking the time to learn what their priorities and needs are and then addressing those needs in timely, effective ways. Demonstrating respect and interest, and being available to listen and be with people—that is, affirming each person’s worth—are essential.

Fostering and sustaining connectedness among the patient, family, and friends can be accomplished by providing time for uninterrupted interactions, which is especially important in institutional settings. Nurses can increase hope by enlisting help from others to help achieve goals. For example, recruiting friends or arranging for a volunteer to transport an ill person to purchase a gift for a grandchild can cultivate hope for everyone involved. It is important to help others realize how vital they are in sustaining a person’s hope.

Miller recommended that another method of instilling hope is to foster attachment ideation. Attachment ideation is the preoccupation with significant others, such as a child or spouse. To encourage this attachment, a nurse assists a person in identifying and reviewing characteristics that endear and attract the person to the significant other. In this way, the person can focus on the loved one during times of distress or pain, thereby maintaining hope.

**Rational Thought Process Interventions**

The rational thought process is the dimension of hope that specifically focuses on goals, resources, personal control and self-efficacy, and action. Interventions related to this dimension include assisting patients and families in devising and attaining goals. Providing accurate and timely information about the patient’s condition and treatment helps patients and families decide which goals are achievable. At times, gentle assistance with monitoring and acknowledging negative possibilities helps the patient and family to choose realistic goals. Helping to identify and procure the resources necessary to meet goals also is important.

Often, major goals need to be broken into smaller, shorter-term achievements. For example, a patient with painful, metastatic lung cancer might want to attend a family event that is 2 weeks away. The successful achievement of this goal depends on many factors, including adequate pain control, transportation, and ability to transfer to and from a wheelchair. By breaking the larger goal into several smaller ones, the person is able to identify all the necessary steps and resources. Attainment of a subgoal, such as being able to transfer with minimal assistance, can empower patients and families and help energize them to reach more difficult and complex goals.

Supporting patients and families to identify those areas of life and death in which they do have real influence can increase self-esteem and self-efficacy, thereby instilling hope. It also helps to review their previous successes in attaining important goals.

**Programs to Enhance Hopefulness**

In addition to discrete actions that individual nurses take to foster hope, several investigators have developed and tested programs to enhance hope in people with life-threatening illness. Rustøen and colleagues designed a theoretically based group intervention to increase hope in people with cancer. The eight weekly meetings each lasted 2 hours. After an initial introductory session, the subsequent seven sessions focused on a major topic such as believing in oneself, relationships, active involvement, and spiritual beliefs and values. In a randomized trial, Rustøen and coworkers compared the effects of their hope intervention with those of a group self-help/education intervention and a control group. They reported that, 1 to 2 weeks after the interventions, participants in the
hope group showed significantly increased hope scores compared with the other two groups. At the 6-month follow-up, however, these differences were no longer significant.

Herth\textsuperscript{7,102} also designed and tested a Hope Intervention Program, which she evaluated in a group of people with recurrent cancer. Based on her empirically derived theory of hope, the intervention consists of eight sessions delivered in a nurse-facilitated group setting. Six sessions focus on strategies that specifically address the four hope processes: experiential, relational, spiritual/transcendent, and rational thought. During the final session, participants develop an individual plan with strategies to maintain and foster hope. When Herth tested this intervention, she found significantly increased hope levels in the treatment group compared with two control groups. These significant differences persisted at the 3-, 6-, and 9-month follow-up measurements.\textsuperscript{102}

Hinds and colleagues developed a Psychosocial Research–Translation Team to integrate evidence-based hope intervention guidelines into the cancer care department at St. Jude Children's Hospital.\textsuperscript{119} Using this innovative approach, the multidisciplinary team reviewed the literature on hope and interviewed experts on the topic. The team used this information to develop its own definition of hope and to identify potential projects aimed at translating the evidence-based guidelines on hope into practice. These projects included (1) adding information about hope to the parent handbook; (2) developing patient, parent, and staff educational sheets about hope; (3) developing a telephone hotline that allows for the efficient and personal delivery of messages of hope to callers; and (4) designing and launching websites about hope. This program demonstrates the creative and diverse approaches that health care providers can use to support and promote hope among patients and families facing life-threatening illnesses.

### Ensuring the Self-Knowledge Necessary to Provide Palliative Care

Providing holistic palliative care requires a broad range of skills. Astute management of physical symptoms and a solid command of technical skills must be matched with an ability to provide psychosocial and spiritual care for patients and families at a time of great vulnerability. To nurture these latter skills, nurses should continually reflect on and evaluate their own hopes, beliefs, and biases\textsuperscript{6,120} and identify how these factors influence their care. Within particular clinical situations, they should evaluate how patients’ and families’ responses and strategies to maintain hope affect them. For example, does it anger or frustrate the nurse that the patient seems to refuse to acknowledge that his or her disease is incurable? Is this anger communicated nonverbally or verbally to the patient or family? In addition to self-reflection, it is important for palliative care nurses to maintain hopefulness while working with dying patients by engaging in self-care activities.

### Summary

Hope is central to the human experience of living and dying, and it is integrally entwined with spiritual and psychosocial well-being. Although terminal illness can challenge and even temporarily diminish hope, the dying process does not inevitably bring despair. The human spirit, manifesting its creativity and resiliency, can forge new and deeper hopes at the end of life. Palliative care nurses play important roles in supporting patients and families with this process by providing expert physical, psychosocial, and spiritual care. Sensitive, skillful attention to maintaining hope can enhance quality of life and contribute significantly to a “good death” as defined by the patient and family. Fostering hope is a primary means by which palliative care nurses accompany patients and families on the journey through terminal illness.

Bereavement

What is it like to know you are dying? I will tell you. I just want to go—just to go out in a flash like a light. This knowing that the end is coming and of all I will leave behind is killing me. How do you say goodbye, let go?—A patient

On June 9, 2004, a faculty member died after a valiant battle to live. She had been afflicted with a type of cancer for which she received a bone marrow transplant. The transplant failed, and this gifted academician died leaving a bereft husband and five children, three of whom were triplets. On the same day, a young girl died. She was the daughter of a faculty member at the same academic program. The faculty member chose not to divulge the slow decline of her lovely 19-year-old daughter, thereby encapsulating the group to which she needed to reveal her sad news. The faculty was devastated to have encountered death in the first person among their ranks, wanting to offer support and condolences to the immediate family—which they did—and also confronting their own grief. Faculty members walked around their school in a daze grieving for their losses. They were the walking wounded.

Bereavement takes many forms. It is influenced first and foremost by culture. In Victorian times, bereaved women in the northeastern United States wore black for a year and used black-edged stationery, while men wore a black armband for a matter of days before resuming their regular activities. Bereavement is also influenced by religious practice, the nature of the relationship with the deceased, the age of the deceased, and the manner of death. In this chapter, the impacts of social and cultural forces on the form of bereavement are examined.

Changes have occurred in what is considered appropriate to the expression of grief. The wearing of black by a widow (“widow's weeds”) for the remainder of her life and the presumption that grief will be “resolved” within a year are no longer societal expectations. There are other expectations, however, that color the expressions of bereavement, loss, mourning, and grief. Given that greater emphasis is given to the discussion of bereavement and grief, it behooves us to define these terms and examine their related elements.
A Matter of Definition

Bereavement

With the pronouncement of death, those who have the closest blood or legal connections to the deceased are considered bereaved. Stated simply, “bereavement is defined as the state of having experienced the death of a significant other.” Bereavement confers a special status on the individual, entailing both obligations and special rights. The obligations concern disposition of the body and any attendant ceremonies, as well as disposal of the worldly goods of the deceased, unless indicated otherwise in a legal document such as a last will and testament. The rights include dispensation from worldly activities such as work and, to a lesser degree, family roles for a variable period of time. Before an expanded discussion of bereavement is undertaken, it is important to distinguish the concept of bereavement from related terms as loss, mourning, and grief.

Loss

Loss is a generic term that signifies absence of an object, position, ability, or attribute. More recently it also has been applied to the death of an animal or person. Absence or loss of the same phenomenon has different implications, depending on the strength of the relationship to the owner. For example, loss of a dog with which there was an indifferent relationship results in less emotional disruption for the owner than the loss of a dog that was cherished. The term is often applied to the death of an individual, and it is the bereaved person who is considered to have experienced a loss. Robinson and McKenna noted three critical attributes of loss:

1. Loss signifies that someone or something one has had, or ought to have had in the future, has been taken away.
2. That which is taken away must have been valued by the person experiencing the loss.
3. The meaning of loss is determined individually, subjectively, and contextually by the person experiencing it.

As is evident from the example of the loss of a dog, the individual determination of meaning indicates that the second attribute suggested by Robinson and McKenna, namely that what was lost was valued, is not necessarily congruent with the third attribute, which indicates individual evaluation, and is in fact superfluous. A loss occurs and its meaning is determined by the person who sustained the loss. The attributes of loss can be reformulated as follows:

1. Loss signifies the absence of a possession or future possession.
2. Each loss is valued differently and ranges from no or little value to great value.
3. The meaning of the loss is determined primarily by the individual sustaining it.

This suggests that it is wiser not to make assumptions about loss but to query further as to its meaning to the individual.

Mourning

Mourning has been described in various ways. Kagawa-Singer described mourning as “the social customs and cultural practices that follow a death.” This definition highlights the external manifestations of the process of separation from the deceased and the ultimate reintegration of the bereaved into the family and, to varying degrees, society. Durkheim, one of the founders of sociology, stated that “mourning is not a natural movement of private feelings wounded by a cruel loss; it is a duty imposed by the group” (p. 443). This duty is participation in the customary rituals appropriate to membership in a given group. Participation in such rituals has meaning for the mourner and group. These rituals and behaviors acknowledge that a loss has occurred for the individual and the group, and that the individual and the group are adjusting their relationships so as to move forward without the presence of the deceased individual.

DeSpelder and Strickland highlighted two important aspects of mourning. They stated that mourning is “the process of incorporating the experience of loss into our ongoing lives” and also “the outward acknowledgment of loss” (p. 207). That outward acknowledgment consists of participation in various death and bereavement rituals. As noted, these vary by religious and cultural traditions as well as by personal preferences. Martinson described the variation in practices in eastern Asia due to the influences of folk practices, Confucianism, Buddhism, and Christianity.

Whereas ancestor worship is important to varying degrees in Asia, Latin cultures believe in “the interdependence between life and death,” a belief that reflects “the value that is placed on the continuity of relationships between the living and the dead.” This relationship is considered sacred and is expressed openly in some of the ritual practices dedicated to the dead. These practices have many functions, including signifying respect for the deceased and providing a mechanism for the expression of feelings by the bereaved.

Grief

Grief has been defined as “a person’s emotional response to the event of loss,” as the “state of mental and physical pain that is experienced when the loss of a significant object, person, or part of the self is realized,” and as “the highly personal and subjective set of responses that an individual makes to a real, perceived, or anticipated loss.” There are numerous definitions of grief, and these are only illustrative of variations on a theme. The process of grief has been studied and reformulated, phases identified, types proposed (anticipatory, complicated, disenfranchised), and expressions of grief described.
Given that nurses work largely with individuals and families but in some cases also with communities, several sections of this chapter focus on grief as it relates to these different entities. However, even in those sections that putatively deal with associated topics, the subject of grief is related and may be interwoven. With these preliminary definitions as a basis, bereavement, grief, and mourning can now be addressed in greater depth.

"The Process of Bereavement"

The process and meaning of bereavement vary depending on a number of factors, including age, gender, ethnicity, cultural background, education, and socioeconomic status. For African American widows, story-telling was the means by which the bereavement experience was described. The themes identified in a study of these widows included awareness of death, caregiving, getting through, moving on, changing feelings, and financial security. These themes describe well the concerns of bereavement.

To measure core bereavement phenomena, Burnett and colleagues identified 17 items that they considered central to the process of bereavement. They categorized these items under three subscales, namely images and thoughts (e.g., “Do you think about ‘X’?”), acute separation (e.g., “Do you find yourself missing ‘X’?”), and grief (e.g., “Do reminders of ‘X,’ such as photos, situations, music, or places, cause you to cry about ‘X’?”). Although the purpose of this scale is to “assess the intensities of the bereavement reaction in different community samples of bereaved subjects,” the bereavement reaction that is being addressed is grief.

The distinction between grief and depression in the bereaved is an important one. As Middleton and associates concluded, “The bereaved can experience considerable pain and yet be coping adaptively, and they can fulfill many depressive criteria yet at the same time be experiencing phenomena that are not depressive in nature.” Even in individuals with a history of “sadness or irritability” before bereavement, although they may have more intense expressions of grief, the rate of recovery is the same as for those without such a history. Other authors are not as sanguine and caution that subsyndromal symptomatic depressions are “frequently seen complications of bereavement that may be chronic and often are associated with substantial morbidity.”

Boelen and coworkers pointed out that traumatic grief is distinct from bereavement-related depression and anxiety. Identifying these differences clinically is essential for appropriate treatment. A Bereavement Risk Questionnaire with 19 possible factors for identifying complicated bereavement was distributed to 508 hospice bereavement coordinators. Of these, 262 (52%) responded. Significant risk factors for caregivers included lack of social support, caregiver history of drug or alcohol abuse, poor coping skills, history of mental illness, and “patient is a child.”

Bereavement-related grief was conceptualized by Rubin and Schecter into two pathways: “a dimension concerned with how the bereaved individual functions following loss” and “a dimension concerned with the nature of that individual’s relational bond to the deceased.” They observed further that loss involves disruption of multiple spheres of the individual’s life. The two-track model of bereavement was developed as a means of understanding and addressing the bereavement process and its outcome: “Track I focuses on the physiological, somatic, affective, cognitive, social and behavioral factors that are affected by loss—and Track II examines ways of transforming the bereaved’s attachment to the deceased and establishing new forms of ongoing relationship to the memories of that person.” In essence, bereavement involves adjusting to a world without the physical, psychological, and social presence of the deceased.

Although Bernard and Guarnaccia found differences between husbands and daughters of breast cancer patients, ultimately the family role relationship affected bereavement adjustment. The quality of the family relationship, with greater expression of family affect and cohesion, was found to be predictive of the expression of fewer grief symptoms over time.

Bereavement becomes complicated (in the literature and in life) when adjustment is impeded, as in posttraumatic stress disorder. Whether such bereavement occurs as a result of vehicular accident, war, or natural disaster, the suddenness or overwhelming nature of the event dislodges the sense that all is well with the world. Even in instances in which an elective medical procedure such as abortion occurs, the emotional response may not become evident until many years later.

Death before its time, as in children and young and middle-aged adults, not only affects the bereaved directly but also affects the social roles of the survivors, which require readjustment. The idea that parental outcomes are worse when a child’s death is by suicide was not confirmed empirically. Another myth is that divorce is more common among bereaved couples than in the general population. The empirical evidence is insufficient either to substantiate or disconfirm this myth.

Hutton and Bradley, in their study of the bereaved siblings of babies who were casualties of sudden infant death, were uncertain as to whether these siblings actually exhibited more behavioral problems or were thought to be doing so by mothers whose perceptions were distorted. The need for greater attention to children who are bereaved was underscored by Mahon, who observed that most of the literature in this area concerns “parental impressions of children’s grief and studies of adolescent bereavement.” The hesitancy of children to exhibit their own sadness so as not to upset their parents requires that professionals encourage parents to give their children permission to be sad when that is how they feel. By taking care of their parents, children may not receive the attention they require. In a study that sought to identify those factors that helped or hindered adolescent sibling bereavement, a
youngster stated: "What helped me the most was my mother who was totally honest with me from the time Sarah got sick through her death. My mother took the time to listen to how I felt as well as understand and hug me."

Formal programs of bereavement for children’s support include peer support programs and art therapy programs. Institutions with bereavement programs, whether for children or adults, often send cards at the time of a patient’s death, on the birthday of the deceased, and at 3, 6, 12, and 24 months after the death. Pamphlets with information about grief, a bibliography of appropriate readings, and contact numbers of support groups are also helpful. Lev and McCorkle cited Potocky’s finding that short-term programs of two to seven sessions or meeting as needed were the most effective. Madocks observed that routine bereavement care can be helpful in identifying people at risk for complicated grieving. Family bereavement programs also have been found to lead to improved parenting, coping, and caregiver mental health. Given that the best therapy is prevention, palliative care teams who identify caregivers at risk for bereavement maladjustment can intervene early to prevent long term difficulties.

Attention to bereavement support has also been given by institutional trauma programs, in emergency departments, and in critical care departments. All of these programs maintain contact with the bereaved so as to provide support and make referrals to pastoral care personnel and other professionals as needed. Indeed, the combination of “religious psychotherapy” and a cognitive-behavioral approach was observed to be helpful to highly religious bereaved persons. Religious psychotherapy for a group of Malays who adhered to the religion of Islam consisted of discussion and reading of verses of the Koran and Hadith, the encouragement of prayers, and a total of 12 to 16 psychotherapy sessions. Targeting of the follow-up approach to the characteristics of the population eschews the notion that “one size fits all.”

A bereavement support group intervention was demonstrated to have a significant impact on the grief of homosexual men who were or were not seropositive for the human immunodeficiency virus (HIV-1). The need for support was found to be all the more necessary for bereaved women living with HIV, who “may be at increased risk for bereavement complicated with psychiatric morbidity and thoughts of suicide” (Summers et al., p.225). Cognitive processing and finding meaning were found to have immunologic and health benefits independent of the baseline health status of bereaved HIV-positive homosexual men. This outcome has implications for the approaches nurses use with other bereaved clients. Cognitive processing and finding meaning can be helpful to a variety of clients. However, older persons have been noted to be more reluctant to express their feelings. Nurses can be helpful to these clients by encouraging them to express their feelings and being available when needed.

Aside from such proactive approaches for all bereaved persons, Sheldon reported the following predisposing factors for a poor bereavement outcome: ambivalent or dependent relationship; multiple prior bereavements; previous mental illness, especially depression; and low self-esteem. Billings added prior physical health problems to these predisposing factors. Sheldon identified the following factors at the time of death: sudden and unexpected death, untimely death of a young person, preparation for the death, stigmatized deaths (e.g., AIDS, suicide, culpable death), sex of the bereaved person (e.g., elderly male widower), caring for the deceased person for >6 months, and inability to carry out valued religious rituals. The impact of trauma characterized by violence on bereavement was found by Kaltman and Bonanno to lead to posttraumatic stress disorder symptoms beyond those of normal grief.

Finally, after the death, such factors as level of perceived social support, lack of opportunities for new interests, and stress from other life crises, as well as dysfunctional behaviors and attitudes appearing early in the bereavement period, consumption of alcohol and drugs, smoking, morbid guilt, and the professional caregiver’s gut feeling that this patient will not do well are predictive of poor outcomes. Knowledge of and alertness to such predisposing factors are useful for the provision of help, both lay and professional, early in the course of the bereavement so as to prevent further debilitating events.

The Nature of Grief

Rando observed that, although Freud was not the first person to examine the effects of bereavement, he nonetheless is taken as an important point of departure. The observation that grief is a normal process and that “a lost love object is never totally relinquished” are congruent with current thinking. The notion that one needs to totally “let go” of the beloved, ascribed to Freud on the basis of some of his work, has influenced professionals to the current day.

The initiation of the modern study of death and dying, however, especially in America, is often attributed to Erich Lindemann, a physician at Massachusetts General Hospital, who responded to the survivors of a fire in Boston’s Coconut Grove nightclub. Five hundred persons died as a result of the fire, which took place on Thanksgiving eve, 1942. Lindemann, a psychiatrist, was interested at the time in the emotional reaction of patients to body disfigurement and plastic surgery. With this background, “Lindemann was struck by the similarity of responses between his patients’ reactions to facial disfigurement or loss of a body part and the reactions of the survivors of the fire” (p. 105).

Lindemann’s study of 101 patients included (1) psychoneurotic patients who lost a relative during the course of treatment, (2) relatives of patients who died in the hospital, (3)bereaved disaster victims (Coconut Grove fire) and their close relatives, and (4) relatives of members of the armed forces. Based on these patients, he determined the five indicators that are “pathognomonic for grief”:

1. sensations of somatic distress, such as tightness in the throat, choking and shortness of breath;
2. intense preoccupation with the image of the deceased;
3. strong feelings of guilt;
4. a loss of warmth toward others with a tendency to respond with irritability and anger; and
5. disoriented behavior patterns.
Lindemann coined the term “grief work” to describe the process by which individuals attempt to adjust to their loss.47

Various theorists have developed a series of stages and phases of grief work.49–52 The best known of these to the general public are the stages formulated by Elizabeth Kübler-Ross. Proposed for those facing a death, these stages have also been applied to those experiencing a loss. Kübler-Ross53 identified five stages: denial and isolation, anger, bargaining, depression, and acceptance. The commonality among all theorists of the stages of grief is that the individual moves through (1) notification and shock, (2) experience of the loss emotionally and cognitively, and (3) reintegration. Rando,54 for example, used the terms avoidance, confrontation, and reestablishment for these three phases. Building on the work of Worden,55 Corr and Doka56 propose the following tasks:

1. To share acknowledgment of the reality of death
2. To share in the process of working through to the pain of grief
3. To reorganize the family system
4. To restructure the family’s relationship with the deceased and to reinvest in other relationships and life pursuits

In regard to the last task, some dispute has arisen concerning the degree to which separation from the deceased must occur. Klass and associates57 made the compelling argument that such bonds continue. They advocated that “survivors hold the deceased in loving memory for long periods, often forever,” and that maintaining an inner representation of the deceased is normal rather than abnormal. Winston’s study of African-American grandmothers demonstrated that they maintained strong bonds with the deceased.58

The second area of disension and new consensus is the expectation that grief must be resolved within a year, which is not to say that the expected trajectory of grieving is one in which grief continues at an intense pitch for years. The question of continuing bonds and the length of the grief process are addressed again at the close of the chapter. In this next section, types of grief are examined.

Types of Grief

The types of grief examined in this section are not exhaustive of all types of grief but rather encompass the major categories.

Anticipatory Grief

Anticipatory grief shares similarities with other forms of grief. It is also different. The onset may be associated with the receipt of bad news.5 Anticipatory grief must be distinguished from the concept of forewarning. An example of forewarning is learning of a terminal diagnosis. Anticipatory grief is an unconscious process, whereas forewarning is a conscious process. With forewarning of a terminal diagnosis the question is, “What if we do?” With a death that question becomes, “What if we had done?” With the former question, there is the potential for hope; with the latter query, there may be guilt.

Stephenson’s description of a roller-coaster experience of hope followed by negative experience countered by hope. Even with forewarning, preparation for loss may not occur, given that this may be perceived to be a betrayal of the terminally ill person. There have also been instances of family members unconsciously preparing for the death of an individual and going through the grieving process, only to have that person recover to find no place in the lives of his or her loved ones. This is an example of anticipatory grief.

The question of the utility of forewarning is one of how this time is used. If it is used to make some preparation for role change, such as becoming familiar with the intricacies of the role the terminally ill person plays in the family (e.g., mastering a checking account or other financial aspects of the family), such time may be used to the benefit of all concerned. On the other hand, anticipatory grieving that results in reinvestment of emotional energy before the death of the terminally ill person is detrimental to the relationship.

Byrne and Raphael59 found that “widowers who were unable to anticipate their wife’s death, even when their wife had suffered a long final illness, had a more severe bereavement reaction.” (The term “anticipate” is being used by Byrne and Raphael in the sense of forewarning.) Family members and friends are “warned” when their loved one is diagnosed with certain disease entities such as cancer with metastases. If the primary problem is Alzheimer’s disease, there may be a long decline in which, ultimately, familiar figures are no longer recognized. In either situation, the death of the ill person may be experienced both with sadness and with a sense of relief that the caregiving burden is no more. The price of that relief is that the patient is no more.

The sense of relief experienced by caregivers is often a source of guilt feelings about wishing the patient dead. It is important to clarify for the family member or significant other that feelings of relief from being freed of the caregiver burden are not equivalent to wishing someone dead. A woman who experienced relief from not having to care for her large husband was assisted to examine this distinction and consequentially was able to grieve uncomplicated by feelings of guilt. Further, persons who have cared for a dying person may experience a sense of accomplishment knowing that they have done everything they could for their loved one.60 Schultz and associates61 pointed out that bereavement is “not only a phenomenon that affects caregivers after the death but also . . . one that affects many caregivers before the death occurs” (p. 8).

Duke,62 in a qualitative study of anticipatory grief, enlarged the understanding not so much of anticipatory grief but of the status changes of widowhood. She interviewed five spouses in the second year of their bereavement. Although the findings may have been biased by the distortion of hindsight, they provide much food for thought. The research identified four areas of change63: role change from spouse to caregiver during the illness, followed by loss of those roles in bereavement and
needing to be cared for; relationship changes from being with spouse to being alone; coping changes from being in suspense to being in turmoil; and the change from experiencing and gathering memories to remembering and constructing memories. It is interesting that these findings reflect the general changes that occur over a terminal illness and not the experience of anticipatory grief. Anticipatory grief, as noted previously, is unconscious preparation for status change and not a conscious, deliberative process. Anticipatory grief is contrasted with what is termed uncomplicated grief.

**Uncomplicated Grief**

Uncomplicated grief, or normal grief, was described by Cowles as dynamic, pervasive, highly individualized, and a process. Worthington depicted a linear model of grief based on adjustment. In this model, an individual in a normal emotional state experiences a loss that causes a reaction and an emotional low; subsequently, the individual begins a recovery to his or her former state. This process of recovery is occasioned by brief periods of relapse, but not to the depths experienced previously. Ultimately the individual moves to adjustment to the loss. Although this description simplifies the turmoil that may be experienced, discussion of expressions of grief later in this chapter captures the physical, psychological, behavioral, and social upset that characterizes even uncomplicated grief.

Niemeyer offered a vital new perspective by focusing on meaning reconstruction. He developed a set of propositions to capture adaptation to loss:

1. Death as an event can validate or invalidate the constructions that form the basis on which we live, or it may stand as a novel experience for which we have no constructions.
2. Grief is a personal process, one that is idiosyncratic, intimate, and inextricable from our sense of who we are.
3. Grieving is something we do, not something that is done to us.
4. Grieving is the act of affirming or reconstructing a personal world of meaning that has been challenged by loss.
5. Feelings have functions and should be understood as signals of the state of our meaning-making efforts.
6. We construct and reconstruct our identities as survivors of loss in negotiations with others.

Niemeyer viewed meaning reconstruction as the central process of grief. The inability to make meaning may lead to complications.

**Complicated Grief**

In her discussion of complicated mourning, Rando made observations applicable to complicated grief. She observed that, after a suitable length of time, the mourner is attempting to “deny, repress, or avoid aspects of the loss, its pain, and its implications and . . . to hold onto, and avoid relinquishing, the lost loved one.” These attempts, or some variants thereof, cause the complications in mourning.

Researchers have identified the diagnostic criteria for complicated grief disorder. These criteria include “the current experience (>1 year after a loss) of intense intrusive thoughts, pangs of severe emotion, distressing yearnings, feeling excessively alone and empty, excessively avoiding tasks reminiscent of the deceased, unusual sleep disturbances, and maladaptive levels of loss of interest in personal activities.” Other researchers have underscored the need for the specification of complicated grief as a unique disorder and have developed an inventory of complicated grief to measure maladaptive symptoms of loss. The Inventory of Complicated Grief is composed of 19 items with responses ranging from “Never” to “Rarely,” “Sometimes,” “Often,” and “Always.” Examples of items include, “I think about this person so much that it’s hard for me to do the things I usually do”; “Ever since she (or he) died it is hard for me to trust people”; “I feel that it is unfair that I should live when this person died”; and “I feel lonely a great deal of the time ever since she (or he) died.” This inventory may be helpful to health care practitioners because it differentiates between complicated grief and depression. Finally, it is the severity of symptomatology and the duration that distinguishes abnormal and complicated responses to bereavement.

The Inventory of Complicated Grief was used by Ott with 112 bereaved participants in a study in which those identified as experiencing complicated grief were compared with those who were not. Those with complicated grief both identified more additional life stressors and felt they had less social support than the other bereaved individuals in the study.

It should be noted that there is some concern among professionals that what is a normal process is being medicalized by health care practitioners. Complicated grief, however, may require professional intervention. More is said about this later in the chapter. Bearing this in mind, disenfranchised grief poses different but potentially related problems.

**Disenfranchised Grief**

Doka defined disenfranchised grief as “the grief that persons experience when they incur a loss that is not or cannot be openly acknowledged, publicly mourned, or socially supported.” Doka continued, “The concept of disenfranchised grief recognizes that societies have sets of norms—in effect, grieving rules—that attempt to specify who, when, where, how, how long, and for whom people should grieve” (p. 272). In addition, these norms suggest who may grieve publicly and expect to receive support.

Those who are grieving the loss of relationships that may not be publicly acknowledged—for example, with a mistress or with a family conceived outside a legally recognized union, or in some cases with stepfamilies, colleagues, or friends—are not accorded the deference and support usually afforded the bereaved. Further, nonsanctioned relationships, either heterosexual or homosexual, may result in the exclusion of individuals not legitimated by
blood or legal union. Individuals in homosexual relationships of long standing who care for their partners throughout their last illness, may find themselves barred both from the funeral and from the home that was shared.24

For some time, infection with HIV was hidden from the community, thereby depriving both the infected and their caregivers of support. The AIDS quilt has done much to provide a public mourning ritual but has not alleviated the disenfranchised status of homosexual or lesbian partners. The result is what has been termed “modulated mourning.”274 This response to stigmatization constrains the public display of mourning by the griever. In this situation, the griever is not recognized.

There are other instances in which a loss has not been legitimized. Loss resulting from miscarriage or abortion has only recently been recognized. In Japan, a “cemetery” is devoted to letters written by families each year telling miscarried or aborted children about the important events that occurred in the family that year and also expressing continued grief at their loss. Grieving in secret is a burden that makes the process more difficult to complete. Disenfranchised grief may also be a harbinger of unresolved grief.

Unresolved Grief

Unresolved grief is a failure to accomplish the necessary grief work. According to Rando,24 a variety of factors may give rise to unresolved grief, including guilt, loss of an extension of the self, reawakening of an old loss, multiple loss, inadequate ego development, and idiosyncratic resistance to mourning (pp. 64–65). In addition to these psychological factors, such social factors as social negation of a loss, socially unspeakable loss, social isolation and/or geographic distance from social support, assumption of the role of the strong one, and uncertainty over the loss (e.g., a disappearance at sea) may be implicated in unresolved grief (pp. 66–67). By helping significant others express their feelings and complete their business before the death of a loved one, unresolved grief and the accompanying manifestations can be prevented to some extent.

Eakes and coworkers25 questioned whether closure is a necessary outcome. They explored the concept of “chronic sorrow” in bereaved individuals who experienced episodic bouts of sadness related to specific incidents or significant dates. These authors suggested the fruitfulness of maintaining an open-ended model of grief. With this in mind, grief is always unresolved to some degree; this is not considered pathological but rather an acknowledgment of a death.

Expressions of Grief

Symptoms of Grief

In some of the earlier sections of this chapter, various manifestations of grief were mentioned. In this section, expressions of grief that are within the range considered normal in this society are described. It is important to note that what is considered appropriate in one group may be considered deviant or even pathological in another.

In Table 27–1, physical, cognitive, emotional, and behavioral symptoms of grief are presented. Table 27–1 is not exhaustive of all of the potential symptoms but rather is illustrative of the expressions and manifestations of grief. What distinguishes so-called normal grief is that it is usually self-limited. Manifestations of grief at 1, 3, and 15 months after the death are not the same in intensity, nor are the outward manifestations that are the expressions of mourning.

Mourning

O’Gorman26 contrasted death rituals in England with those in Ireland. She recalled the “Protestant hushed respectfulness which had somehow infiltrated and taken over a Catholic community.”276 The body was taken from the home by the funeral director. Children continued with school and stayed with relatives; they were shielded from the death. By way of contrast, in an Irish wake, “The body, laid out by a member of the family, in order to receive a ‘special blessing,’ would be in the parlour of a country house surrounded by flowers from the garden and lighted candles.” The children, along with the adult members of the family, viewed the corpse. “When visitors had paid their last respects they would join the crowd in the kitchen who would then spend all night recounting stories associated with the dead person.”276 O’Gorman noted the plentiful availability of alcohol and stated, “By the end of the night to the uninitiated the event would appear to be more like a party than a melancholy event.” Although O’Gorman initially found this distasteful, she “now believes that rituals like the Irish celebrate death as a happy occasion and bestow grace upon those leaving life and upon a community of those who mourn them.”276

The Irish wake, like the reception held in a church basement, hall, restaurant, or private home, serves not only for the expression of condolences but also as an opportunity to reinforce the connections of the community. Anyone familiar with such events knows that a variety of social and business arrangements are made by mourners both within and outside the immediate family. And although some gatherings are more reserved and others luster, giving the deceased a good send-off (“good” being defined by the group) is central to each. The good send-off is part of the function of the funeral as a peculiar rite—that is, as a means of atoning for the sins of the mortal being and as preparation for life in the afterworld.277 Fulton27 noted two other functions of funerals, namely integration and separation. The former concerns the living; the latter refers to separation from the loved one as a mortal person. The value of the Irish wake, which in the United States may look more like the Protestant burial O’Gorman describes, is the time spent together sharing stories and feelings. In the Irish wake as practiced in Ireland, one is not alone with one’s feelings but in the company of others who are devoting the time to mourning (integration).
This devotion of time to mourning is also found in the Jewish religion, where the bereaved sit “shiva,” usually for 7 days. In Judaism, the assumption is that the bereaved are to focus on their loss and the grieving of that loss. They are to pay no attention to worldly considerations. This period of time of exemption from customary roles may facilitate the process. Certainly having a “minion,” in which 10 men and women (10 men for Orthodox Jews) say prayers each evening, reinforces the reality of the death and the separation. For the Orthodox, the mourning period is 1 year.

A very different pattern is practiced by the Hopi in Arizona. The Hopi have a brief ceremony with the purpose of completing the funeral as quickly as possible so as to get back to customary activities. The fear of death and the dead and of spirits induces distancing by the Hopi from nonliving phenomena.

Stroebe and Stroebe contrasted Shinto and Buddhist mourners in Japan with the Hopi. Both Shinto and Buddhist mourners practice ancestor worship. As a result, the bereaved can keep contact with the deceased, who become ancestors. Speaking to ancestors as well as offering food is accepted practice.

In contrast to this Japanese practice, what occurs in the United States is that those bereaved who speak with a deceased person do so quietly, hiding the fact from others, believing others will consider it suspect or pathological. It is, however, a common occurrence. Bringing food to the ancestor or (e.g., to celebrate the Day of the Dead) to the cemetery, is part of the mourning practice in Hispanic and many other societies.

Practices, however, change with time, although one can often find the imprint of earlier rituals. The practice of saving a lock of hair or the footprint of a deceased newborn may have evolved from the practice in Victorian times of using hair for mourning brooches and lockets. As a salesperson of these items commented, “They liked to be reminded of their dead in those days. Now it’s out of sight, out of mind.”

These mourning practices provide continuing bonds with the deceased and offer a clue to the answer to the question posed for the last section of this chapter: When is it over? Before addressing this question, another needs to be raised, and that is the question of support.

### A Question of Support

**Formal Support**

Many of the mourning practices noted previously provide support by the community to the bereaved (Table 27–2). Formal support in the Jewish tradition is exemplified by the practice of attending a minyan for the deceased person. The minyan expresses support for the living. It is formal in that it is prescribed behavior on the part of observant Jews and incorporates a prayer service.

Other examples of formal support include support groups such as the widow-to-widow program and the Compassionate Friends, Inc. for families of deceased children. The assumption underlying the widow-to-widow program is that grief and mourning are not in and of themselves pathological and that lay persons can be helpful to one another. The widow-to-widow program provides a formal mechanism for sharing one’s...
emotions and experience with individuals who have had a similar experience. The Widowed Persons Service offers support for men and women via self-help support groups and a variety of educational and social activities. The Compassionate Friends, Inc., also a self-help organization, seeks to help parents and siblings after the death of a child. Other support groups may or may not have the input of a professional to run the group.

Support groups may be open-ended (i.e., without a set number of sessions), or they may be closed and limited to a particular set of individuals. Support groups with a set number of sessions have a beginning and end and are therefore more likely to be closed to new members until a new set of sessions begins. Open-ended groups have members who stay for varying lengths of time and may or may not have a topic for each session.

Other formal support entails working with a therapist or other health care provider (bereavement counseling). Arnold suggested that the nurse should follow a process to assess the meaning of loss, the nature of the relationship, expressions and manifestations of grief, previous experience with grief, support systems, ability to maintain attachments, and progression of grief. Further, Arnold underscored the importance of viewing grief as a healing process (Table 27–3). She gave the following example of a patient situation and two different approaches to diagnosis:

A newly widowed woman feels awkward about maintaining social relationships with a group of married couples with whom she had participated with her husband.

- Grief as a pathological diagnosis: social isolation.
- Grief as a healthy diagnosis: redefinition of social supports.

### Table 27–3
Assessment of Grief

The bereaved often are weary from caring for the deceased. During this period they may not have looked after themselves. An assessment should include:

1. A general health checkup and assessment of somatic symptoms
2. A dental visit
3. An eye checkup as appropriate
4. Nutritional evaluation
5. Sleep assessment
6. Examination of ability to maintain work and family roles
7. Determination of whether there are major changes in presentation of self
8. Assessment of changes resulting from the death and the difficulties with these changes
9. Assessment of social networks

The health care worker needs to bear in mind that there is no magic formula for grieving. The key question is whether the bereaved is able to function effectively. Cues to the need for assistance include:

1. Clinical depression
2. Prolonged deep grief
3. Extreme grief reaction
4. Self-destructive behavior
5. Increased use of alcohol and/or drugs
6. Preoccupation with the deceased to the exclusion of others
7. Previous mental illness
8. Perceived lack of social support
In addition to conventional talking therapy, such techniques as letter writing, empty chair, guided imagery, and journal writing can be used (Table 27–4).\(^\text{81}\) In letter writing, the empty chair technique, and guided imagery, the bereaved is encouraged to express feelings about the past or what life is like without the deceased. These techniques can be helpful as the “wish I had said” becomes said. A journal is also a vehicle for recording ongoing feelings of the lived experience of bereavement.

Another part of bereavement counseling is the instillation or reemergence of hope. As Cutcliffe\(^\text{82}\) concluded, “There are many theories of bereavement counseling, with commonalities between these theories. Whilst the theories indicate implicitly the re-emergence of hope in the bereft individual as a result of the counseling, they do not make specific reference to how this inspiration occurs.” Cutcliffe saw the clear need to understand this process.

In her exposition of the concept “hope,” Stephenson\(^\text{83}\) noted the association made by Frankl\(^\text{84}\) between hope and meaning. Stephenson stated, “Frankl equated hope with having found meaning in life, and lack of hope as [having] no meaning in life.”\(^\text{85}\) Meaning-making appears key to the emergence of hope, and hope has been associated with coping.\(^\text{85}\)

In hospice programs, health care providers encourage dying persons and their families to have hope for each day. This compression of one’s vision to the here and now may also be useful for the person who is grieving the loss of a loved one. Hope for the future and a personal future is the process that Cutcliffe\(^\text{82}\) wished to elucidate. It may be a process that is predicated on hope for each day and having found meaning in the past. Sikkema and colleagues\(^\text{40}\) compared the effectiveness of individual and group approaches by evaluating individual psychotherapy and psychiatric services on demand with a support group format. The strategies employed in dealing with grief included establishing a sense of control and predictability, anger expression and management, resolution of guilt, promotion of self-mastery through empowerment, and development of new relationships. Those assigned to individual therapy may or may not have taken advantage of the option. Future research should examine three groups: those receiving individual counseling, those receiving group therapy, and those assigned no specific intervention but given information about various options for counseling and support in a pamphlet.

A therapist provides a vehicle for ongoing discussion of the loss that informal caregivers may be unable to provide. A support group of bereaved individuals or periodic contact by an institutional bereavement service may also prove useful. What is helpful depends on the individual and his or her needs and also on the informal support that is available.

**Informal Support**

Informal support that is perceived as supportive and helpful can assist the bereaved to come to terms with life after the death of the beloved. Whether the bereaved is isolated or is part of a family or social group is of tremendous import to the physical, psychological, and social welfare of the individual. Community in a psychosocial sense and a continuing role in the group are key factors in adjustment.

In societies where the widow has no role without her husband, she is figuratively if not literally disposed of in one way or another. It is for this reason that the woman who is the first in her group to experience widowhood has a much more difficult social experience than a woman who is in a social group where several women have become widows. In the former there is no reference group; in the latter there is.

The presence of family and friends takes on added significance after the initial weeks after the funeral. In those initial weeks, friendly visiting occurs with provision of a variety of types of foods considered appropriate in the group. After the initial period, friendly visiting is likely to decrease, and the bereaved individuals may find themselves alone or the objects of financial predators. The counsel by the health care provider or by family and friends, not to make life-altering decisions (e.g., moving) at this time unless absolutely necessary, continues to be valuable advice. On the other hand, the comment that “time makes it easier” is a half-truth that is not perceived as helpful by the bereaved.\(^\text{86,87}\)

What is helpful is being listened to by an interested person. Quinton\(^\text{87}\) disliked the term “counseling” in that implies the availability of a person with good counsel to confer. What Quinton considered important was “lots of listening to what the victim wants to off-load.” She observed, “The turning point for me was realizing that I had a right to feel sad, and to grieve and to feel miserable for as long as I felt the need.”\(^\text{87}\) By owning the grieving process, Quinton provided herself with the most important support for her recovery from a devastating experience—her mother’s murder in a massacre by the Irish Republican Army in 1987. The lesson is applicable, however, to any bereaved person regardless of whether the death was traumatic or anticipated. Quinton’s turning point is another clue to answering the question of the last section of this chapter: When is it over?

**When Is It Over?**

To use the colloquial phrase, it’s not over until it’s over. What does this mean? As long as life and memory persist, the deceased individual remains part of the consciousness of family and friends. When is the grieving over? Unfortunately, there is no easy answer and the only reasonable response, is “It depends.” Lindemann’s concept of grief work,\(^\text{47,48}\) mentioned earlier in this chapter, is applicable. Sooner or later that work needs to be accomplished. Delay protracts the time when accommodation is made. And grief work is never over, in the sense that there will be moments in years to come when an occasion or an object revives feelings of loss. The difference is that the pain is not the same acute pain as that experienced when the loss initially occurred. How one
Bereavement

Letting Go

The term “letting go” refers to acknowledgment of the loss of future togetherness—physical, psychological, and social. There is no longer a “we,” only an “I” or a “we” without the deceased. Family members speak of events such as the first time a flower or bush blooms, major holidays, birthdays, anniversaries, and special shared times. Corless quoted Jacqueline Kennedy, who spoke about “last year” (meaning 1962–1963) as the last time that her husband, John Kennedy, experienced a specific occasion:

On so many days—his birthday, an anniversary, watching his children running to the sea—I have thought, “but this day last year was his last to see that.” He was so full of love and life on all those days. He seems so vulnerable now, when you think that each one was a last time.

Mrs. Kennedy also wrote about the process of letting go, although she didn’t call it that:

Soon the final day will come around again—as inexorably as it did last year. But expected this time. It will find some of us different people than we were a year ago. Learning to accept what was unthinkable when he was alive changes you.

Finally, she addressed an essential truth of bereavement:

I don’t think there is any consolation. What was lost cannot be replaced.

Letting go encompasses recognizing the uniqueness of the individual. It also entails finding meaning in the relationship and experience. It does not mean cutting oneself off from memories of the deceased.

Continuing Bonds

Klass and associates\(^{57}\) contributed to the reformulation of thinking on the nature of accommodating to loss. Although theorists postulated that the grief process should be completed in 1 year, with one’s emotional energies once again invested in the living, the experience of the bereaved suggested otherwise. Bereaved persons visit the grave for periodic discussions with the deceased. They gaze at a picture and seek advice on various matters. Such behavior is not pathological. The provocative thesis that those with higher scores on the Continuing Bonds Scale experience elevated grief suggests not only an additional dimension to the grief process but that grief is the price that is exacted in the dissolution of close relationships.\(^{48}\)

It is a common expectation that teachers in the educational system will have an influence on their students. The students progress and may or may not have continuing contact with those educators. Given that assumption about education, how could we not expect to feel the continuing influence and memory of those informal teachers in our lives, our deceased family members and friends? Integration of those influences strengthens the individual at any point in his or her life.

A Turkish expression in the presence of death is, “May you live.”\(^{90}\) That indeed is the challenge of bereavement.

Family-Centered Palliative Care

Recognizing the importance of a family focus necessitates clearly defining what is meant by “family.” Most often, families in palliative care do consist of patients, their spouses, and their children. But in today’s world of divorce and remarriage, steprelatives must also enter into the family portrait. In other instances, people unrelated by blood or marriage may function as family. Therefore, the definition of family must be expanded. The family is a group of individuals inextricably linked in ways that are constantly interactive and mutually reinforcing. Family can mean direct blood relatives, relationships through an emotional commitment, or the group or person with which an individual feels most connected. Moreover, family in its fullest sense embraces all generations—past, present, future; those living, those dead, and those yet to be born. Shadows of the past and dreams of the future also contribute to the understanding of families.

Palliative care programs are based on the principle that the family is the unit of care. In practice, however, the family is often viewed as a group of individuals who can either prove helpful or resist efforts to deliver care. Nurses and other health professionals must strive to understand the meaning of the palliative experience to the family. If quality care is to be provided, nurses need to understand how all family members perceive their experience, how the relationships fit together, and that a multitude of factors combine to make families what they are. However, only recently has research gone beyond focusing on the needs of dying patients for comfort and palliation to addressing issues relevant to other family members. Much of this research has focused on the family’s perspective of their needs; experiences and challenges faced; adaptation and coping skills required for home care; the supportiveness of nursing behaviors or physician behaviors; and satisfaction with care. Most research has focused on families of patients with cancer, though recent reports extend to end-of-life care...
for other diagnostic populations, such as Parkinson’s disease,\textsuperscript{4} cardiac disease,\textsuperscript{5} and dementia.\textsuperscript{16} Findings make it clear that family members look to health professionals to provide quality care to the patient. Family members also expect health professionals to meet their own needs for information, emotional support, and assistance with care.\textsuperscript{14}

Much of the research that purports to address the impact of cancer on the family is based on the perceptions of individuals—either the patient or adult family members (usually the spouse). As well, many of the studies were conducted retrospectively, that is, after the patient’s death. But even studies conducted during the palliative period frequently exclude the patient—the one who is at the center of the palliative care situation. Examining the palliative experience of the family unit has been rare.

As a basis for offering optimal support to families in palliative care, this chapter focuses on describing the findings of a research program that prospectively examined the experiences of such families.\textsuperscript{17} The research evolved from nurses’ concerns about how to provide family-centered palliative care. Nurses in a regional cancer center constantly had to attend to the needs of not only patients but also patients’ families, particularly as they moved back and forth between hospital and home. In searching the literature for guidelines about family-centered care, they found that many articles were about the needs of patients and family members, about levels of family members’ satisfaction with care, and about family members’ perceptions of nurses, but nothing really described the families’ experiences as they coped with the terminal illness of a beloved family member. Research involving families included patients with advanced cancer, their spouses, and at least one of their adult children (>18 years of age). Since the completion of the original research, families with AIDS, Alzheimer’s disease, and cardiac disease have provided anecdotal validation of the findings for their experiences. In addition, families of children with progressive, life-threatening illness have provided similar validation. Therefore, it seems that the conceptualization has relevance for a wide range of families in palliative care. The findings from this research program form the basis for the description that follows; references to additional research studies are also included to supplement and emphasize the ongoing development of knowledge in the field of family-centered end-of-life care.

The Transition of Fading Away

The common view is that transitions are initiated by changes, by the start of something new. However, as Bridges\textsuperscript{18} suggests, most transitions actually begin with endings. This is true for families living with serious illness in a loved one. The nurses’ research findings generated a theoretical scheme that conceptualized families’ experiences as a transition—a transition that families themselves labeled as “fading away.” The transition of fading away for families facing terminal illness began with the ending of life as they knew it. They came to realize that the ill family member was no longer living with cancer but was now dying from cancer.

Despite the fact that family members had been told about the seriousness of the prognosis, often since the time of diagnosis, and had experienced the usual ups and downs associated with the illness trajectory, for many the “gut” realization that the patient’s death was inevitable occurred suddenly: “It struck me hard—it hit me like a bolt. Dad is not going to get better!” The awareness was triggered when family members saw, with “new eyes,” a change in the patient’s body or physical capacity, such as the patient’s weight loss, extreme weakness, lack of mobility, or diminished mental capacity. Realizing that the patient would not recover, family members began the transition of fading away. As one patient commented, “My body has shrunk so much—the other day, I tried on my favorite old blue dress and I could see then how much weight I have lost. I feel like a skeleton with skin! I am getting weaker. . . . I just can’t eat much now, I don’t want to. I can see that I am fading. . . . I am definitely fading away.”

The transition of fading away is characterized by seven dimensions: redefining, burdening, struggling with paradox, contending with change, searching for meaning, living day by day, and preparing for death. The dimensions do not occur in linear fashion; rather, they are interrelated and inextricably linked to one another. Redefining, however, plays a central role. All family members experience these dimensions, although patients, spouses, and children experience each dimension somewhat differently.

Redefining

Redefining involves a shift from “what used to be” to “what is now.” It demands adjustment in how individuals see themselves and each other. Patients maintained their usual patterns for as long as possible and then began to implement feasible alternatives once they realized that their capacities were seriously changing. Joe, a truck driver, altered his identity over time: “I just can’t do what I used to. I finally had to accept the fact that the seizures made it unsafe for me to drive.” Joe requested to help out at his company’s distribution desk. When he could no longer concentrate on keeping the orders straight, Joe offered to assist with supervising the light loading. One day, Joe was acutely aware he didn’t have the energy to even sit and watch the others: “I couldn’t do it anymore,” Joe sighed. “I had reached the end of my work life and the beginning of the end of my life.” Another patient, Cora, lamented that she used to drive to her son’s home to baby-sit her toddler-aged grandchildren; then her son dropped the children off at her house to preserve the energy it took for her to travel; and now, her son has made other child care arrangements. He brings the children for only short visits because of her extreme fatigue.

Both Joe and Cora, like the other patients, accepted their limitations with much sadness and a sense of great loss. Their focus narrowed, and they began to pay attention to details of
everyday life that they had previously ignored or overlooked. Joe commented, “When I first was at home, I wanted to keep in touch with the guys at the depot; I wanted to know what was going on. Now, I get a lot of good just watching the grandkids out there playing in the yard.”

Patients were eager to reinforce that they were still the same on the inside, although they acknowledged the drastic changes in their physical appearance. They often became more spiritual in their orientation to life and nature. As Joe said, “I always liked being outside—was never much of an office-type person. But, now, it seems I like it even more. That part of me hasn’t changed even though it’s hard for some of the fellas (at work) to recognize me now.” When patients were able to redefine themselves as Joe did, they made the best of their situation, differentiating what parts of them were still intact. Joe continued, “Yeah, I like just being outside, or watching the kids. And, you know, they still come to their Grandpa when their toy breaks down—I can pretty much always fix ‘em.” Similarly, Cora commented: “At least, I can still make cookies for when the trucks break down—I need a lot of practice, too.”

Patients shared their changing perceptions with family members and others, who then were able to offer understanding and support.

Patients who were unable to redefine themselves in this way attempted to maintain their regular patterns despite the obvious changes in their capacity to do so. They ended up frustrated, angry, and feeling worthless. These reactions distanced them from others, resulting in the patients’ feeling alone and, sometimes, abandoned. Ralph, for example, was an educational administrator. Despite his deteriorating health, he insisted that he was managing without difficulty. “Nothing’s wrong with me, really. We are being accredited this year. There’s a lot to do to get ready for that.” Ralph insisted on going into the office each day to prepare the necessary reports. His increasing confusion and inability to concentrate made his reports inaccurate and inadequate, but Ralph refused to acknowledge his limitations or delegate the work. Instead, his colleagues had to work overtime to correct Ralph’s work after he left the office. According to Ralph’s wife, anger and frustration were commonplace among his colleagues, but they were reluctant to discuss the issue with Ralph. Instead, they avoided conversations with Ralph, and he complained to his wife about his colleagues’ lack of interest in the project.

For the most part, spouses took the patient’s physical changes in stride. They attributed the changes to the disease, not to the patient personally, and as a result, they were able to empathize with the patient. Patients’ redefining focused on themselves, the changes in their physical status and intrapersonal aspects; spouses’ redefining centered on their relationship with the patient. Spouses did their best to “continue on as normal,” primarily for the sake of the patient. In doing so, they considered alternatives and reorganized their priorities.

Sherman described the “reciprocity of suffering” that family members experience, which results from the physical and emotional distress that is rooted in their anguish of dealing with the impending death of the loved one and in their attempt to fill new roles as caregivers. The degree to which family members experienced this phenomenon varied according to patients’ redefining. When patients were able to redefine themselves, spouses had an easier time. Such patients accepted spouses’ offers of support; patients and spouses were able to talk about the changes that were occurring. Spouses felt satisfied in the care that they provided. But when patients were less able to redefine, then spouses’ offers of support were rejected or unappreciated. For example, Ralph’s wife worried about his work pattern and its impact on his colleagues. She encouraged him to cut back, but Ralph only ignored her pleas and implied that she didn’t understand how important this accreditation was to the future of his school. Even when Ralph was no longer able to go to the office, he continued to work from home, frequently phoning his colleagues to supervise their progress on the report. His wife lamented, “For an educated man, he doesn’t know much. I guess it’s too late to teach an old dog new tricks.”

In such situations, spouses avoided talking about or doing anything that reminded the patient of the changes he or she was experiencing but not acknowledging. The relationship between the spouse and patient suffered. Rather than feeling satisfied with their care, spouses were frustrated and angry, although often they remained silent and simply “endured” the situation. The ill person contributed significantly to the caregiver’s ability to cope. Indeed, the ill person was not simply a passive recipient of care but had an impact on the experience of the caregiving spouse. Similarly, in their study of factors that influence family caregiving of persons with advanced cancer, Strang and Koop found that the ill person contributed significantly to the capacity of the spouse to continue to provide care despite their experience of overwhelming emotional and physical strain. Caregivers drew strength from the dying person when the ill person accepted the impending death, had an understanding of the caregivers’ needs, and had attitudes, values, and beliefs that sustained their caregivers.

Adult children also redefined the ill family member; they redefined their ill parent from someone who was strong and competent to someone who was increasingly frail. Children felt vulnerable in ways they had not previously experienced. Most often, children perceived that the changes in their ill parent were the result of disease and not intentional: “It’s not my father doing this consciously.” Younger adult children were particularly sensitive to keeping the situation private, claiming they wanted to protect the dignity of the patient, but seemed to want to protect their own sense of propriety. For example, one young woman in her early twenties was “devastated” when her father’s urinary bag dragged behind him as he left the living room where she and her friends were visiting. It was difficult for some young adults to accept such manifestations of their parent’s illness. Adolescents in particular had a difficult time redefining the situation. They preferred to continue on as if nothing was wrong and to shield themselves against any information that would force them to see the situation realistically.

When the ill parent was able to redefine to a greater degree, then children were better able to appreciate that death is part of life. They recognized their own susceptibility and vowed to
take better care of their own health; older children with families of their own committed to spending more quality time with their children. Joe talked, although indirectly, with his son about the situation: “I won’t be here forever to fix the kids’ toys.” Together, Joe and his son reminisced about how Joe had always been available to his son and grandchildren as “Mr. Fix-it.” Joe valued his dad’s active participation in his life and promised to be the same kind of father to his own sons. In contrast, when the ill parent was unable to redefine, then children tended to ignore the present. They attempted to recreate the past to construct happy memories they never had. In doing so, they often neglected their own families. Ralph’s daughter described her dad as a “workaholic.” Feeling as if she had never had enough time with her dad, she began visiting her parents daily, with suggestions of places she could take him. He only became annoyed with her unfamiliar, constant presence: “It’s okay she comes over every day, but enough is enough.”

The extent to which spouses and adult children commented on the important contribution made by the dying family member is a provocative finding that underscores the importance of relationships among and between family members in facilitating their coping with the situation of terminal illness.

Burdening

Feeling as if they are a burden for their family is common among patients. If patients see themselves as purposeless, dependent, and immobile, they have a greater sense of burdening their loved ones. The more realistically patients redefined themselves as their capacities diminished, the more accurate they were in their perceptions of burdening. They acknowledged other family members’ efforts, appreciated those efforts, and encouraged family members to rest and take time to care for themselves. Patients who were less able to redefine themselves did not see that they were burdening other family members in any way. They denied or minimized the strain on others. As Ralph said during the last week of his life, “I can’t do much, but I am fine really. Not much has changed. It’s a burden on my wife, but not much. It might be some extra work. . . . She was a nursing aide, so she is used to this kind of work.”

Most spouses acknowledged the “extra load” of caring for their dying partner, but indicated that they did not regard the situation as a “burden.” They agreed that it’s “just something you do for the one you love.” Spouses did not focus on their own difficulties; they managed to put aside their own distress so that it would not have a negative impact on their loved one. They sometimes shared stories of loneliness and helplessness, but also stories of deepening respect and love for their partner. Again, spouses of patients who were able to redefine were energized by the patient’s acknowledgment of their efforts and were inspired to continue on. Spouses of patients who were not able to redefine felt unappreciated, exhausted, and confessed to “waiting for the patient to die.”

The literature provides a comprehensive description of the multidimensional nature of the burden experienced by family caregivers, but no attention has been given to the burdening felt by patients or adult children specifically. Caregiver burden, usually by spouses, has been described in terms of physical burden, which includes fatigue and physical exhaustion, sleeplessness, and deterioration of health. Social burden encompasses limited time for self and social stress related to isolation. Regardless of the type of burden, however, most caregivers, including the ones in the fading away studies, expressed much satisfaction with their caregiving. Despite feeling burdened, most caregivers would repeat the experience: “Yes, it was difficult and exhausting, and there were days I didn’t think I could manage one more minute. But, if I had to do it over again, I would. I have no regrets for what I am doing.”

Children, too, experienced burdening, but the source stemmed from the extra responsibilities involved in helping to care for a dying parent superimposed on their work responsibilities, career development, and their own families. As a result, adult children of all ages felt a mixture of satisfaction and exhaustion. Their sense of burdening was also influenced by the ill parent’s redefining—if the ill parent acknowledged their efforts, they were more likely to feel satisfaction. However, children’s sense of burdening was also influenced by the state of health of the well parent. If that parent also was ill or debilitated, the burden on children was compounded. If children were able to prioritize their responsibilities so that they could pay attention to their own needs as well as helping both their parents, they felt less burdened. Children seemed less likely than their well parents to perceive caregiving as something they themselves would do. Of course, they did not have the life experience of a long-term relationship that motivated the spouses to care for their partners.

Finding effective ways to support family caregivers is critical, because an increase in the proportion of elderly people in the population means growing numbers of people with chronic, life-threatening, or serious illness require care. The responsibility for the care of such individuals is increasingly being placed on families. Respite care is often suggested as a strategy for relieving burden in family caregivers. One review was conducted of studies examining the effect of respite provision on caregivers. Surprisingly, the researchers found little evidence that respite provision had either a consistent or an enduring beneficial effect on caregivers’ well being. The authors offered two explanations: the studies were methodologically poor and respite care often failed to facilitate the development of socially supportive relationships to provide a moderating influence.

However, another potential factor influencing the success of respite care may be the dynamics within the family, in particular between the patient and family caregivers. Respite must be assessed in conjunction with the role of redefining in burdening. Support for this suggestion comes from a study, based in the Netherlands, of the experiences of caregivers, which showed that support from informal and professional caregivers was not sufficient to balance the stresses of caregiving and the missing element may be internal to the family. These findings encourage greater exploration into respite care and its meaning to caregivers. In one study of home-based
family caregiving, caregivers differentiated between cognitive and physical breaks.11 They valued cognitive breaks during which they remained within the caregiving environment, but physical separation from the caregiving environment was valuable only if it contributed in some meaningful way to the caregiving.

**Struggling with Paradox**

Struggling with paradox stems from the fact that the patient is both living and dying. For patients, the struggle focuses on wanting to believe they will survive and knowing that they will not. On “good days,” patients felt optimistic about the outcome; on other days, they succumbed to the inevitability of their approaching demise. Often, patients did not want to “give up” but at the same time were “tired of fighting.” They wanted to “continue on” for the sake of their families but also wanted “it to end soon” so their families could “get on with their lives.” Patients coped by hoping for miracles, fighting for the sake of their families, and focusing on the good days. As Joe said, “I like to think about the times when things are pretty good. I enjoy those days. But, on the bad days, when I’m tired, or when the pain gets the best of me, then I just wonder if it wouldn’t be best to just quit. But you never know—maybe I’ll be the one in a million who makes it at the last minute.” He then added wryly, “Hmm, big chance of that.”

Spouses struggled with a paradox of their own: they wanted to care for and spend time with the patient, and they also wanted a “normal” life. They coped by juggling their time as best they could, and usually put their own life on hold. Spouses who managed to find ways of tending to their own needs usually were less exhausted and reported fewer health problems than spouses who neglected their own needs. For years, Joe and his wife had been square dancers. They hadn’t been dancing together for many months when his wife resumed going to “dance night as a sub” or to prepare the evening’s refreshments. "Sometimes, I feel guilty for going and leaving Joe at home, but I know I need a break. When I did miss dance night, I could see I was getting really bitchy—I need to get out for a breather so I don’t suffocate Joe.”

Children struggled with hanging on and letting go to a greater extent than their parents. They wanted to spend time with their ill parent and also to “get on with their own lives.” Feeling the pressure of dual loyalties (to their parents and to their own young families), the demands of both compounded the struggle that children faced.

**Contending with Change**

Those facing terminal illness in a family member experience changes in every realm of daily life—relationships, roles, socialization, work patterns. The focus of the changes differed among family members. Patients faced changes in their relationships with everyone they knew. They realized that the greatest change of their life was underway and that life as they knew it would soon be gone. They tended to break down tasks into manageable pieces, and increasingly they focused inward. The greatest change that spouses faced was in their relationship with the patient. They coped by attempting to keep everything as normal as possible. Children contended with changes that were more all-encompassing. They could not withdraw as their ill parent did, nor could they prioritize their lives to the degree that their well parent could. They easily become exhausted. As Joe’s son explained, “It’s a real challenge coming by this often—I try to come twice a week and then bring the kids on the weekends. But I just got a promotion at work this year so that’s extra work too. Seems like I don’t see my wife much—but she’s a real trooper. Her dad died last year so she knows what it’s like.”

**Searching for Meaning**

Searching for meaning has to do with seeking answers to help in understanding the situation. Patients tended to journey inward, reflect on spiritual aspects, deepen their most important connections, and become closer to nature: “The spiritual thing has always been at the back of my mind, but it’s developing more. . . . When you’re sick like that, your attitude changes toward life. You come not to be afraid of death.”

Spouses concentrated on their relationship with the patient. Some searched for meaning through personal growth, whereas others searched for meaning by simply tolerating the situation. Some focused on spiritual growth, and others adhere rigidly to their religion with little, if any, sense of inner growth or insight. Joe’s wife commented, “Joe and I are closer than ever now. We don’t like this business, but we have learned to love each other even more than when we were younger—sickness is a hard lesson that way.” In contrast, Ralph’s wife said with resignation, “He’s so stubborn—always has been. I sometimes wonder why I stayed. But, here I am.” Spouses and patients may attribute different meanings to other aspects of their experience as well. For example, when seeing their loved one in pain, many spouses felt helpless and fearful. Once the pain was controlled, they felt peaceful and relaxed and interpreted this as an indication that the couple would return to their old routines. The patient’s meaning of the experience, however, often focused on future consequences of the pain.6 The meaning attributed to the patient’s experience also influenced spousal bereavement. For example, spouses who witnessed the patient die a painful death and who believed that physician negligence was the cause of the pain experience elevated anger and much distress after the death.27

Children tended to reflect on and reevaluate all aspects of their lives: “It puts in perspective how important some of our goals are. . . . Having financial independence and being able to retire at a decent age. . . . Those things are important, but not at the expense of sacrificing today.”

**Living Day to Day**

Not all families reached the point of living day to day. If patients were able to find some meaning in their experience,
then they were better able to adopt an attitude of living each day. Their attitude was characterized by “making the most of it.” As one patient described it, “There’s not much point in going over things in the past; not much point in projecting yourself too far into the future either. It’s the current time that counts.” Patients who were unable to find much meaning in their experience, or who didn’t search for meaning, focused more on “getting through it.” As Ralph said with determination, “Sure, I am getting weaker. I know I am sick. . . . But I will get through this!” Spouses who searched for meaning focused on “making the best of it” while making every effort to enjoy the time they had left with their partner. Other spouses simply endured the situation without paying much attention to philosophizing about the experience. Children often had difficulty concentrating on living day to day, because they were unable to defer their obligations and therefore were constantly worrying about what else needed to be done. However, some children were still able to convey an attitude of “Live for today, today—worry about tomorrow, tomorrow.”

Preparing for Death

Preparing for death involved concrete actions that would have benefit in the future, after the patient died. Patients had their family’s needs uppermost in their minds and worked hard to teach or guide family members with regard to various tasks and activities that the patient would no longer be around to do. Patients were committed to leaving legacies for their loved ones, not only as a means of being remembered, but also as a way of comforting loved ones in their grief. Joe spent time “jotting down a few Mr. Fix-it pointers” for his wife and son. Ralph’s energy was consumed by focusing on the work he still had to do, so he was unable to consider what he might do for his wife and daughter.

Spouses concentrated on meeting the patient’s wishes. Whatever the patient wanted, spouses would try to do. They attended to practical details and anticipated their future in practical ways. Children offered considerable help to their parents with legal and financial matters. They also prepared their own children for what was to come. A central aspect was reassuring the dying parent that they would take care of the surviving parent. Children also prepared for the death by envisioning their future without their parent: “I think about it sometimes, . . . about how my children will never have a grandfather. It makes me so sad. That’s why the photos we have been taking are so important to me. . . . They will show our children who their grandfather was.”

Palliative Care for Diagnoses Other Than Cancer

Traditionally, palliative care practice and discussions have focused on families of cancer patients. At the same time, care of the patient with cardiac disease, for example, has traditionally focused on restoring health and enabling a return to normal life. So, the idea of providing a patient with aggressive versus palliative treatment has, until recently, not been a well-discussed issue in the treatment of the patient with heart disease. For most patients with heart disease, and particularly for those with heart failure, the decline in functional status is slower than for patients diagnosed with cancer. However, if palliative care is considered only after disease-related care fails or becomes too burdensome, the opportunity for patients to achieve symptom relief and for patients and family members to engage in the process of fading away may be lost. Consequently, following a model of care wherein issues of treatment and end-of-life care are discussed early and throughout the illness trajectory facilitates patient and family coping and enables nurses to optimally support families.

Varying disease trajectories for other conditions, such as dementia, also influence the nature of support that nurses provide patients and families. For example, in a comparative study of staff’s assessment of support needed by families of dementia and cancer patients, staff in dementia care stressed significantly more the need for forming support groups for families, offering respite care, educating families, and trying to relieve families’ feeling of guilt. In the cancer care group, staff assigned greater importance to being available to listen, creating a sense of security, and supporting the family after death.

Family Involvement According to Location of Care

Over the past century, nursing homes and hospitals increasingly have become the site of death. A recent national study evaluated the U.S. dying experience at home and in institutional settings. Family members of 1578 deceased individuals were asked via telephone survey about the patient’s experience at the last place of care at which the patient spent >48 hours. Results showed that two thirds (67.2%) of patients were last cared for in an institution. Family members reported greater satisfaction with patient’s symptom management and with emotional support for both the patient and family if they received care at home with hospice services. Families have greater opportunities for involvement in the care if home care is possible. Family involvement in hospital care also makes for better outcomes. Among geriatric patients receiving end-of-life care in a hospital setting, family involvement before death reduces the use of technology and increases the use of comfort care as patients die. Nurses, therefore, must consider how best to include families in the care of their dying loved ones, regardless of the location of care.

Large variations exist in the provision of home-based palliative and terminal care across the United States, although the development of hospice home services has enabled increasing numbers of seriously ill patients to experience care at home. However, dying at home can present special challenges for family members. Lack of support and lack of confidence have
been found to be determinants contributing to hospital admissions and the breakdown of informal caregiving for people with a life-threatening illness. A lack of support from the health care system is given as the reason many caregivers have to admit their loved one to the hospital. They also report that fragmentation of services and lack of forward planning jeopardizes the success of home care.

Moreover, the decision for home care has a profound effect on family members. In an ethnographic study investigating palliative care at home, caregiver decisions for home care were characterized in three ways. Some caregivers made uninformed decisions, giving little consideration to the implications of their decision: “I made the decision just like that. . . . There wasn’t much thought that went into it.” Such decisions were made early in the patient’s disease trajectory or when the patient was imminently dying, and they were often influenced by the unrealistic portrayal in the media about dying at home. Indifferent decisions occurred if caregivers felt they had little choice. The patient’s needs and wishes often drove decisions, with caregivers paying little attention to their own needs. Negotiated decisions for home care typically occurred if caregivers and patients were able to talk openly about dying and had done so throughout the disease trajectory.

Family members’ decisions were influenced by three major factors: making promises to care for the loved one at home, the desire to maintain as much as possible a “normal” life for the patient and themselves, and negative experiences with institutional care. Of interest, family members did not think of themselves as the target of professional interventions. They were reluctant to ask for help or to let their needs be known. Consequently, when working with caregiving families, health care providers could mediate discussions with the aim of coming to a mutually acceptable decision about home care. Such discussions could allow the sharing of perspectives to allow for decisions that would work well for all concerned. Ideally, such discussions should begin early in the disease trajectory.

Importantly, ongoing attention should be paid to improving hospital end-of-life care so that families feel they have a meaningful alternative to home care. A small scale study to develop and evaluate care pathways for the last days of life in a community setting was developed and tested in the United Kingdom, based on the pioneering work of Ellershaw. The plan outlines the expected course of a patient’s trajectory; brings together all the anticipated aspects of care, particularly with regard to symptom management and caregiver support; and encourages forward planning to avoid crisis admission to the hospital. It serves as a model for how home care can be optimally delivered to those with terminal illness, echoing Doyle’s observation that good palliative care is an exercise in anticipation.

Clinicians must recognize the emotional impact of providing palliative care at home and must be sensitive to the sometimes overwhelming task that caregiving imposes on family caregivers. Acknowledging that availability and access to service is important, Stajduhar and Davies specified that care must be provided within a team context so that families can benefit from a whole set of services needed to support death at home. Clinicians must work with the dying patients, with family caregivers, and with each other as equal partners in the caregiving process.

Clinicians must be available to families, offering anticipatory guidance and support throughout the caregiving experience. Health care professionals must assist family members as they traverse the maze of treatment and care decisions, ranging from whether to give particular “as needed” medications, or what food to make for the patient to eat, to whether or not to seek hospice care, to sign “do-not-resuscitate” documents, or to terminate treatment. It is critical that palliative care professionals continually engage with caregivers in forward planning, interpretation, and monitoring of the inevitable decline and dying process of the ill person, so as to facilitate the feeling in caregivers that they are secure and supported in their physically and emotionally exhausting work. Families need to know whom to call and when, and how to reach them.

Some simple guidelines for families can serve to encourage their coping. For example, caregivers should be told to keep a small notebook handy for jotting down questions and answers. The pages may be divided in half lengthwise, using the column on the left for questions and the other column for answers. On the left-sider page may be used for questions and the opposite page for the answers. They should be advised to have the notebook with them whenever they talk with a member of the palliative care team. Family members should be reassured that nothing is trivial. All questions are important, and all observations are valuable. They should be encouraged to say when they do not understand something, and to ask for information to be repeated as necessary. Palliative care professionals can help by spelling words that family members do not understand or by jotting down explanations. They should reassure family members that asking for help is not a sign of failure, but rather a sign of good common sense. Following such simple guidelines helps keep families from feeling overwhelmed. And, if they do feel “out of control,” such guidelines, simple as they may seem, give family members some concrete action they can take to help with whatever the situation may be.

Clinicians must also remember that their own attitudes are critical; if families feel they are a “nuisance” to health care providers, they tend to be more anxious and to shy away from asking for help. Furthermore, clinicians are in ideal positions to advocate with politicians and policy makers to expand resources for home-based palliative care programs so that families can adequately and humanely be supported in their caregiving work.

Guidelines for Nursing Interventions

Much of the nursing literature, which provides guidelines for nursing care, addresses the importance of four major interventions that have relevance for all members of the palliative care team:

1. **Maintain hope** in patients and their family members. As families pass through the illness trajectory, the
nature of their hope changes from hope for cure, to hope for remission, to hope for comfort, to hope for a good death. Offering hope during fading away can be as simple as reassuring families that everything will be done to ensure the patient’s comfort. Talking about the past also can help some families by reaffirming the good times spent together and the ongoing connections that will continue among family members. Referring to the future beyond the immediate suffering and emotional pain can also sustain hope. For example, when adult children reassure the ill parent that they will care for the other parent, the patient is hopeful that the surviving spouse will be all right.

2. **Involve families** in all aspects of care. Include them in decision-making, and encourage active participation in the physical care of the patient. This is their life—they have the right to control it as they will. Involvement is especially important for children when a family member is very ill. The more children are involved in care during the terminal phase, and in the activities that follow the death, the better able they are to cope with bereavement.42

3. **Offer information.** Tell families about what is happening in straightforward terms and about what they can expect to happen, particularly about the patient’s condition and the process their loved one is to undergo. Doing so also provides families with a sense of control. Initiate the discussion of relevant issues that family members themselves may hesitate to mention. For example, the nurse might say, “Many family members feel as if they are being pulled in two or more directions when a loved one is very ill. They want to spend as much time as possible with the patient, but they also feel the pull of their own daily lives, careers, or families. How does this fit with your experience?”

4. **Communicate openly.** Open and honest communication with nurses and other health professionals is frequently the most important need of families. They need to be informed; they need opportunities to ask questions and to have their questions answered in terms that they can comprehend. Open communication among team members is basic to open communication with the families.

It is not an easy task for families to give up their comfortable and established views of themselves as death approaches. The challenge for members of the health care team is to help family members anticipate what lies ahead without violating their need to relinquish old orientations and hopes at a pace they can handle. These four broad interventions assist health care providers in providing good palliative care; the following guidelines offer further direction. They are derived from the direct accounts of patients, spouses, and children about the strategies they used to cope with the dimensions of fading away.

**Redefining**

Supporting patients and other family members with redefining requires that health care providers appreciate how difficult it is for family members to relinquish familiar perceptions of themselves and adopt unfamiliar, unwelcome, and unasked for changes into their self-perceptions. Disengagement from former perceptions and the adoption of new orientations occur over time. Nurses and other care providers are challenged to help family members anticipate and prepare for what lies ahead, while not pushing them at a pace that threatens their sense of integrity. Each family member redefines his or her own pace; interventions must be tailored according to the individual needs of each. At the same time, health care providers must support the family as a unit by reassuring family members that their varying coping responses and strategies are to be expected.

Provide opportunities for patients to talk about the losses incurred due to the illness, the enforced changes, the adaptations they have made, and their feelings associated with these changes. Reinforce their normal patterns of living as long as possible and as appropriate. When they can no longer function as they once did, focus on what patients still can do, reinforcing those aspects of self that remain intact. Acknowledge that roles and responsibilities may be expressed in new and different ways and suggest new activities appropriate to the patient’s interest and current capabilities.

The focus with spouses and children centers on explaining how the disease or treatment contributes to changes in the patient physically, psychologically, and socially. Provide opportunities for spouses to talk about how changes in the patient affect their marital relationship. Help children appreciate their parent from another perspective, such as in recalling favorite memories or identifying the legacies left. Discuss how they can face their own vulnerability by channeling concerns into positive steps for self-care. Reinforce the spouses’ and children’s usual patterns of living for as long as possible and as appropriate; when former patterns are no longer feasible, consider adjustments or alternatives.

Provide opportunities for spouses to discuss how they may reorganize priorities in order to be with and care for the patient to the degree they desire. Consider resources that enable the spouse to do this, such as the assistance of volunteers, home support services, or additional nursing services. Teach caregiving techniques if the spouse shows interest. With the children, discuss the degree to which they want to be open or private about the patient’s illness with those outside the family. Acknowledge that family members will vary in their ability to assimilate changes in the patient and in their family life.
Burdening

Palliative care professionals can help patients find ways to relieve their sense of burden and can provide patients with opportunities to talk about their fears and concerns and to consider with whom they want to share their worries. In this way, patients may alleviate their concern for putting excessive demands on family members. Explain the importance of a break for family members and suggest that patients accept assistance from a volunteer or home support services at those times to relieve family members from worry. Explain that when patients affirm family members for their efforts, this contributes to family members' feeling appreciated and reduces their sense of burden.

Nurses and all members of the interdisciplinary team can assist spouses with burdening by supporting the spouse's reassurances to the patient that he or she is not a burden. Acknowledge spouses' efforts when they put their own needs on hold to care for the patient; help them to appreciate the importance of taking care of themselves as a legitimate way of sustaining the energy they need for the patient. Talk with spouses about how they might take time out, and consider the various resources they might use. Acknowledge the negative feelings spouses may have about how long they can continue; do not negate their positive desire to help.

For children, acknowledge the reorganization and the considerable adjustment in their daily routines. Explain that ambivalent feelings are common—the positive feelings associated with helping and the negative feelings associated with less time spent on careers and their own families. Acknowledge that communicating regularly with their parents by telephoning or visiting often is part of the “work” of caring; the extra effort involved should not be underestimated. Encourage children to take time out for themselves, and support them in their desire to maintain involvement in their typical lives.

Struggling with Paradox

Facing the usual business of living and directly dealing with dying is a considerable challenge for all members of the family. The care provider's challenge is to appreciate that it is not possible to alleviate completely the family's psychosocial and spiritual pain. Team members must face their own comfort level in working with families who are facing paradoxical situations and the associated ambivalent feelings. Like family members, nurses, social workers, physicians, and all team members may also sometimes want to avoid the distress of struggling with paradox. They may feel unprepared to handle conversations in which no simple solution exists and strong feelings abound.

Care providers can support patients and other family members by providing opportunities for all family members to ventilate their frustrations and not minimizing their pain and anguish. On the good days, rejoice with them. Listen to their expressions of ambivalence, and be prepared for the ups and downs and changes of opinion that are sure to occur. Reassure them that their ambivalence is a common response. Encourage “time out” as a way to replenish depleted energy.

Contending with Change

Palliative care team members must realize that not all families communicate openly or work easily together in solving problems. Nurses in particular can support patients and family members to contend with change by creating an environment in which families explore and manage their own concerns and feelings according to their particular coping style. Providing information so that families can explore various alternatives helps them to determine what adjustments they can make. Make information available not only verbally but also in writing. Or, tape-record informative discussions so that families can revisit what they have been told.

Rituals can be helpful during periods of terminal illness. A family ritual is a behavior or action that reflects some symbolic meaning for all members of the family and is part of their collective experience. A ritual does not have to be religious in nature. Rituals may already exist, or they can be newly created to assist the family in contending with change. For example, the writing of an “ethical will,” whereby one passes on wisdom to others or elaborates on his or her hopes for their loved ones' future, can help ill family members communicate what they might not be able to verbalize to their loved ones. Developing new rituals can help with the changes in everyday life; for example, one woman had always been the sounding board for her children on their return from school. It was a pattern that continued as her children entered the work force. Cancer of the trachea prevented her participation in the same way. Instead, she requested her young adult children to sit by her side, hold her hand, and recount their days. Instead of words, the mother responded with varying hand squeezes to let them know she was listening. The altered daily ritual served both mother and children in adapting to the changes in their lives.

Searching for Meaning

Palliative care professionals help families search for meaning by enabling them to tell their personal story and make sense of it. It is essential that team members appreciate the value of storytelling—when families talk about their current situation and recollections of the past, it is not just idle chatter. It is a vital part of making sense of the situation and coping with it. Professional team members must appreciate that much of searching for meaning involves examining spiritual dimensions, belief systems, values, and relationships within and outside the family. Nurses can be supportive by suggesting approaches for personal reflection, such as journal writing or writing letters.

Living Day to Day

In living day to day, families make subtle shifts in their orientation to living with a dying family member. They move from
thinking that there is no future to making the most of the time they have left. This is a good time to review the resources available to the family, to ensure that they are using all possible sources of assistance so that their time together is optimally spent.

Preparing for Death

In helping families prepare for death, nurses in particular must be comfortable talking about the inevitability of death, describing the dying process, and helping families make plans for wills and funerals. It is important not to push or force such issues; it is equally important not to avoid them because of the nurse's personal discomfort with dying and death. Encourage such discussions among family members while acknowledging how difficult they can be. Affirm them for their courage to face these difficult issues. Encourage patients to attend to practical details, such as finalizing a will and distributing possessions. Encourage them to do "last things," such as participating in a special holiday celebration.

Provide information to spouses and children about the dying process. If the plan is for death at home, provide information about what procedures will need to be followed and the resources that are available. Provide opportunities for family members to express their concerns and ask questions. Encourage them to reminisce with the patient as a way of saying "good-bye" and acknowledge the bittersweet quality of such remembrances. Provide information to the adult children about how they can help their own children with the impending death.

The foregoing guidelines are intended to assist nurses and all members of the palliative care team in their care of individual family members. The guidelines are summarized in Table 28–1. In addition, family-centered care also means focusing on

Supporting Families in Palliative Care

555

the family as a unit. Health care providers must appreciate that
the family as a whole has a life of its own that is distinct but
always connected to the individuals who are part of it. Both
levels of care are important. The families in the “fading
away” study also provided insights about how family function-
ing plays a role in coping with terminal illness in a family
member.

Family Functioning and Fading Away

Families experienced the transition of fading away with
greater or lesser difficulty, depending on their level of func-
tioning according to eight dimensions: integrating the past,
dealing with feelings, solving problems, utilizing resources, con-
sidering others, portraying family identity, fulfilling roles, and
tolerating differences. These dimensions occurred along a con-
tinuum of functionality; family interactions tended to vary along
this continuum rather than being positive or negative, good
or bad.

Some families acknowledged the pain of past experience
with illness, loss, and other adversity and integrated previous
learning into how they were managing their current situation.
These families expressed a range of feelings, from happiness and
satisfaction, through uncertainty and dread, to sadness and sorrow.
Family members acknowledged their vulnerabili-
ties and their ambivalent feelings. All topics were open for dis-
cussion. There were no clearcut rights and wrongs, and no
absolute answers to the family’s problems. They applied a flex-
ible approach to problem-solving and openly exchanged all
information. They engaged in mutual decision-making, consider-
ing each member’s point of view and feelings. Each fam-
ily member was permitted to voice both positive and negative
opinions in the process of making decisions. They agreed on
the characteristics of their family and allowed individual vari-
ation within the family. They allocated household and patient
care responsibilities in a flexible way. These families were often

amenable to outside intervention and were comfortable in seeking and using external resources. Such families were often appealing to palliative care nurses and other personnel, because they openly discussed their situation, shared their concerns, and accepted help willingly.

Other families were more challenging for palliative care professionals. These were families who hung on to negative past experiences and continued to dwell on the painful feelings associated with past events. They appeared to avoid the feelings of turmoil and ambivalence, shielding themselves from the pain, often indicating that they did not usually express their feelings. These families approached problems by focusing more on why the problem occurred and who was at fault rather than generating potential solutions. They often were unable to communicate their needs or expectations to each other or to health care professionals and were angry when their wishes were not fulfilled. They expressed discrepant views only in individual interviews, not when all members were present, and tended not to tolerate differences. Varying approaches by health care workers were not generally well tolerated either. These families did not adapt easily to new roles, nor did they welcome outside assistance. Such families showed little concern for others. They used few resources, because family members were often unable or reluctant to seek help from others. Such families often presented a challenge for nursing care. Nurses must realize expecting such families to “pull together” to cope with the stresses of palliative care is unrealistic. It is essential not to judge these families, but rather to appreciate that the family is coping as best it can under very difficult circumstances. These families need support and affirmation of their existing coping strategies, not judgmental criticisms.

Palliative care clinicians are encouraged to complete assessments of level of family system functioning early in their encounters with families.43,44 This is the best time to begin to develop an understanding of the family as a whole, as a basis for the services to be offered. In fact, the value of focusing on patterns of family functioning has been demonstrated by a clinical approach that screens for families, rather than individuals, at high risk.45 Assessment of family functioning provides a basis for effective interactions to ensure a family-focused approach in palliative care. The eight dimensions of family functioning provide a guideline for assessment. Table 28–2 summarizes these dimensions and gives examples of the range of behaviors evident in each dimension. The table summarizes those behaviors that on one end of the continuum are more helpful, and on the other end are less helpful to families facing the transition of fading away.

Understanding the concept of family functioning enhances the nurse’s ability to assess the unique characteristics of each family. An assessment of family functioning enables the nurse to interact appropriately with the family and help them solve problems more effectively (Table 28–3). For example, in families where communication is open and shared among all members, the nurse can be confident that communication with one family member will be accurately passed on to other members. In families where communication is not as open, the nurse must take extra time to share the information with all members. Or, in families who dwell on their negative past experiences with the health care system, nurses must realize that the establishing trust is likely to require extra effort and time. Families who are open to outside intervention are more likely to benefit from resource referrals; other families may need more encouragement and time to open their doors to external assistance.

Nurses, and all palliative care providers, must remember that each family is unique and comes with its own life story and circumstances; listening to their story is central to understanding the family. There may be threads of commonality, but there will not be duplicate experiences. Nurses must assist family members to recognize the essential role they are playing in the experience and to acknowledge their contributions. Most importantly, nurses must realize that each family is doing the best it can. Nurses must sensitively, creatively, and patiently support families as they encounter one of the greatest challenges families must face—the transition of fading away.

Table 28–3
Family Functioning: Guidelines for Interventions in Palliative Care

<table>
<thead>
<tr>
<th>Assessing Family Functioning</th>
<th>Solving Problems</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use dimensions of family functioning to assess families. For example: Do members focus their concerns on the patient’s well-being and recognize the effect of the situation on other family members, or do family members focus their concerns on their own individual needs and minimize how others might be affected? Putting your assessment of all the dimensions together will help you determine to what degree you are dealing with a more cohesive family unit or a more loosely coupled group of individuals, and hence what approaches are most appropriate.</td>
<td>Use your assessment of family functioning to guide your approaches. For example, in families where there is little consensus about the problems, rigidity in beliefs, and inflexibility in roles and relationships, the common rule of thumb—offering families various options so they may choose those that suit them best—tends to be less successful. For these families, carefully consider which resource provides the best possible fit for that particular family. Offer resources slowly, perhaps one at a time. Focus considerable attention on the degree of disruption associated with the introduction of the resource, and prepare the family for the change that ensues. Otherwise, the family may reject the resource as unsuitable and perceive the experience as yet another example of failure of the health care system to meet their needs.</td>
</tr>
<tr>
<td>Be prepared to collect information over time and from different family members. Some family members may not be willing to reveal their true feelings until they have developed trust. Others may be reluctant to share differing viewpoints in the presence of one another. In some families, certain individuals take on the role of spokesperson for the family. Assessing whether everyone in the family shares the viewpoints of the spokesperson, or whether different family members have divergent opinions but are reluctant to share them, is a critical part of the assessment.</td>
<td>Be aware of the limitations of family conferences and be prepared to follow up. Family conferences work well for more cohesive family units. However, where more disparity exists among the members, they may not follow through with the decisions made, even though consensus was apparently achieved. Though not voicing their disagreement, some family members may not be committed to the solution put forward and may disregard the agreed-upon plan. The nurse needs to follow up to ensure that any trouble spots are addressed.</td>
</tr>
<tr>
<td>Listen to the family’s story and use clinical judgment to determine where intervention is required. Part of understanding a family is listening to their story. In some families, the stories tend to be repeated and the feelings associated with them resurface. Talking about the past is a way of being for some families. It is important that the nurse determine whether family members are repeatedly telling their story because they want to be better understood or because they want help to change the way their family deals with the situation. Most often the stories are retold simply because family members want the nurse to understand them and their situation better, not because they are looking for help to change the way their family functions.</td>
<td>Be prepared to repeat information. In less-cohesive families, do not assume that information will be accurately and openly shared with other family members. You may have to repeat information several times to different family members and repeat answers to the same questions from various family members.</td>
</tr>
<tr>
<td>Evaluate the appropriateness of support groups. Support groups can be a valuable resource. They help by providing people with the opportunity to hear the perspectives of others in similar situations. However, some family members need more individualized attention than a support group provides. They do not benefit from hearing how others have experienced the situation and dealt with the problems. They need one-to-one interaction focused on themselves with someone with whom they have developed trust.</td>
<td>Adjust care to the level of family functioning. Some families are more overwhelmed by the palliative care experience than others. Understanding family functioning can help nurses appreciate that expectations for some families to “pull together” to cope with the stress of palliative care may be unrealistic. Nurses need to adjust their care according to the family’s way of functioning and be prepared for the fact that working with some families is more demanding and the outcomes achieved are less optimal.</td>

REFERENCES

Planning for the Actual Death

There is a sweetness to being there when someone dies, as I was with my father. I held his hand as he died and will never forget how warm his hand was, even after he was gone. The veil between this life and the next, I believe, is thin. I sensed his spirit leave his body but it remained in the room long after he had died, as if he was trying to say to me, “Marsha, it was my time and I am now in a better place.” As an obstetrics nurse, I have witnessed many births but few deaths, but am struck by the similarities between them. Birth and death—the beginnings and endings we all experience as humans—are indeed sacred events.—A daughter

Key Points

- The care of patients and families near to death and afterward is an important nursing function—arguably one of the most important. There are often no dress rehearsals; nurses and other health care professionals often only have one chance to “get it right.”
- Aggressive management of symptoms remains a priority as death approaches.
- As the dying person nears death, the goals of care often change with patient and family needs, desires, and perspectives, providing a different experience for everyone.
- Care of the body after death, including honoring rituals and individual requests, can clearly communicate to the family that the person who died was indeed important and valued.

Issues and needs at the time of death are exceedingly important and, at the same time, exceedingly personal. Although the physiology of dying may be the same for most expected deaths, the psychological, spiritual, cultural, and family issues are as unique and varied as the patients and families themselves. As death nears, the goals of care must be discussed and appropriately redefined. Some treatments may be discontinued, and symptoms may intensify, subside, or even appear anew. Physiological changes as death approaches must also be defined, explained, and interpreted to the patient, whenever possible, as well as to the patient’s family, close others, and caregivers. The nurse occupies a key position in assisting patients’ family members at the time of death by supporting or suggesting death rituals, caring for the body after death, and facilitating early grief work. Most of the focus on death and dying in the past has been on dying in general, making the need for a chapter focused specifically on the actual death even more important.

Terminally ill persons are cared for in a variety of settings, including home settings with hospice care or traditional home care, hospice residential facilities, nursing homes, assisted living facilities, hospitals, intensive care units, prisons, and group homes. Deaths in intensive care settings may present special challenges, such as restrictive visiting hours and lack of space and less privacy for families—shortcomings that may be addressed by thoughtful and creative nursing care. Likewise, death in a nursing home setting may also offer unique challenges. Regardless of the setting, good management can minimize distressing symptoms and maximize quality of life. Families can be supported in a way that optimizes use of valuable time and lessens distress during the bereavement period. Like it or not, health professionals only have one chance to “get it right” when caring for dying persons and their families as death nears. In other words, there is no dress rehearsal for the time surrounding death; extensive planning ensures the least stressful and best possible outcome for all involved.

The patient’s family is especially important as death nears. Family members may become full- or part-time caregivers;
daughters and sons may find themselves in a position to “parent” their parents; and family issues, long forgotten or ignored, may surface. Although “family” is often thought of in traditional terms, a family may take on several forms and configurations. For purposes of this chapter, the definition of family recognizes that many patients have nontraditional families and may be cared for by a large extended entity, such as a church community, a group of supportive friends, or the staff of a health care facility. Family is defined broadly to include not only persons bound by biology or legal ties but also those whom the patient defines or who define themselves as “close others” or who function for the patient in “familistic” ways. These functions can include nurturance; intimacy; economic, social, and psychological support in times of need; support in illness (including dealing with those outside the family); and companionship.1,2

The research regarding uncontrolled symptoms at the end of life is misleading. It is most often performed in palliative care units or other settings dedicated to end-of-life care, in which the goals of care are focused on ensuring maximal symptom management. However, most studies demonstrate that the majority of people do not have a death in which symptoms are well managed.3,4 Up to 52% of persons have refractory symptoms at the very end of life that, at times, require terminal sedation.3 Dyspnea may worsen as death approaches. The notion of a final crescendo of pain is supported in some studies and not in others. Many patients experience a higher frequency of noisy and moist breathing, urinary incontinence and retention, restlessness, agitation, delirium, and nausea and vomiting.6,7 Less frequently, symptoms such as sweating, myoclonus, and confusion have been reported.6

Ventafridda and colleagues8 reported that, although most patients (91.5%) die peacefully, 8.5% experience symptoms requiring additional intervention in the final 24 hours, such as hemorrhage or hemoptysis (2%), respiratory distress (2%), restlessness (1.5%), pain (1%), myocardial infarction (1%), and regurgitation (1%). The wide variation in frequency of symptoms and reported “good deaths” may result from differing populations and sites of care (e.g., home, specialized palliative care unit, inpatient hospice), differing measurement protocols or instruments, and the participants’ cultural variations in reporting symptoms and approaching death. In most studies, symptoms requiring maximum diligence in assessment, prevention, and aggressive treatment during the final day or two before death were respiratory tract secretions, pain, dyspnea, restlessness, and agitation.7,9 Some authors emphasized that persons with cognitive impairment require specific attention to symptoms, especially as death nears.9 The nurse plays a key role in educating family members and other caregivers about the assessment, treatment, and continual evaluation of these symptoms.

Regardless of individual patient and family needs, attitudes, and “unfinished business,” the nurse’s professional approach and demeanor at the time near death is crucial and worthy of close attention. Patients experience total and profound dependency at this stage of their illness. Families are often called upon to assume total caregiving duties, often disrupting their own responsibilities for home, children, and career. Although there may be similarities, patients and families experience this time through the lens of their own perspective and form their own unique meaning.

Some authors suggest theories and guidelines as the basis for establishing and maintaining meaningful, helpful, and therapeutic relationships with patients or clients and their families. One example is Carl Rogers’ theory of helping relationships, in which he proposed that the characteristics of a helping relationship are empathy, unconditional positive regard, and genuineness.10 These characteristics, defined later as part of the nurse’s approach to patients and families, are essential in facilitating care at the end of life. To this may be added “attention to detail,” because this additional characteristic is essential for quality palliative care.11,12 Readers are urged to consider the following characteristics in the context of their own practices, as a basis for facilitating and providing supportive relationships:

- **Empathy:** the ability to put oneself in the other person’s place, trying to understand the patient or client from his or her own frame of reference; it also requires the deliberate setting aside of one’s own frame of reference and bias.
- **Unconditional positive regard:** a warm feeling toward others, with a nonjudgmental acceptance of all they reveal themselves to be; the ability to convey a sense of respect and esteem at a time and place in which it is particularly important to do so.
- **Genuineness:** the ability to convey trustworthiness and openness that is real rather than a professional facade; also the ability to admit that one has limitations, makes mistakes, and does not have all the answers.
- **Attention to detail:** the learned and practiced ability to think critically about a situation and not make assumptions. The nurse, for example, discusses challenging patient and family concerns with colleagues and other members of the interdisciplinary team. The nurse considers every “what if” before making a decision and, in particular, before making any judgment. Finally, the nurse is constantly aware of how his or her actions, attitudes, and words may be interpreted—or misinterpreted—by others.11

The events and interactions—positive as well as negative—at the bedside of a dying person set the tone for the patient’s care and form lasting memories for family members. The time of death and the care received by both the individual who has died and the family members who are present are predominant aspects of the survivors’ memories of this momentous event.13 Approaching patients and families with a genuine openness characterized by empathy and positive regard eases the
way in making this difficult time meaningful, individualized, and deeply profound.

This chapter discusses some key issues surrounding the death itself, including advanced planning, the changing focus of care as death nears, common signs and symptoms of death and their management, and care of the patient and family at time of death. It concludes with two case examples illustrating the chapter’s content.

Advanced Planning: Evolving Choices and Goals of Care

Health care choices related to wellness are generally viewed as clearcut or easy. We have an infection, we seek treatment, and the problem resolves. Throughout most of the lifespan, medical treatment choices are obvious. As wellness moves along the health care continuum to illness, choices become less clear and consequences of choices have a significantly greater impact.

Many end-of-life illnesses manifest with well-known and well-documented natural courses. Providing the patient and family with information on the natural course of the disease at appropriate intervals is a critical function of health care providers such as nurses. Providing an opening for discussion, such as, “Would you like to talk about the future?” “Do you have any concerns that I can help you address?” or “It seems you are not as active as you were before,” may allow a much-needed discussion of fears and concerns about impending death. Family members may request information that patients do not wish to know at certain points in time. With the patient’s permission, discussions with the family may occur in the patient’s absence. Family members may also need coaching to initiate end-of-life discussions with the patient. End-of-life goal setting is greatly enhanced when the patient is aware of the support of family.

End-of-life care issues should always be discussed with patients and family members. The competent patient is always the acknowledged decision-maker. The involvement of family ensures maximal consensus for patient support as decisions are actually implemented. Decisions for patients who lack decision-making capacity should be made by a consensus approach, using family conference methodology. If documents such as a durable power of attorney for health care or a living will are available, they can be used as a guide for examining wishes that influence decision-making and goal-setting. The decision-maker, usually the person named as health care power of attorney (HCPOA) or the patient’s primary family members, should be clearly identified. This approach may also be used with patients who are able to make their own decisions.

To facilitate decision-making, a family conference involving the decision makers (decisional patient, family members, and the HCPOA), the patient’s physician, nurse, chaplain, and social worker is initiated. A history of how the patient’s health care status evolved from diagnosis to the present is reviewed. The family is presented with the natural course of the disease. Choices on how care may proceed in the future are reviewed. Guidance or support for those choices is provided based on existing data and clinical experience with the particular disease in relation to the current status of the patient. If no consensus for the needed decisions occurs, decision-making is postponed. Third-party support by a trusted individual or consultant may then be enlisted. Personal fundamental values of the patient, family, and physician should be recognized and protected throughout this process.

Decisions by patients and families cross the spectrum of care. They range from continuing treatment for the actual disease, such as undergoing chemotherapy or renal dialysis or utilization of medications, to initiating cardiopulmonary resuscitation (CPR). The health care provider may work with the patient and family, making care decisions for specific treatments and timing treatment discontinuance within a clear and logical framework. A goal-setting discussion may determine a patient’s personal framework for care, such as

- Treatment and enrollment in any clinical studies for which I am eligible
- Treatment as long as statistically there is a greater than 50% chance of response
- Full treatment as long as I am ambulatory and able to come to the clinic or office
- Treatment only of “fixable” conditions such as infections or blood glucose levels
- Treatment only for controlling symptomatic aspects of disease

Once a goal framework has been established with the patient, the appropriateness of interventions such as CPR, renal dialysis, or intravenous antibiotics is clear. For instance, if the patient states a desire for renal dialysis as long as transportation to the clinic is possible without the use of an ambulance, the endpoint of dialysis treatment is quite clear. At this point, the futility of CPR would also be apparent. Allowing a patient to determine when the treatment is a burden that is unjustified by his or her value system, and communicating this determination to family and caregivers, is perhaps the most pivotal point in management of the patient’s care. Table 29–1 suggests a format for an effective and comprehensive family conference.

Changing the Focus of Care as Death Nears

Vital Signs

As nurses, we derive a good deal of security in performing the ritual of measurement of vital signs, one of the hallmarks of
### Table 29-1
Family Conference

| I. Why: | Clarify goals in your own mind. |
| II. Where: | Provide comfort, privacy, circular seating. |
| III. Who: | Include legal decision maker/health care power of attorney; family members; social support; key health care professionals. |
| IV. How: | |
| A. Introduction | |
| 1. Introduce self and others. | |
| 2. Review meeting goals: State meeting goals and specific decisions. | |
| 3. Establish ground rules: Each person will have a chance to ask questions and express views; no interruptions; identify legal decision-maker, and describe importance of supportive decision-making. | |
| B. Review medical status | |
| 1. Review current status, plan, and prognosis. | |
| 2. Ask each family member in turn for any questions about current status, plan, and prognosis. | |
| 3. Defer discussion of decision until the next step. | |
| C. Family discussion with decisional patient | |
| 1. Ask patient, "What decision(s) are you considering?" | |
| 2. Ask each family member, "Do you have questions or concerns about the treatment plan? How can you support the patient?" | |
| D. Family discussion with nondecisional patient | |
| 1. Ask each family member in turn, "What do you believe the patient would choose if he (or she) could speak for himself (or herself)?" | |
| 2. Ask each family member, "What do you think should be done?" | |
| 3. Leave room to let family discuss alone. | |
| 4. If there is consensus, go to V; if no consensus, go to E. | |
| E. When there is no consensus: | |
| 1. Restate goal: “What would the patient say if he or she could speak?” | |
| 2. Use time as ally: Schedule a follow-up conference the next day. | |
| 3. Try further discussion: “What values is your decision based on? How will the decision affect you and other family members?” | |
| 4. Identify legal decision-maker. | |
| 5. Identify resources: minister/priest; other physicians; ethics committee. | |
| V. Wrap-up | |
| 1. Summarize consensus, decisions, and plan. | |
| 2. Caution against unexpected outcomes. | |
| 3. Identify family spokesperson for ongoing communication. | |
| 4. Document in the chart who was present, what decisions were made, follow-up plan. | |
| 5. Approach discontinuation of treatment as an interdisciplinary team, not just as a nursing function. | |
| 6. Continuity: Maintain contact with family and medical team; schedule follow-up meetings as needed. | |
| VI. Family dynamics and decisions | |
| 1. Family structure: Respect the family hierarchy whenever possible. | |
| 2. Established patterns of family interaction will continue. | |
| 3. Unresolved conflicts between family members may be evident. | |
| 4. Past problems with authority figures, doctors, and hospitals affect the process; ask specifically about bad experiences in the past. | |
| 5. Family grieving and decision-making may include | |
| • Denial: False hopes. | |
| • Guilt: Fear of letting go. | |
| • Depression: Passivity and inability to decide; or anger and irritability. | |

*Source: Adapted from Ambuel & Weissman (2001), reference 50. Copyright © 2001, Medical College of Wisconsin, Inc.*
nursing care. When death is approaching, we need to question the rationale for measuring vital signs. Are interventions going to change if it is discovered that the patient has experienced a drop in blood pressure? If the plan of care no longer involves intervening in changes in blood pressure and pulse rate, the measurements should cease. The time spent taking vital signs can then be channeled to assessment of patient comfort and provision of family support. Changes in respiratory rate are visually noted and do not require routine monitoring of rates, unless symptom management issues develop that could be more accurately assessed by measurement of vital signs. The measurement of body temperature using a noninvasive route should continue on a regular basis until death, allowing for the detection and management of fever, a frequent symptom that can cause distress and may require management.

Fever often suggests infection. As death approaches, goal setting should include a discussion of the nontreatment of infection. Indications for treatment of infection are based on the degree of distress and patient discomfort. Pharmacological management of fever should be available with antipyretics, including acetaminophen, and nonsteroidal antiinflammatory drugs for all patients. Ice packs, alcohol baths, and cooling blankets should be used cautiously, because they often cause more distress than the fever itself.

Fever may also suggest dehydration. As with the management of fever, interventions are guided by the degree of distress and patient discomfort. The appropriateness of beginning artificial hydration for the treatment of fever is based on individual patient assessment.

Cardiopulmonary Resuscitation

Patients and family members may need to discuss the issue of the futility of CPR when death is expected from a terminal illness. Developed in the 1960s as a method of restarting the heart in the event of sudden, unexpected clinical death, CPR was originally intended for circumstances in which death was unexpected or accidental. It is not indicated in certain situations, such as cases of terminal irreversible illness where death is not unexpected; resuscitation in these circumstances may represent an active violation of a person’s right to die with dignity.

Over the years, predictors of the success of CPR have become apparent, along with the predictors of the burden of CPR. In general, a poor outcome of CPR is predicted in patients with advanced terminal illnesses, patients with dementia, and patients with poor functional status who depend on others for meeting their basic care needs. Poor outcomes or physical problems resulting from CPR include fractured ribs, punctured lung, brain damage if anoxia has occurred for too long, and permanent unconsciousness or persistent vegetative state. Most importantly, the use of CPR negates the possibility of a peaceful death. This is considered the gravest of poor outcomes.

Artificial Fluids

The issue of artificial hydration is emotional for many patients and families because of the role that giving and consuming fluids plays in our culture. When patients are not able to take fluids, concern surfaces among caregivers. A decision must be reached regarding the appropriate use of fluids within the context of the patient’s framework of goals. Beginning artificial hydration is a relatively easy task, but the decision to stop is generally much more problematic given the emotional implications. Ethical, moral, and most religious viewpoints state that there is no difference between withholding and withdrawing a treatment such as artificial hydration. However, the emotional response attached to withdrawing a treatment adds a world of difference to the decision to suspend. It is therefore much less burdensome to not begin treatment, if this decision is acceptable in light of the specific patient circumstances.

Most patients and families are aware that, without fluids, death will occur quickly. The literature suggests that fluids should not be routinely administered to dying patients, nor automatically withheld from them. Instead, the decision should be based on careful, individual assessment. Zerwekh suggested consideration of the following questions when the choice to initiate or continue hydration is evaluated:

- Is the patient’s well-being enhanced by the overall effect of hydration?
- Which current symptoms are being relieved by artificial hydration?
- Are other end-of-life symptoms being aggravated by the fluids?
- Does hydration improve the patient’s level of consciousness? If so, is this within the patient’s goals and wishes for end-of-life care?
- Does hydration appear to prolong the patient’s survival? If so, is this within the patient’s goals and wishes for end-of-life care?
- What is the effect of the infusion technology on the patient’s well-being, mobility, and ability to interact and be with family?
- What is the burden of the infusion technology on the family in terms of caregiver stress, finance? Is it justified by benefit to the patient?

A study by Fainsinger and Bruera suggested that, although some dying patients may actually benefit from dehydration, others may manifest symptoms such as confusion or opioid toxicity that can be corrected or prevented by parenteral hydration. In any case, the uniqueness of the individual situation, the goals of care, and the comfort of the patient must always be considered when this issue is addressed.

Terminal dehydration refers to the process in which the dying patient’s condition naturally results in a decrease in fluid intake. A gradual withdrawal from activities of daily living may occur as symptoms such as dysphagia, nausea, and fatigue become more obvious. Families commonly ask whether the
patient will be thirsty as fluid intake decreases. In a study at St. Christopher’s Hospice in Sydenham, England, although patients reported thirst, there was no correlation between thirst and hydration, resulting in the assumption that artificial hydration to relieve symptoms may be futile.24 Artificial hydration has the potential to result in fluid accumulation, resulting in distressful symptoms such as edema, ascites, nausea and vomiting, and pulmonary congestion.

Does artificial hydration prolong life? Smith25 cited two studies that reported longer survival times with no artificial hydration. Health care providers need to assist patients and family members to refocus on the natural course of the disease and the notion that the patient’s death will be caused by the disease, not by dehydration, a natural occurrence in advanced illness and dying. Nurses may then assist families in dealing with symptoms caused by dehydration.

Dry mouth, a consistently reported distressing symptom of dehydration, can be relieved with sips of beverages, ice chips, or hard candies.26 Another simple comfort measure for dry mouth is spraying normal saline into the mouth with a spray bottle or atomizer. (Normal saline is made by mixing one teaspoon of table salt in a quart of water.) Meticulous mouth care must be administered to keep the patient’s mouth clean. Family members can be instructed to anticipate this need. The nurse can facilitate this care by ensuring that the necessary provisions are on hand to assist the patient.

**Medications**

Medications unrelated to the terminal diagnosis are generally continued as long as their administration is not burdensome. When swallowing pills becomes too difficult, the medication may be offered in a liquid or other form if available, considering patient and family comfort. Continuing medications, however, may be seen by some patients and families as a way of normalizing daily activities and therefore should be supported. Considerable tact, kindness, and knowledge of the patient and family are needed in assisting them to make decisions about discontinuing medications.

Medications that do not contribute to daily comfort should be evaluated on an individual basis for possible discontinuance. Medications such as antihypertensives, replacement hormones, vitamin supplements, iron preparations, hypoglycemics, long-term antibiotics, antiarrhythmics, laxatives, and diuretics, unless they are essential to patient comfort, can and should be discontinued unless doing so would cause symptoms or discomfort.27 Customarily, the only drugs necessary in the final days of life are analgesics, anticonvulsants, antiemetics, antipyretics, anicholenergic medications, and sedatives.27

**Implantable Cardioverter Defibrillator**

Implantable cardioverter defibrillators (ICDs) are used to prevent cardiac arrest due to ventricular tachycardia or ventricular fibrillation. Patients with ICDs who are dying of another terminal condition may choose to have the defibrillator deactivated, or turned off, so that there will be no interference from the device at the time of death. Patients with ICDs who enter a hospice or palliative care program with diagnoses such as advanced terminal cancer or end-stage renal disease and have decided to stop dialysis are candidates for such consideration.

Patients with ICDs have been instructed to carry a wallet identification card at all times that provides the model and serial number of the implanted device.28 The identification card will also have the name of the physician to contact for assistance. Deactivating the ICD is a simple, noninvasive procedure. Standard practice calls for the patient to sign a consent form. The device is tested after it is turned off to ensure that it is no longer operational, and the test result is placed in the patient record. Patients who are at peace with their impending death find this procedure important to provide assurance that death indeed will be quiet and easy, when it does occur.

**Corticosteroids in Patients with Intracranial Malignancy**

In most cases, the patient with an intracranial malignancy will be receiving a corticosteroid such as dexamethasone to control headaches and seizures caused by intracranial swelling. When the patient is nearing death and is no longer able to swallow, the corticosteroids may be discontinued with minimal or no tapering.29 Discontinuation of the corticosteroid may lead to increased cerebral edema, and, consequently, headache and progressive neurological dysfunction.29 Addition or adjustment of analgesics and anticonvulsant medications may be needed for the patient’s continued comfort.

A patient who is still able to swallow medications may also request that treatment with corticosteroids be stopped because of continued deterioration and poor quality of life. Should this occur, the drug can be tapered, and at the same time an oral anticonvulsant medication can be increased. Careful assessment and control of headache and discomfort should be done twice a day, preferably by the same person. Resumption of the drug at any point is always an option that should be offered to the patient and family if the need becomes apparent.27,29

**Renal Dialysis**

Renal dialysis is a life-sustaining treatment, and as death approaches, it is important to recognize and agree on its limitations. Discontinuation of dialysis should be considered in the following cases26:

- Patients with acute, concurrent illness, who, if they survive, will be burdened with a great deal of disability as defined by the patient and family
- Patients with progressive and untreatable disease or disability
- Patients with dementia or severe neurological deficit

There is general agreement that dialysis should not be used to prolong the dying process.31 The time between discontinuing
dialysis and death varies widely, from a matter of hours or days (for patients with acute illnesses, such as those described earlier) to days, weeks, or even longer if some residual renal function remains.\textsuperscript{30,31} Opening a discussion about the burden of treatment, however, is a delicate task. There may be competing opinions among the patient, family, and even staff about the tolerability or intolerability of continuing treatment. The nurse who sees the patient and family on a regular basis may be the most logical person to recognize the discrete changes in status. Gently validating these observations may open a much-needed discussion regarding the goals of care.

The discussions and decisions surrounding discontinuation or modification of treatment are never easy. Phrases such as, “There is nothing more that can be done” or “We have tried everything” have no place in end-of-life discussions with patients and families. Always reassure the patient and family members—and be prepared to follow through—that you will stand by them and do all you can to provide help and comfort.\textsuperscript{32} This is essential to ensure that palliative care is not interpreted as abandonment.

\section*{Common Signs and Symptoms of Imminent Death and Their Management}

There usually are predictable sets of processes that occur during the final stages of a terminal illness due to gradual hypoxia, respiratory acidosis, metabolic consequences of renal failure, and the signs and symptoms of hypoxic brain function.\textsuperscript{5,33,34} These processes account for the signs and symptoms of imminent death and can assist the nurse in helping the family plan for the actual death.

The following signs and symptoms provide cues that death is only days away:\textsuperscript{5,33,34}:

- Profound weakness (patient is usually bedbound and requires assistance with all or most care)
- Gaunt and pale physical appearance (most common in persons with cancer if corticosteroids have not been used as treatment)
- Drowsiness and/or a reduction in awareness, insight, and perception (often with extended periods of drowsiness, extreme difficulty in concentrating, severely limited attention span, inability to cooperate with caregivers, disorientation to time and place, or semicomatose state)
- Increasing lack of interest in food and fluid with diminished intake (only able to take sips of fluids)
- Increasing difficulty in swallowing oral medications

During the final days, these signs and symptoms become more pronounced, and, as oxygen concentrations drop, new symptoms also appear. Measurement of oxygen concentration in the dying person is not advocated, because it adds discomfort and does not alter the course of care. However, knowledge of the signs and symptoms associated with decreasing oxygen concentrations can assist the nurse in guiding the family as death nears.\textsuperscript{35} As oxygen saturation drops below 80\%, signs and symptoms related to hypoxia appear. As the dying process proceeds, special issues related to normalizing the dying process for the family, symptom control, and patient and family support present themselves. Table 29–2 summarizes the physiological process of dying and suggests interventions for both patients and families.

As the imminently dying person takes in less fluid, thinned fluids, clinically manifested as peripheral edema, acites, or pleural effusions, may be reabsorbed. Breathing may become easier, and there may be less discomfort from tissue distention. Accordingly, as the person experiences dehydration, swelling is often reduced around tumor masses. Patients may experience transient improvements in comfort, including increased mental status and decreased pain. The family needs a careful and compassionate explanation regarding these temporary improvements and encouragement to make the most of this short but potentially meaningful time.

There are multiple patient and family educational tools available to assist families in interpreting the signs and symptoms of approaching death (Figure 29–1). However, as with all aspects of palliative care, consideration of the individual perspective and associated relationships of the patient or family member, the underlying disease course trajectory, anticipated symptoms, and the setting of care is essential for optimal care at all stages of illness, but especially during the final days and hours.

\section*{Care at the Time of Death, Death Rituals, and Facilitating Early Grieving}

At the time of death, the nurse has a unique opportunity to provide information helpful in making decisions about organ and body donation and autopsy. In addition, the nurse can support the family’s choice of death rituals, gently care for the body, assist in funeral planning, and facilitate the early process of grieving.

Family members’ needs around the time of death change, just as the goals of care change. During this important time, plans are reviewed and perhaps refined. Special issues affecting the time of death, such as cultural influences, decisions regarding organ or body donation, and the need for autopsy, are also reviewed.

Under U.S. federal law, if death occurs in a hospital setting, staff must approach the family decision-maker regarding the possibility of organ donation.\textsuperscript{37} Although approaching family at this time may seem onerous, the opportunity to assist another is often comforting. Some hospital-based palliative care programs include information about organ donation in their admission or bereavement information. Readers are urged to review their own organizations’ policies and procedures.
Table 29–2
Symptoms in the Normal Progression of Dying and Suggested Interventions

<table>
<thead>
<tr>
<th>Symptoms Suggested Interventions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Early Stage</strong></td>
</tr>
<tr>
<td><strong>Sensation/Perception</strong></td>
</tr>
<tr>
<td>• Impairment in the ability to grasp ideas and reason; periods of alertness along with periods of disorientation and restlessness are also noted</td>
</tr>
<tr>
<td>• Some loss of visual acuity</td>
</tr>
<tr>
<td>• Increased sensitivity to bright lights while other senses, except hearing, are dulled</td>
</tr>
<tr>
<td><strong>Cardiorespiratory</strong></td>
</tr>
<tr>
<td>• Increased pulse and respiratory rate</td>
</tr>
<tr>
<td>• Agonal respirations or sounds of gasping for air without apparent discomfort</td>
</tr>
<tr>
<td>• Apnea, periodic, or Cheyne-Stokes respirations</td>
</tr>
<tr>
<td>• Inability to cough or clear secretions efficiently, resulting in gurgling or congested breathing (sometimes referred to as the “death rattle”)</td>
</tr>
<tr>
<td>• Interpret the signs and symptoms to the patient (when appropriate) and family as part of the normal dying process; for example, assure them the patient’s “seeing” and even talking to persons who have died is normal and often expected</td>
</tr>
<tr>
<td>• Urge family members to look for metaphors for death in speech and conversation (e.g., talk of a long journey, needing maps or tickets, or in preparing for a trip in other ways) and using these metaphors as a departure point for conversation with the patient</td>
</tr>
<tr>
<td>• Urge family to take advantage of the patient’s periods of lucidity to talk with patient and ensure nothing is left unsaid</td>
</tr>
<tr>
<td>• Encourage family members to touch and speak slowly and gently to the patient without being patronizing</td>
</tr>
<tr>
<td>• Maximize safety; for example, use bedrails and schedule people to sit with the patient</td>
</tr>
<tr>
<td>• Keep sensory stimulation to a minimum, including light, sounds, and visual stimulation; reading to a patient who has enjoyed reading in the past may provide comfort</td>
</tr>
<tr>
<td>• Urge the family to be mindful of what they say “over” the patient, because hearing remains present; also continue to urge family to say what they wish not to be left unsaid</td>
</tr>
<tr>
<td><strong>Renal/Urinary</strong></td>
</tr>
<tr>
<td>• Decreasing urinary output, sometimes urinary incontinence or retention</td>
</tr>
<tr>
<td>• Insert catheter and/or use absorbent padding</td>
</tr>
<tr>
<td>• Carefully assess for urinary retention, because restlessness can be a related symptom</td>
</tr>
<tr>
<td>• Reposition every few hours as appropriate</td>
</tr>
<tr>
<td>• Anticipate needs such as sips of fluids, oral care, changing of bed pads and linens, and so on</td>
</tr>
<tr>
<td>• Normalize the observed changes by interpreting the signs and symptoms as part of the normal dying process and ensuring the patient’s comfort</td>
</tr>
<tr>
<td>• Assess and treat respiratory distress as appropriate</td>
</tr>
<tr>
<td>• Assess use and need for parenteral fluids, tube feedings, or hydration. (It is generally appropriate to either discontinue or greatly decrease these at this point in time.)</td>
</tr>
<tr>
<td>• Reposition the patient in a side-lying position with the head of the bed elevated</td>
</tr>
<tr>
<td>• Suctioning is rarely needed, but when appropriate, suction should be gentle and only at the level of the mouth, throat, and nasal pharynx</td>
</tr>
<tr>
<td>• Administer anticholinergic drugs (transdermal scopolamine, hyoscyamine) as appropriate, recognizing and discussing with the family that they will not decrease already existing secretions.</td>
</tr>
<tr>
<td><strong>Musculoskeletal</strong></td>
</tr>
<tr>
<td>• Gradual loss of the ability to move, beginning with the legs, then progressing</td>
</tr>
<tr>
<td>• Reposition every few hours as appropriate</td>
</tr>
<tr>
<td>• Anticipate needs such as sips of fluids, oral care, changing of bed pads and linens, and so on</td>
</tr>

</table>

In any case, it is important to clarify specifically with family members what their desires and needs are at the time of death. Do they wish to be present? Do they know of others who wish to now say a final goodbye? Have they said everything they wish to say to the person who is dying? Do they have any regrets? Are they concerned about anything? Do they wish something could be different? Every person in a family has different and unique needs that, unless explored, can go unmet. Family members recall the time before the death and immediately afterward with great acuity and detail. As mentioned earlier, there is no chance for a dress rehearsal—we only have the one chance to “get it right” and make the experience an individual and memorable one.

Although an expected death can be anticipated with some degree of certainty, the exact time of death is often not predictable. Death often occurs when no health care professionals are present. Frequently, dying people seem to determine the time of their own death—for example, waiting for someone to arrive, for a date or event to pass, or even for family members to leave—even if the leave-taking is brief. For this reason, it is crucial to ask family members who wish to be present at the time of death whether they have thought about the possibility they will not be there. This opens an essential discussion regarding the time of death and its unpredictability. Gently reminding family members of that possibility can assist them in preparing for any eventuality.

**Determining That Death Has Occurred**

Death often occurs when health professionals are not present at the bedside or in the home. Regardless of the site of death, a plan must be in place for who will be contacted, how the death pronouncement will be handled, and how the body will be removed. This is especially crucial for deaths that occur outside a health care institution.

Death pronouncement procedures vary from state to state, and sometimes from county to county within a state. In some states, nurses can pronounce death; in others, they cannot. In inpatient settings, the organization’s policy and procedures are followed. In hospice home care, generally the nurse makes a home visit, assesses the lack of vital signs, contacts the physician who verbally agrees to sign the death certificate, and then contacts the funeral home or mortuary. Local customs, the ability of a health care agency to ensure the safety of a nurse during the home visit, and provision for “do-not-resuscitate” orders outside a hospital setting, among other factors, account for wide variability in the practices and procedures surrounding pronouncement of death in the home. Although practices vary widely, the police or coroner may need to be called if the circumstances of the death were unusual, were associated with trauma (regardless of the cause of the death), or occurred within 24 hours of a hospital admission.38
SIGNS AND SYMPTOMS OF APPROACHING DEATH

This list of symptoms and what to do about them may appear frightening, but
knowing what to expect may reduce some of your anxiety about the approaching death.

Each person approaches death in their own way, bringing to this last experience
their own uniqueness. Our list of "Symptoms and What To Do" is a map to the goal of a
peaceful death. Like all maps, there are many different routes to the same destination.

You may see all of these symptoms or none. Death will come in its own time, and its
own way to each of us. It is important to remember that dying is a natural process.

1. Withdrawal - Physical and emotional, and increased sleep.
   Natural process of withdrawing from everything outside of one's self, looking
   inward, reviewing one's self and one's life. Your loved one may turn inward, withdraw
   physically and emotionally. This occurs in an attempt to cope with the many changes
   that are occurring.

2. Reduced food and fluid intake.
   Decreased need because body will naturally begin to conserve energy.
   Dehydration is a natural comfort measure, since the body systems can't
   process fluids effectively. At no time should food/fluids be forced.

3. Confusion/Agitation can vary from mild to end stage agitation which
   may include trying to get out of bed, picking at covers, seeing
   things that are not apparent to us.
   Talk calmly and assuredly. Keep lights on, use times when patient is alert for
   meaningful conversation. Music can be very calming. Medication often used to
   control this symptom.

<th></th>
<th>Description</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Change in breathing patterns.</td>
<td>This is common. You may see irregular breathing: very rapid, very slow, and/or 10 to 30 seconds of no breathing at all (called apnea). These symptoms are very common and indicative of a decrease in circulation. It does not mean that your loved one is uncomfortable or struggling.</td>
</tr>
</tbody>
</table>
| 5 | Oral secretions collect in back of throat causing noisy respiration.         | Swallowing reflex may be absent. Patient may be breathing through the secretions.  
  • This may be more uncomfortable for us as observers than patient experiencing it.  
  • Elevate head of bed or turn patient on side. |
| 6 | Incontinence of urine and stool.                                             | Reduced intake results in reduced output with darker color. Bedpads and diapers can be used to protect bed linens. Cleanse patient and change linens frequently to maintain comfort and protect skin. |
| 7 | Changes in skin temperature and color.                                      | Decreased circulation can cause coolness and discoloration of skin. Use light covers, turn side to side frequently to maintain comfort and prevent skin breakdown (bedsores). Heating pads and electric blankets NOT recommended. |

Hearing is the last sense to be lost, so the patient can hear all that is being said. This is a good time to say good-by, reassure them that you will be all right even though you will miss them greatly. (You may tell them it’s OK to “let go”.) This permission is often helpful for a peaceful death.

How would you know death has occurred?
1. No breathing
2. No heartbeat or pulse

If you believe that death has occurred, call Hospice at 449-7740. Do not call 911 or the physician. We will come to your home to help you. (You may want to use the time until we arrive to say your last good-bye.)

signs & symptoms death: 7/04
The practice of actual death pronouncement varies widely and is not often taught in medical school or residencies.\(^{38}\) The customary procedure is to, first, identify the patient, then note the following:\(^{39}\):

- General appearance of the body
- Lack of reaction to verbal or tactile stimuli
- Lack of pupillary light reflex (pupils will be fixed and dilated)
- Absent breathing and lung sounds
- Absent carotid and apical pulses (in some situations, listening for an apical pulse for a full minute is advisable)

Documentation of the death is equally important and should be thorough and clear. The following guidelines are suggested:\(^{38,39}\):

- Patient’s name and time of call
- Who was present at the time of death and at the time of the pronouncement
- Detailed findings of the physical examination
- Date and time of death pronouncement (either pronouncement by the nurse or the time at which the physician either assessed the patient or was notified)
- Who else was notified and when—for example, additional family members, attending physician, or other staff members
- Whether the coroner was notified, rationale, and outcome, if known
- Special plans for disposition and outcome (e.g., organ or body donation, autopsy, special care related to cultural or religious traditions)

**Care of the Body After Death**

Regardless of the site of death, care of the body is an important nursing function. In gently caring for the body, the nurse can continue to communicate care and concern for the patient and family members and model behaviors that may be helpful as the family members continue their important grief work. Caring for the body after death also calls for an understanding of the physiological changes that occur. By understanding these changes, the nurse can interpret and dispel any myths and explain these changes to the family members, thereby assisting the family in making their own personal decisions about the time immediately following death and funeral plans.

A time-honored and classic article regarding postmortem care, emphasized that, although postmortem care may be a ritualized nursing procedure, the scientific rationale for the procedure rests on the basics of the physiological changes that occur after death.\(^{40}\) These changes occur at a regular rate depending on the temperature of the body at the time of death, the size of the body, the extent of infection (if any), and the temperature of the air. The three important physiological changes—rigor mortis, algor mortis, and postmortem decomposition—are discussed along with the relevant nursing implications in Table 29–3.

Care of and respect for the body after death by nursing staff should clearly communicate to the family that the person who died was indeed important and valued. Often, caring for the body after death provides the needed link between family members and the reality of the death, recognizing that everyone present at the time of death and soon after will have a different experience and a different sense of loss. Many institutions no longer require nursing staff to care for patients after death or perform postmortem care.\(^{41}\) Further, the only published resources related to postmortem care are a series of three articles describing the procedure of "last offices" published in a British journal in 1998.\(^{33–35}\) In a 1999 review of nursing textbooks, only 26% covered this important aspect of nursing care.\(^{36}\) Family members will long remember the actions of the nurse after the death. A kind, gentle approach and meticulous attention to detail are imperative.

Rituals that family members and others present find comforting should be encouraged. Rituals are practices within a social context that facilitate and provide ways to understand and cope with the contradictory and complex nature of human existence. They provide a means to express and contain strong emotions, ease feelings of anxiety and impotence, and provide structure in times of chaos and disorder.\(^{42}\) Rituals can take many forms—a brief service at the time of death, a special preparation of the body as in the Orthodox Jewish tradition, or an Irish wake, where, after paying respect to the person who has died, family and friends gather to share stories, food, and drink. Of utmost importance, however, is to ensure that family members see the ritual as comforting and meaningful. It is the family’s needs and desires that direct this activity—not the nurse’s. There are, again, no rules that govern the appropriateness of rituals; rituals are comforting and serve to begin the process of healing and acceptance.

To facilitate the grieving process, it is often helpful to create a pleasant, peaceful, and comfortable environment for family members who wish to spend time with the body, according to their desires and cultural or religious traditions. The nurse should consider engaging family members in after-death care and ritual by inviting them to either comb the hair or wash the person's hands and face, or more, if they are comfortable. Parents can be encouraged to hold and cuddle their baby or child. Including siblings or other involved children in rituals, traditions, and other end-of-life care activities according to their developmental level is also essential. During this time, family members should be invited to talk about their loved one and encouraged to reminisce—valuable rituals that can help them begin to work through their grief.\(^{43}\)

The family should be encouraged to touch, hold, and kiss the person's body, as they feel comfortable. Parents may wish to clip and save a lock of hair as a keepsake. The nurse may offer to dress the person's body in something other than a hospital gown or other nightclothes. Babies may be wrapped snugly in a blanket. Many families choose to dress the body in
a favorite article of clothing before removal by the funeral home. It should be noted that, at times, when a body is being turned, air escapes from the lungs, producing a "sighing" sound. Informing family members of this possibility is wise. Again, modeling gentle and careful handling of the body can communicate care and concern on the part of the nurse and facilitate grieving and the creation of positive and long-lasting memories.

Postmortem care also includes, unless an autopsy or the coroner is involved, removal of any tubes, drains, and other devices. In home care settings, these can be placed in a plastic bag and given to the funeral home for disposal as medical waste or simply double-bagged and placed in the family's regular trash. Placing a waterproof pad, diaper, or adult incontinence brief on the patient often prevents soiling and odor as the patient's body is moved and the rectal and urinary bladder sphincters relax. Packing of the rectum and vagina is considered unnecessary, because not allowing these areas to drain increases the rate of bacterial proliferation that naturally occurs.41

<table>
<thead>
<tr>
<th>Change</th>
<th>Underlying Mechanisms</th>
<th>Nursing Implications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rigor mortis</td>
<td>Approximately 2 to 4 hours after death, adenosine phosphate (ATP) ceases to be synthesized due to the depletion of glycogen stores. ATP is necessary for muscle fiber relaxation, so the lack of ATP results in an exaggerated contraction of the muscle fibers that eventually immobilizes the joints. Rigor begins in the involuntary muscles (heart, gastrointestinal tract, bladder, arteries) and progresses to the muscles of the head and neck, trunk and lower limbs. After approximately 96 hours, however, muscle chemical activity totally ceases, and rigor passes. Persons with large muscle mass (e.g., body builders) are prone to more pronounced rigor mortis. Conversely, frail elderly persons and persons who have been bed bound for long periods are less subject to rigor mortis.41</td>
<td>In many cultures, the body is viewed within 24–48 hours after death. Therefore, post-death positioning becomes of utmost importance. In many cases, it is important to be sure the eyelids and jaw are closed and dentures are in place in the mouth. (Rolling a towel and placing it under the jaw often helps to keep it closed.) The position of the hands is also important. Position all limbs in proper body alignment. If rigor mortis does occur, it can often be &quot;massaged out&quot; by the funeral director.41 Finally, by understanding this physiology, the nurse can also reassure the family about the myth that due to rigor mortis, muscles can suddenly contract and the body can appear to move.</td>
</tr>
<tr>
<td>Algor mortis</td>
<td>After the circulation ceases and the hypothalamus stops functioning, internal body temperature drops by approximately 1° C or 1.8° F per hour until it reaches room temperature. As the body cools, skin loses its natural elasticity. If a high fever was present at death, the changes in body temperature are more pronounced and the person may appear to &quot;sweat&quot; after death. Body cooling may also take several more hours.41</td>
<td>The nurse can prepare family members for the coolness of the skin to touch or the increased moisture by explaining the changes that happen after death. The nurse may also suggest kissing the person on their hair instead of their skin. The skin, due to loss of elasticity, becomes fragile and easily torn. If dressings are to be applied, it is best to apply them with either a circular bandage or paper tape. Handle the body gently as well, being sure to not place traction on the skin.</td>
</tr>
<tr>
<td>Postmortem decomposition or &quot;liver mortis&quot;</td>
<td>Discoloration and softening of the body are caused largely by the breakdown of red blood cells and the resultant release of hemoglobin that stains the vessel walls and surrounding tissue. This staining appears as a mottling, bruising, or both in the dependent parts of the body as well as parts of the body where the skin has been punctured (e.g., intravenous or chest tube sites).41 Often this discoloration becomes extensive in a very short time. The remainder of the body has a gray hue. In cardiac-related deaths, the face often appears purple in color regardless of the positioning at or after death.41</td>
<td>As the body is handled (e.g., while bathing and dressing), the nurse informs the family member about this normal change that occurs after death.</td>
</tr>
</tbody>
</table>
Occasionally families, especially in the home care setting, wish to keep the person’s body at home, perhaps to wait for another family member to come from a distance and to ensure that everyone has adequate time with the deceased. If the family wishes the body to be embalmed, this is best done within 12 hours. If embalming is not desired, the body can remain in the home for approximately 24 hours before further decomposition and odor production occur. The nurse should suggest to the family that they make the immediate area cooler to slow down natural decomposition, either by turning down the furnace or by turning up the air conditioning. Be sure, however, to inform the funeral director that the family has chosen to keep the body at home a little longer. Finally, funeral directors are a reliable source of information regarding postdeath changes, local customs, and cultural issues.

The care of patients and families near the time of death and afterward is an important nursing function—arguably one of the most important. As the following case studies are reviewed, consider how the nurse interceded in a positive manner, mindful of the changing tempo of care and the changing patient and family needs, desires, and perspectives.

CASE STUDY
James, a 45-Year-Old Man with Amyotrophic Lateral Sclerosis

James was a 45-year-old, self-employed investment banker with a 2-year history of rapidly progressive amyotrophic lateral sclerosis (ALS). After unsuccessful treatment, including participation in clinical trials, James, with the blessing of his wife, Ruth, and their adult children, decided to focus on symptom management and ensuring the quality of his remaining life. However, when his physician suggested hospice, he resisted, claiming that “hospice” was synonymous with death, and, although he knew he was dying, he did not feel the need to talk about it outside of his immediate family. He also stated that he wanted time to sell his business and ensure that his long-time clients had continuity. His physician consulted the palliative care team at the hospital where James had received care, and James and Ruth agreed to meet with the palliative care clinical nurse specialist that day.

Goals and framework of care: Gentle and respectful explanation of the available options and their meaning for care, first understanding and then incorporating James’ and his family’s goals and needs.

After meeting with the clinical nurse specialist, James and Ruth agreed they would think about a referral to the local hospice program. The following week, they enrolled and became acquainted with the hospice staff members who would be overseeing their care. James also decided to update his durable power of attorney for health care and to formalize his wish to not be resuscitated by wearing a bracelet communicating his wishes to the area emergency medical services. James’s symptoms were well controlled and he was able to get out of the house with his wheelchair. Sometimes, a hospice volunteer would come and take him out to his favorite park. Although rapidly losing strength, he expressed a wish to go on a cruise with Ruth and his children.

Goals and framework of care: Although they believed it to be inadvisable, the hospice staff chose to facilitate and honor James’s wish despite his progressive illness. They advocated for him and his family with the cruise line and remained in communication with the physician and nurse on the cruise ship.

James and his family had an incredible “trip of a lifetime,” according to James, but soon after their return he became increasingly weak, unable to swallow, and unable to breathe without continuous positive airway pressure (CPAP).

Goals and framework of care: The hospice staff revisited James’ goals in the context of his declining strength, understanding that there might indeed be things James wanted to accomplish before he died. They held a family meeting with James, Ruth, and the children to answer questions and discuss how his illness might progress. James made the decision to not use the CPAP any longer, and the hospice staff assured him that his symptoms would be well controlled.

The hospice provided volunteers who assisted James in transitioning his clients to the new owner of his business. As his illness worsened, his parents and siblings took turns coming and staying with James and Ruth. This gave Ruth needed respite from caregiving and James time alone with his parents—which had rarely happened in the past—as well as time alone with each of his siblings. The nurse was able to inform the family when his death neared, so all of the family members were present, as James had wished, when he died. During the visit at the time of James’ death, Ruth helped the nurse prepare James’ body for transportation to the mortuary, even choosing to dress James in his favorite flannel shirt. The nurse and James’ wife, children, parents, and siblings reflected on how they had worked together and had empowered each other so that they could make this difficult experience James’ very own.

Goals and framework of care: The goals of care changed again to assisting James with accomplishing his final wishes and ensuring that his continued care needs were addressed. At the same time, James family began to prepare for his death by participating in early grief work.

Critical Points
• Coming to grips with death is a process and cannot be rushed. It is different for everyone.
• The needs of James and his family were listened to, honored, and not questioned or challenged.
He and his family remained in charge and in control.

- Time-of-death rituals—i.e., bathing and dressing the body—can often be comforting and memorable for family members.
- The care of a patient and family at end of life includes all family members, not just the immediate family. By supporting James’ entire family, comforting memories were ensured.

CASE STUDY
Mrs. H, a 40-Year-Old Woman with Cancer of Unknown Origin

Mrs. H first presented to her primary care physician after noticing a new mass under her arm. The mass was biopsied and was determined to be an adenocarcinoma of unknown origin. Subsequent workup showed no evidence of disease elsewhere. Mammography, computed tomography, magnetic resonance imaging (MRI), chest radiography, and colonoscopy were negative. The biopsy slides were sent to another institution for review. After extensive review, it was determined that her cancer most closely mimicked the breast in origin, and treatment was begun based on that knowledge. The workup took approximately 3 weeks, a time of great anxiety for the patient and her family.

Mrs. H settled into chemotherapy on a weekly basis; her husband and sister accompanied her to her treatment sessions. She was employed by a local company who had pledged their full support to her in terms of job security and support by their staff for any needs. She was the mother of two children in college. Mrs. H reported that “life was full and good!”

Mrs. H asked for information on support programs. It was difficult for her to find appropriate group support, so she opted for individual counseling. She shared that she did not believe the situation was going to have a positive outcome. She desperately wanted to have a “kitchen table” conversation with her family but never felt successful in doing so. With the support of the nursing staff and social services staff, she set-
tled for completing her advanced directive and putting her wishes in writing.

Goals and framework of care: “Treat and See”

Treatment continued for 6 months. No evidence of disease was noted after 4 months. It was determined that after 1 more month, treatments would be stopped and surveillance would begin. A feeling of relief and joy surrounded Mrs. H during her clinic visits. During her last month of treatment, antiemetic treatment was noted to be more difficult, and dexamethasone was added to the treatment regimen.

A month after her last treatment, Mrs. H presented to clinic with a severe headache. An immediate MRI was ordered. Before it could be completed, Mrs. H became unconscious and was admitted to the intensive care unit (ICU). The results showed a brain mass compounded by a massive intracranial bleed.

Goals and framework of care: “Understanding the New Findings”

Comprehending the dramatic shift in the patient’s condition, the extent of the disease, and the implications of the new findings was overwhelming to the family. Treating staff also struggled with the new findings. Time was needed. How much, though? How quickly could the family be moved to decision-making concerning life support for Mrs. H?

Clearly, a good deal of support would be needed for the family and staff. The family was asked to gather and to bring other supportive individuals who could assist them. Thirty-six hours after the MRI was done, the family gathered to hear the status of Mrs. H’s condition and her prognosis. They were asked to consider what her wishes would be under the circumstances. Mrs. H’s advance directive was reviewed; it clearly stated that she wished no advanced life support if meaningful recovery was not believed possible. The family was immobilized by the situation. They were asked to appoint a family spokesperson who could meet the next morning with the attending physician.

Goals and framework of care: “Continuing the Dialogue—Allowing for Time”

The next morning, the family spokesperson did not arrive to meet with the attending physician as planned. There were no phone calls from the family, and no communication from them for 24 hours. At this point, the family spokesperson was contacted by Mrs. H’s nurse simply for the purpose of providing an update on Mrs. H’s condition and asking if there were further questions. The reply was simply, “Thank you, no.” The spokesperson shared with the nurse that the family simply did not know what to do and were not ready to come back to the hospital. They asked for more time. The ICU team agreed that, if there was no contact from the family by noon of the next day, Mrs. H’s oncologist, who had been present at the family meeting, would make the next contact.

The next morning, the entire family arrived at the hospital and asked to plan with the team the most dignified way to remove Mrs. H from life support. They brought personal items, pictures of the family, their minister, and a special prayer to be read. The staff employed aggressive dyspnea management for Mrs. H and removed her from life support in the presence of her family. She died peacefully within 30 minutes after removal from the ventilator. Surrounded by the love of her family, who gave each other the support, Mrs. H died, much in the way the nursing staff in the oncology unit had heard her describe.
Assisting and walking alongside dying patients and their families, especially near and after death, is an honor and privilege. Nowhere else in the practice of nursing are we invited to be companions on such a remarkable journey as that of a dying patient and family. Likewise, nowhere else in the practice of nursing are our words, actions, and guidance more remembered and cherished. Caring for dying patients and families is indeed the essence of nursing. Take this responsibility seriously, understanding that, although it may be stressful and difficult at times, it comes with personal and professional satisfaction beyond measure. Listen to your patients and their families. They are the guides to this remarkable and momentous journey. Listen to them with a positive regard, empathy, and genuineness, and approach their care with an acute attention to every detail. They—in fact, all of us—are counting on you.

Critical Points

- Sudden changes in trajectories of care require time for the family to adjust, particularly if the patient is no longer able to speak or make decisions. Allowing realistic time frames for this process is critical.
- Frameworks of care must be clear to the patient, family, and all staff members involved in the patient’s care throughout the process of treatment.

Spiritual Care
This page intentionally left blank
Spiritual Assessment

I agree that spiritual support is very important during a serious illness, but I also believe that it is a choice for the patients to make for themselves whether it be interactive with a professional caregiver. Some people prefer an intimate, personal relationship with God and may not feel comfortable revealing themselves. Others may welcome the genuine love and concern of others. It would have to be approached with utmost sensitivity and knowledge of people and their relationship with God.
—Spouse responding to a written survey

To solve any problem, one must first assess what the problem is. Consequently, the nursing process dictates that the nurse begin care with an assessment of the patient’s health needs. Although palliative nurses are accustomed to assessing patients’ pain experiences, hydration status, and so forth, they less frequently participate in assessing patients’ and family members’ spirituality.

Because spirituality is an inherent and integrating, and often extremely valued, dimension for those who receive palliative nursing care, it is essential that palliative care nurses know to some degree how to conduct a spiritual assessment. This chapter reviews models for spiritual assessment, presents general guidelines on how to conduct a spiritual assessment, and discusses what the nurse ought to do with data from a spiritual assessment. These topics are prefaced by arguments supporting the need for spiritual assessments, descriptions of what spirituality “looks like” among the terminally ill, and risk factors for those who are likely to experience spiritual distress. But first, a description of spirituality is in order.

What Is Spirituality?

A number of recent analyses of the concept of spirituality have identified key aspects of this ethereal and intangible phenomenon. Conceptualizations of spirituality often include the following as aspects of spirituality: the need for purpose and meaning, forgiveness, love and relatedness, hope, creativity, and religious faith and its expression. A well-accepted definition for spirituality authored by Reed proposed that spirituality involves meaning-making through intrapersonal, interpersonal, and transpersonal connection. A more recent definition that incorporates themes found in nursing literature is Dossey and Guzzetta’s description of “a unifying force of a person; the essence of being that permeates all of life and is manifested
in one’s being, knowing, and doing; the interconnectedness with self, others, nature, and God/Life Force/Absolute/Transcendent” (p. 7).

Usually, spirituality is differentiated from religion—the organized, codified, and often institutionalized beliefs and practices that express one’s spirituality. As Dossey and Guzzetta’s definition illustrates, care is often taken to allow for an open interpretation of what a person considers to be divine, or a transcendent Other. Although health care literature frequently uses phrases such as “higher power” in addition to “God,” demographers of religion find that more than 90% of Americans believe in God.

The spiritual assessment methods introduced in this chapter are all influenced inherently by some conceptualization of spirituality. Some, however, have questioned whether spiritual assessment is possible, given the broad, encompassing definition typically espoused by nurses. Bash contended that spirituality is an “elastic” term that cannot be universally defined. Because a patient’s definition of spirituality may differ from the nurse’s assumptions about it, Bash argued that widely applicable tools for spiritual assessment are impossible to design. It is important to note, therefore, that the literature and methods for spiritual assessment presented in this chapter are primarily from the United States and United Kingdom, influenced most by Western Judeo-Christian traditions and peoples. Hence, they are most applicable to these peoples.

Why Is It Important for a Palliative Care Nurse to Conduct a Spiritual Assessment?

Spiritual awareness increases as one faces an imminent death. While some may experience spiritual distress or “soul pain,” others may have a spiritual transformation or experience spiritual growth and health. There is mounting empirical evidence to suggest that persons with terminal illnesses consider spirituality to be one of the most important contributors to quality of life. For example, two studies measuring various domains of quality of life found spiritual well-being to rank highest in samples of hospice patients. McClain and colleagues observed that spiritual well-being functioned to protect terminal cancer patients against end-of-life despair. They found spiritual well-being to have moderately strong inverse relationships with the desire for a hastened death, hopelessness, and suicidal ideations. Religious beliefs and practices (e.g., prayer, beliefs that explain suffering or death) are also known to be valued and frequently used as helpful coping strategies among those who suffer and die from physical illness. Family caregivers of seriously ill patients also find comfort and strength from their spirituality that assists them to cope. A national telephone survey of 1200 adults also confirmed that Americans project that their spiritual beliefs (e.g., beliefs in an afterlife, beliefs about life belonging to God, and being “born again”) will be important sources of comfort when they are dying.

The above themes from research imply that attention to the spirituality of terminally ill patients and their caregivers is of utmost importance. That is, if patients’ spiritual resources assist them to cope, and if imminent death precipitates heightened spiritual awareness and concerns, and if patients view their spiritual health as most important to their quality of life, then spiritual assessment that initiates a process promoting spiritual health is vital to effective palliative care.

Underscoring these theoretical reasons for spiritual assessment is a very pragmatic one: the mandate of the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) to conduct a spiritual assessment for clients entering an approved facility. The Joint Commission states that a spiritual assessment, at least, should “determine the patients denomination, beliefs, and what spiritual practices are important.” They do not stipulate how this assessment should be conducted, allowing the institution to develop its own process.

But why should palliative care nurses be conducting spiritual assessments? Hunt and colleagues recognized that although chaplains are the spiritual care experts, all members of a hospice team participate in spiritual caregiving. In surveying hospice team members, Millison and Dudley found nurses are often the ones responsible for completing spiritual assessments. Other nurse authors imply that nurses are pivotal in the process of spiritual assessment. Considering nurses’ frontline position, coordination role, and intimacy with the concerns of patients, the holistic perspective on care, and even their lack of religious cloaking, nurses are ideal professionals for completing a spiritual assessment.

However, nurses must recognize that they are not specialists in spiritual assessment and caregiving; they are generalists. Most oncology and hospice nurses perceive that they do not receive adequate training in spiritual assessment and care. In fact, it is this lack of training, accompanied by role confusion, lack of time, and other factors that nurses often cite as barriers to completing spiritual assessments. When a nurse’s assessment indicates need for further sensitive assessment and specialized care, a referral to a specialist (e.g., chaplain, clergy, patient’s spiritual director) is in order.

How Does Spirituality Manifest Itself?

To understand how to assess spirituality, the palliative care nurse must know what to look for. What subjective and objective observations would indicate spiritual disease or health? To approach an answer, it is helpful to consider two research studies exploring qualitatively what are clients’ perceptions of spiritual need. Hermann interviewed 19 hospice patients to determine what specifically their spiritual needs were. The 29 resulting spiritual needs were categorized under the following...
themes: need for involvement and control, need for companionship, need to finish business, need to experience nature, need for a positive outlook, as well as need for religion. Taylor interviewed 28 cancer patients and family caregivers, some for whom death was imminent, and identified eight categories of spiritual need. These spiritual needs included the need to:

- Relate to God or an Ultimate Other (e.g., the need to believe God will or has healed, the need to remember God’s providence, the need to remember that “there is Someone out there looking out for me”)
- Have gratitude and optimism (e.g., the need to keep a positive outlook, to count one’s blessings, or just enjoy life)
- Love others (e.g., to forgive or “get right” with others, to return others’ kindnesses, to make the world a better place, to protect family members from witnessing the suffering from cancer)
- Receive love from others (e.g., the need to feel valued and appreciated by family, to know others are praying for you, or just being with others considered to be family)
- Review spiritual beliefs (e.g., wondering if religious beliefs are correct, thinking about the unfairness of personal circumstances, or asking “why?” questions)
- Create meaning, find purpose for cancer and for life (e.g., the need to “get past” asking “why me?” and becoming aware of positive outcomes from illness, lessening the frustration of not being able to do meaningful work, or sensing that there is a reason for being alive)
- Sustain religious experience (e.g., reading spiritual nurturing material, having quiet time to reflect, or receiving a sacrament from a religious leader)
- Prepare for death (e.g., balancing thoughts about dying with hoping for health, cognitively creating a purpose for death, or making sure personal business is in order).

Dudley and colleagues found hospice spiritual assessment forms often include more specific spiritual problems, such as fear of death or abandonment, spiritual emptiness, unresolved grief, unresolved past experiences, confusion or doubts about beliefs, and the need for reconciliation, comfort, or peace.

Although the terminology “spiritual need” may suggest a problem, spiritual needs can also be of a positive nature. For example, patients can have a need to express their joy about sensing closeness to others, or have a need to pursue activities that allow expression of creative impulses (e.g., artwork, music making, writing). Although the following models for conducting a spiritual assessment will provide more understanding of how spirituality manifests, the reader is referred to Taylor or Carpenito, or Highfield and Cason’s seminal article for further concrete indicators of spiritual need.

Spiritual Assessment Models

Health care professionals from multiple disciplines offer models for spiritual assessment. Selected models from chaplaincy and pastoral counseling, medicine (including psychiatry), and nursing will be presented here. Although some assessment models have been published during the past few years, most were developed in the 1990s, when the research about spiritual care began to proliferate.

Chaplaincy/Pastoral Counseling

During the past several decades, as the field of chaplaincy and pastoral counseling has advanced, there have been several models for spiritual assessment published. However, most discussions of spiritual assessment in this field reflect the ideas of the Christian psychologist Pruyser.

Pruyser proposed seven dimensions or traits to spirituality. Each dimension can be considered a continuum, with negative and unhealthy versus positive and healthy ends. These dimensions are presented in Table 30–1 with statements that terminally ill patients or their loved ones might make to illustrate each end of the continuum. Where a patient is on these continuums can change over time. Malony asserted that one more dimension needs to be added to Pruyser’s seven, a trait Malony labels “openness in faith.” That is, a positive, healthy sense of openness in faith allows an individual to not be rigid or resistant to new ideas in his or her spiritual beliefs. Although Pruyser and Malony acknowledge this model as being molded by Christian perspectives, much of the model still offers non-Christians insight into what spiritual dimensions can encompass.

Fitchett developed the “7 by 7” model for spiritual assessment. In addition to reviewing seven dimensions of a person (medical, psychological, psychosocial, family system, ethnic and cultural, societal issues, and spiritual dimensions), Fitchett advances seven spiritual dimensions to include in an assessment: beliefs and meaning (i.e., mission, purpose, religious and nonreligious meaning in life), vocation and consequences (what persons believe they should do, what their calling is), experience (of the divine or demonic) and emotion (the tone emerging from one’s spiritual experience), courage and growth (the ability to encounter doubt and inner change), ritual and practice (activities that make life meaningful), community (involvement in any formal or informal community that shares spiritual beliefs and practices), and authority and guidance (exploring where or with whom one places trusts, seeks guidance).

Using an approach less complex than Fitchett’s, van der Poel offers five general questions for organizing the assessment of an incurably ill patient: What is the place of God in the patient’s life? What is the patient’s attitude toward self? How is the patient’s relationship with family and friends? What is the patient’s understanding of and interest in prayer? What is the patient’s attitude toward his or her religion? Van
der Poel does specify substatements for each of these questions, but offers them in a tool that quantifies (using five-point response options) patient responses.

Hospice chaplain Muncy assesses three dimensions of patients’ spirituality. First, patient’s self-understanding and attitudes about others are explored, since, in Muncy’s view, how patients view self and others frequently portrays their view of God. Second, religious and spiritual history, including sense of purpose, are assessed. Last, patients are asked about their spiritual goals; this allows the clinician to discuss with the patient a plan for spiritual care.

Medicine

A number of physicians have offered approaches to spiritual assessment.42–43 Most of these approaches befit the work of a physician or other health care professional who is needing to screen for spiritual need in an efficient way. These approaches generally involve asking about specified aspects of spirituality during a history taking. To remember these aspects of spirituality, many are organized to reflect a mnemonic. Several of these are summarized and illustrated in Table 30–2.

The Royal Free Interview Schedule developed in the United Kingdom by King, Speck, and Thomas is a 2½-page self-report questionnaire. The tool showed acceptable reliability and various forms of validity when it was tested among 297 persons, who were primarily hospital employees and church members. Questionnaire items assess both spiritual and religious “understanding in life” (1 item), religious/spiritual beliefs (8 items), religious/spiritual practices (3 items), and “intense” spiritual or “near death” experiences (6 items). Response options for items include Likert scales, categorical options, and space for answering open-ended questions.

Family physician T.A. Maugens offers the mnemonic SPIRIT for remembering six components to cover during a spiritual assessment, or “history” (to use Maugens’s physician terminology). “Spiritual belief system” refers to religious affiliation and theology. “Personal spirituality” refers to the spiritual views shaped by life experiences that are unique to the individual and not necessarily related to one’s religion. “Integration and involvement with a spiritual community” reminds the clinician to assess for a patient’s membership and role in a religious organization or other group that provides spiritual support. “Ritualized practices and restrictions” are the behaviors and

| Table 30–1  |
| Pruyser’s Spiritual Dimensions |
| Spiritual Dimension | Negative, Less Healthy | Positive, More Healthy |
| Awareness of the Holy or God (sense of awe, reverence for that which is divine) | “When I hear the birds sing, they mock me; I see nothing sacred in nature—or anything else.” | “I feel very close to God now and am dependent on God’s help to face my death.” |
| Acceptance of God’s grace and steadfast love (experience of God as benevolent and unconditional in loving) | “I don’t need or deserve any help or kindness; I’ll handle things alone.” | “Thank you for caring for me so tenderly; you mirror God for me.” |
| Being repentant and responsible (openness to change, acceptance of responsibility for own feelings and behaviors) | “It’s not my fault I feel bitter.” | “How can I deal with my situation better?” |
| Faith (open, committed, and positive attitude toward life) | “There are some things in life I’d be afraid to do.” | “I’ve enjoyed every minute of life! I try anything new.” |
| Sense of providence (experience of God’s leadership and direction) | “Where has God been for me? He left me when I got sick.” | “I trust that God’s will will be done in my life and dying.” |
| Involvement in spiritual/religious community, and experience of communion | “Why should I have to ask for help from my church? They don’t bother to even call me!” | “I still feel connected to my church because I know that they are praying for me.” |
| Flexibility and commitment to living an ethical life | “There is no reason for me to still live. Let’s pull the plug here.” | “How I am choosing to die reflects my respect for the sacredness of my life; I have much to offer even while I’m in the process of dying.” |

lifestyle activities that influence one's health. “Implications for medical care” reminds the nurse to assess how spiritual beliefs and practices influence the patient's desire and participation in health care. “Terminal events planning” reminds the clinician to assess end-of-life concerns. These components of a spiritual assessment are most appropriate for use in palliative care settings; the mnemonic may be helpful for remembering them.

Anandarajah and Hight⁴⁶ developed a simpler mnemonic for remembering aspects of a spiritual assessment: HOPE. “H” reminds the clinician to assess for sources of hope, strength, comfort, meaning, peace, love, and connection. “O” refers to the patient's organized religion, while “P” stands for personal spirituality and practices. “E” prompts the clinician to assess for spirituality effects on medical care and end-of-life decisions. Again, the mnemonic may be stretched, but the parsimony of the assessment strategy is appreciated.

Similarly, Puchalski⁴⁷ proposed the mnemonic of FICA as a strategy for spiritual assessment. FICA prompts the clinician to assess to what faith and beliefs the patient has (F), how important or influential this faith is (I), what faith community or spiritual support group they participate in (C), and how the client would like the health/hospice care team to address their spiritual needs (A). This mnemonic may be easier to recall, and is appropriate for the initial or standard spiritual assessments.

Two other screening approaches that are very concise have been proposed by physicians Lo and colleagues,⁴⁸ who suggested the following questions for use in palliative care settings:

- Is faith/religion/spirituality important to you in this illness?
- Has faith been important to you at other times in your life?
- Do you have someone to talk to about religious matters?
- Would you like to explore religious matters with someone?
Striving to have an even more streamlined spiritual assessment, Matthews and colleagues59 proposed initial spiritual assessments could be limited to asking “Is your religion (or faith) helpful to you in handling your illness?” and “What can I do to support your faith or religious commitment?”

Case Study
Ms. B, a Patient With “Bone” Cancer

Ms. B, a 63-year-old African-American Pentecostal woman dying with “bone” cancer. Excerpts from an interview conducted by this author provide a partial picture of Ms. B’s spirituality:

If I ever wanted to be loved and appreciated, it is now! I just need to be with my grandkids, my kids all the time. I want to cook for them. I want to go places with them. I want to take some pictures. I just want to do it until that time comes . . . just the need to be wanted, not wanted because you this or you got that . . . a lot of love and laughter . . . just be needed, you know, for once, not because I am your momma, not because you have to, just be appreciative that we have each other . . .

I believe that there is a God, that Jesus died for you. I have hope, because a Man is up there. But I can’t go to church Sundays. With the pain, the pews are too hard, and I can’t get to the restrooms quick enough.

You never go ’til the Lord take you . . . and He says He “will never leave you or forsake you.” God allows this to be a testimony to other people about Jesus, how he died for us. There are things you can be doing. Say, we could be helping someone else. I speak with someone else about it and give God all the praise. I could sit here and say “Oh, I’m ready for the Lord to take me whenever He ready” and I can die. ’Cause every time I get ready—and at first I did. But right now I wanna express so much what He has done that I’m not ready to go until I’ve expressed it.

Nobody wants to go to Hell! Excuse me for sayin’ it like that. So, the first thing you want to do is get life right and go to Heaven. Even though I am in the Word and you say, “Lord, Lord, Lord,” maybe not to say you are going, but sometime, you feel like, “Am I already going to Hell?” or whatever! But you want to be as right as you can.

I wish the nurses would just stay for a few minutes and say “you gonna be okay, it’s in God’s hands.” That’s just in an instant, nursing spirituality! Or, having a nurse say, “Okay, I’m gonna put you on my prayer list.” But if the nurse is not a believer like me, it doesn’t help. You gotta have to have a certain feelin’ or vibe.

Assessment Using FICA

F (faith)—Pentecostal beliefs in God and Jesus. More specific beliefs include good behavior in present life means reward of Heaven in the after-life. God controls when she will die. In the meantime, she is to live her life as a “testimony” in praise of God.

I (import or influence)—This faith pervades her thinking and feeling, gives her hope, and allows joyfulness.

C (community)—Although she is used to attending Sunday services regularly at a local church, her terminal illness prevents it now. Her greatest desire is to receive and give love to her immediate family, including grandchildren (her spiritual community now).

A (address)—Would appreciate religiously like-minded nurses verbally reminding her of God’s providence and praying for her.

Nursing

Recent years have brought a number of spiritual care texts for nurses.1,2,26–28,50 These books generally include chapters on spiritual assessment. The nurse authors who have written about spiritual assessment are influenced by the writings of chaplains and pastoral counselors. However, they often go beyond a discussion of what dimensions to include in an assessment, to concrete suggestions about how to incorporate spiritual assessment into nursing care. Following is a review of what some nurse authors have suggested as spiritual dimensions for which to assess.

In a groundbreaking article, Stoll51 suggests four areas for spiritual assessment:

• The patient’s concept or God or deity
• Sources of hope and strength
• Religious practices
• The relationship between spiritual beliefs and health

Shelly52 posited that there are three fundamental or underlying spiritual needs that should guide how a nurse completes a spiritual assessment. These needs are: “(1) to be loved and to love in return, (2) to experience forgiveness and extend it to others, (3) to find meaning and purpose in life and hope for the future” (p. 30).

Carpenito’s53 questions for collecting data to make a nursing diagnoses of “spiritual distress” or “potential for enhanced spiritual well-being” reflect Stoll’s51 approach. In addition to questions that simply ascertain a patient’s religious affiliation, supportive clergy and helpful religious books as a source of strength and meaning, and questions that explore the link between spirituality and health are given (e.g., “What effect do you expect your illness (hospitalization) to have on your spiritual practices or beliefs?” “How can I help you maintain your spiritual strength during this illness?”). Furthermore, the North American Nursing Diagnosis Association (NANDA) criteria for spiritual distress can be used as indicators on an checklist-type assessment tool. Figure 30-1 provides an example of a spiritual self-assessment form.
**Spiritual Self-Assessment**

Often when people confront health challenges, they become more aware of their spirituality. For some, spiritual ways of thinking or living are especially helpful when health concerns emerge. For others, spiritual questions or doubts arise. This form will guide you to think about spiritual issues. After completing it, you may choose to keep it or give it to your nurse, who may want to share it with other health care professionals who will be caring for you.

NAME: _______________________________________

ROOM NUMBER: ___________

Place an “X” on the lines to show the answer that comes closest to describing your feelings.

**Recently, my spirits have been. . .**

- awful          low          okay          good          great

**In general, I see myself as. . .**

- not at all spiritual          a little spiritual          somewhat spiritual          fairly spiritual          very spiritual

**In general, I see myself as. . .**

- not at all religious          a little religious          somewhat religious          fairly religious          very religious

**What can a nurse do that would help to nurture or boost your spirits? (check all that apply)**

- spend quiet time with you
- have prayer with you
- help you meditate
- allow time and space for your private prayer or meditation
- let you know nurse(s) are praying privately for you
- read spiritually helpful literature to you
- bring art or music to you that nurtures your spirit
- let you know that you feel is spiritually helpful
- help you to stay connected to your spiritual community
- help you to observe religious practices
- listen to your thoughts about certain spiritual matters
- help you to remember how you have grown from previous difficult life experiences
- help you to tell your life story
- help you to face painful questions, doubts, or suffering
- just be with you, not necessarily talking with you
- just show a genuine and personal interest in you

**I would also like help in boosting my spirits from:**

- my friends and family
- other health care professionals
- my own clergy or spiritual mentor
- other clergy or spiritual leader
- a chaplain at this institution

**What would you like your nurse to know about your prayer or meditation beliefs and practices?**

**What literature, art, or music nurtures your spirit?**

**How can the nurse assist you with religious practices or fellowship?**

**What spiritual matters would you like to talk about most?**

**In what other ways can the nurse help to boost your spirits?**

**If there is anyone in particular you would like to meet with for spiritual fellowship, please so state. Or if there is someone you would like us to contact for you, please share what contact information you know:**

---

Dossey’s spiritual-assessment tool uses language that is less traditional (i.e., less overtly religious). This tool includes questions designed to assess meaning and purpose (“a person’s ability to seek meaning and fulfillment in life, manifest hope, and accept ambiguity and uncertainty”) and inner strength (“a person’s ability to manifest joy and recognize strengths, choices, goals, and faith”). The tool also contains questions that assess interconnections, or what Dossey describes as “a person’s positive self-concept, self-esteem, and sense of self; sense of belonging in the world with others; capacity to pursue personal interests; and ability to demonstrate love of self and self-forgiveness.” Selected questions from Dossey’s tool are found in Table 30–3, many in an adapted form.

While some spiritual care texts focus on how to conduct spiritual assessment interviews, some focus on paper-and-pencil type instruments for collecting information about spirituality. These instruments include some that are psychometrically tested and can be used for research purposes and some that were developed specifically for nurse or client spiritual self-assessment. An example of a nurse-developed...

self-assessment form for use with patients is presented in Figure 30-1.

Summary of Spiritual Assessment Models

The above summaries of various models for spiritual assessment identify spiritual dimensions that may be included in a spiritual assessment. Many of the dimensions identified in one model are observed (often using different language) in other models. The method necessary for completing the assessment generally requires the professional to make observations while asking questions, and listening for the patient's response. The vast majority of questions recommended for use in following such a model are open-ended. Several of the questions—indeed, the dimensions of spirituality—identified in this literature use “God language” or assume a patient will have belief in some transcendent divinity. The medical and nursing models that explicitly suggest assessment questions should address the linkage between spirituality and health, while the pastoral counseling models do not. All the models are developed by professionals who are influenced predominantly by Western, Judeo-Christian ways of thinking.

General Observations and Suggestions For Conducting a Spiritual Assessment

What Approach to Use

Whereas researchers often assess individuals’ spirituality quantitatively with “paper and pencil” questionnaires, health care professionals generally assess spirituality using qualitative methods (e.g., participant observations, semistructured interviews). However, it is possible to use questionnaires during the clinical spiritual-assessment process.1,12,14,40,52 This approach to conducting a spiritual assessment allows for identification, and possibly, measurement, of what one believes and how one behaves. This type of tool, however, should not “stand alone” in the process of spiritual assessment; rather, it can be the springboard for a more thorough assessment and deeper encounter with a patient, as appropriate. A quantitative tool should never replace human contact, instead, it should facilitate it. Although a quantitative spiritual self-assessment form provides an opportunity for health care teams to glean substantial information when screening for spiritual beliefs and practices, without spending any professional’s time, it also is limited by its mechanistic, rigid, and nonindividualized nature.6

Other approaches to spiritual assessment have been described in addition to the interview and questionnaire techniques. LeFavi and Wessels54 described how life reviews can become, in essence, spiritual assessments. Life reviews are especially valuable for persons who are dying, as they allow patients to make sense of and reconcile their life story. By doing a life review with a terminally ill patient, the nurse can assess many dimensions of spirituality (e.g., world views, commitments, missions, values) in a natural, noncontrived manner. Life reviews can be prompted by questions about the significant events, people, and challenges during the lifespan. A life review can also occur when inquiring about personal objects, pictures, or other memorabilia the patient wants to share.

Hodge51 identified several creative approaches to collecting information about client spirituality. Diagrammatic tools such as a spiritual genogram, spiritual family tree, or spiritual map could be drawn by the patient to describe and organize their spirituality. Having clients draw a spiritual timeline that includes significant books, experiences, events, and so forth, will also yield rich information. Another unusual approach involves sentence completion. For example, a client may fill in the blank of sentences like “My relation to God . . .” or “What I would really like to be . . .” or “When I feel overwhelmed . . .”

When to Assess

Dudley and colleagues34 found that 100 of 117 hospices surveyed acknowledged that they did spiritual assessments routinely. In practice, if spiritual assessment is a routine, it generally occurs during the initial intake assessment. However, some experts agree that spiritual assessment should be an ongoing process.1,45,51 The nurse does not complete a spiritual assessment simply by asking some questions about religion or spirituality during an intake interview. Instead, spiritual assessment should be ongoing throughout the nurse–patient relationship.

Stoll,51 recognizing the significance of timing when asking patients questions about spirituality, suggested that spiritual assessment be separated from a sexual assessment because both topics are so sensitive and intimate. However, both spiritual and sexual assessment should occur during the general assessment for the purposes of screening for problems. Several authors remind their readers that spiritual assessments can only be effectively completed if the health care professional has first established trust and rapport with the patient.6,51,57

Levels of Assessment

Many advocate a two-tiered approach to spiritual assessment.1,6,23,58 That is, a brief assessment for screening purposes is conducted when a patient enters a health care institution for palliative care. Matthews49 or Puchalski’s47 FICA guidelines work especially well for this screening. Ideally, what spiritual needs exist and how the palliative care team can care for these needs should be determined. Spiritual needs, however, are complex and often difficult to acknowledge, and more so, to describe with words. Furthermore, the patient may not yet feel comfortable divulging such intimate information to a nurse with whom rapport has not been established. General open-ended questions eliciting information about their faith, religiousness, or spiritual beliefs and practices are less upsetting than asking about “spiritual need” and can indirectly provide clues about needs. Kub and colleagues,38 in their research

---

**Figure 30-1**

Spiritual Assessment
with 114 terminally ill persons, found that a single question about the importance of religion to be more discriminating than a question about frequency of attendance at religious services.

If the screening assessment generates an impression that there are spiritual needs, then spiritual care can only be planned if further information is collected. The second tier of assessment allows for focused, in-depth assessment. For example, if a nurse observes a terminally ill patient’s spouse crying and stating, “Why does God have to take my sweetheart?,” then the nurse would want to understand further what factors are contributing to or may relieve this spiritual pain. To focus the assessment on the pertinent topic, the nurse would then ask questions that explore the spouse’s “why” questions, beliefs about misfortune, perceptions of God, and spiritual coping strategies.

Prefacing the Spiritual Assessment

Because spirituality and religiosity are sensitive and personal topics (as are most other topics nurses assess), it is polite for a nurse to preface a spiritual assessment with an acknowledgment of the sensitivity of the questions and an explanation for why such an assessment is necessary.1,45 For example, Mau gens49 suggested this preface:

Many people have strong spiritual or religious beliefs that shape their lives, including their health and experiences with illness. If you are comfortable talking about this topic, would you please share any of your beliefs and practices that you might want me to know as your physician (p. 12).

Such a preface undoubtedly will help both the patient and the clinician to feel at ease during the assessment.

Assessing Nonverbal Indicators of Spirituality

Although this discussion of spiritual assessment has thus far focused on how to frame a verbal question and allow a patient to verbalize a response, the nurse must remember that most communication occurs nonverbally. Hence, the nurse must assess the nonverbal communication and the environment of the patient. A chaplain mentor instructed the author to observe the ABCs of spiritual assessment (personal communication, John Pumphries, October 1986). The observer must assess the Affect, Behaviors, and Communication of the patient and think, “Are these elements congruent?” An incongruency between affect and words indicates an area requiring care and further assessment. To illustrate, a patient who responds to “How are you?” with “Fine”—but with an angry tone of voice and demeanor and avoidance of eye contact, is sending incongruent messages. Such a patient is likely angry.

Assessment of the patient’s environment can also provide clues about spiritual state.1,27 Are there religious objects on the bedside table? Are there religious paintings or crucifixes on the walls? Get-well cards or books with spiritual themes? Are there indicators that the patient has many friends and family providing love and a sense of community? Are the curtains closed and the bedspread pulled over the face? Does the patient appear agitated or angry? Many of the factors a palliative care nurse usually assesses will provide data for a spiritual assessment as well as the psychosocial assessment.

Language: Religious or Spiritual Words?

One barrier to spiritual assessment is the nurse’s fear of offending a nonreligious patient by using religious language. However, when one remembers the nonreligious nature of spirituality, this barrier disappears. Patients’ spirituality can be discussed without God language or reference to religion.

To know what language will not be offensive during a spiritual assessment, the nurse must remember two guidelines. First, the nurse can begin the assessment with questions that are general and unrelated to religious assumptions. For example, “What is giving you the strength to cope with your illness now?” or “What spiritual beliefs and practices are important to you as you cope with your illness?” Second, the nurse must listen for the language of the patient, and use the patient’s language when formulating more specific follow-up questions. If a patient responds to a question with “My faith and prayers help me,” then the nurse knows “faith” and “prayer” are words that will not offend this patient. If a patient states that the “Great Spirit guides,” then the sensitive nurse will not respond with, “Tell me how Jesus is your guide.”

Asking Questions

Because asking a patient questions is an integral part of most spiritual assessments, it is good to remember some of the basics of formulating good questions. Asking close-ended questions that allow for short factual or yes/no responses is helpful when a nurse truly has no time or ability for further assessment. Otherwise, to appreciate the uniqueness and complexity of an individual’s spirituality, the nurse must focus on asking open-ended questions. The best open-ended questions begin with how, what, when, who, or phrases like “Tell me about . . . ” Generally, questions beginning with “why” are not helpful; they are often mixed with a sense of threat or challenge (e.g., “Why do you believe that?”).

Listening to the Answers

Although it is easy to focus on and to worry about what to say during an assessment, the palliative care nurse must remember the importance of listening to the patient’s responses. Discussion of active listening is beyond the scope of this chapter, yet a few comments are in order. Remember that silence is appropriate when listening to a patient’s spiritual and sacred story. Listen for more than words; listen for symbols, listen for where the patient places energy, listen for emotion in addition
to cognitions. The nurse will do well to listen to his or her own inner response. This response will mirror the feelings of the patient.

**Overcoming the Time Barrier**

Health care professionals may believe that they do not have enough time to conduct a spiritual assessment. Indeed, Maugen and colleagues observed that completing his spiritual history with patients took about 10 to 15 minutes. Although this is much less time than Maugen and his colleagues expected it to take, it is still a considerable amount of time in today’s health care context. One response to this time barrier is to remember that spiritual assessment is a process that develops as the nurse gains the trust of a patient. It is ongoing. The nurse can accomplish the assessment during “clinical chatterings.” Furthermore, data for a spiritual assessment can be simultaneously collected with other assessments or during interventions (e.g., while bathing or completing bedtime care). And finally, it can be argued that nurses do not have time to not conduct a spiritual assessment, considering the fundamental and powerful nature of spirituality.

**Overcoming Personal Barriers**

Nurses can encounter personal barriers to conducting a spiritual assessment. These barriers can include feelings of embarrassment or insecurity about the topic, or can result from projection of unresolved and painful personal spiritual doubts or struggles. Every nurse has a personal philosophy or world view that influences his or her spiritual beliefs. These beliefs can color or blind the nurse’s assessment techniques and interpretation. Hence, an accurate and sensitive spiritual assessment requires that the nurse be spiritually self-aware. Nurses can increase their comfort with the topic and their awareness of their spiritual self if they ask themselves variations of the questions they anticipate asking patients. For example, “What gives my life meaning and purpose?” “How do my spiritual beliefs influence the way I relate to my own death?” “How do I love myself and forgive myself?”

**Assessing Impaired Patients**

Although verbal conversation is integral to a typical spiritual assessment, some terminally ill patients may not be able to speak, hear, or understand a verbal assessment. Patients who are unable to communicate verbally may feel unheard. In such situations, the nurse again must remember alternative sources of information. The nurse can consult with the family members and observe the patient’s environment and nonverbal communications. Alternative methods for “conversing” can also be used. For patients who can write, paper-and-pencil questionnaires can be very helpful. Always be patient and be unafraid of the tears that can follow. Questions that demonstrate concern for their innermost well-being may release their floodgates for tears.

**Assessing Children**

Several strategies can be employed to assess the spirituality of children. The clinician must remember, however, that building trust and rapport with children is essential to completing a helpful spiritual assessment. Children are especially capable of ascertaining an adult’s degree of authenticity. Children also are less likely to be offended by a question about religion. If a nurse creates a comfortable and nonjudgmental atmosphere in which a child can discuss spiritual topics, then the child will talk. Never underestimate the profoundness of a child’s spiritual experience, especially a dying child’s.

In addition to asking assessment questions verbally, the nurse can use play interviews, picture drawings, observations, and informal interviews. The nurse may need to be more creative in formulating questions if the child’s vocabulary is limited. For example, instead of asking the child about helpful religious rituals, the nurse may need to ask questions about what they do to get ready to sleep or what they do on weekends. When asking, “Does your mommy pray with you before you go to sleep?” or “What do you do on Sunday or Sabbath mornings?” the nurse can learn whether prayer or religious service attendance are a part of this child’s life. An assessment question that Sexson’s colleague Patricia Fosarelli found to be particularly helpful with 6- to 18-year-olds was: “If you could get God to answer one question, what one question would you ask God?”

Understanding the family’s spirituality is pivotal to understanding the child’s. Structured interviews or unstructured conversations with parents and even older siblings will inform the health care team about the child’s spirituality. Barnes and colleagues suggested the following questions as guides for assessing how a family’s spirituality affects illness experience:

- How does the family understand life’s purpose and meaning?
- How do they explain illness and suffering?
- How do they view the person in the context of the body, mind, soul, spirit, and so forth?
- How is the specific illness of the child explained?
- What treatments are necessary for the child?
- Who is the qualified person to address these various treatments for the various parts of the child’s healing?
- What is the outcome measurement that the family is using to measure successful treatment (good death)?

While assessing children, it is vital to consider their stage of cognitive and faith development. Questions must be framed in age-appropriate language (a 4-year-old will likely not understand what “spiritual belief” means!). Toddlers and preschoolers talk about their spirituality in very concrete terms, with an egocentric manner. School-aged and adolescent children should be addressed straightforwardly about how they see their illness. Inquiring about the cause of their illness is especially important, as many children view their illness and impending death as punishment.
Assessing Diverse Spiritualities

Spiritual assessment methods must be flexible enough to obtain valid data from persons with diverse spiritual and religious backgrounds. Although the questions and assumptions presented in this chapter will be helpful for assessing most patients living in Western, Euro-American cultures, they may not be for some patients who do not share these presuppositions. For example, some may believe it is wrong to discuss their inner spiritual turmoil as they face death and will refuse to fully engage in the process of spiritual assessment. (While some Buddhists and Hindus may believe they must be in a peaceful state to be reincarnated to a better state, African-American Christians may think it is sinful to express doubts or anger towards God.) Framing spiritual assessment in a positive tone may overcome this type of barrier (e.g., “Tell me about how you are at peace now.”) Others may assume they are void of spirituality and therefore decline any questions regarding their “spirituality.” This barrier to assessment can be overcome with questions that are void of such language (e.g., “What gives your life meaning?” or “How is your courage?”).

For patients who are religious, it is important to remember that no two members of a religious community or family are exactly alike. For example, one orthodoxly religious person may believe he should never consume any mind-altering drugs, such as morphine, while a less conservative member of the same denomination may understand that such drugs are a gracious Godly gift. Although having a cursory understanding of the world’s major religious traditions provides nurses with some framework for inquiry, remaining open to the variation of religious experience and expression is essential.

The Next Step: What To Do with a Spiritual Assessment

Making a Diagnosis

The North American Nursing Diagnosis Association (NANDA) includes “spiritual distress,” “risk for spiritual distress,” and “potential for enhanced spiritual well-being” as validated diagnoses. However, other language can be used to label a spiritual problem. For example, the NANDA diagnoses of “anxiety,” “impaired adjustment,” “ineffective family coping,” “dysfunctional grieving,” “fear,” “hopelessness,” “loneliness,” “social isolation,” “ineffective coping,” and “defensive coping” can also refer to what may be essentially spiritual problems. O’Brien’s list of potential spiritual problems begins to show the variety of diagnoses one patient could be given. Indeed, the NANDA primary diagnoses offer only a vague description; it is essential that the secondary or “related to” element of the NANDA diagnosis be determined. Without specific identification of a spiritual problem and its etiology, appropriate and effective interventions cannot be implemented.

Documentation

Although assessments of physiological phenomenon are readily documented in patient charts, assessments and diagnoses of spiritual problems are less frequently documented. However, for many reasons, spiritual assessments and care should be documented. These reasons include: (1) to facilitate the continuity of patient care among palliative care team members, and (2) to document for the monitoring purposes of accrediting bodies, researchers, quality management teams, and so forth.

Formats for documenting spiritual assessments and diagnoses can vary. Some institutions encourage staff to use SOAP (Subjective, Objective, Assessment, Plan) or similar formatting in progress notes shared by the multidisciplinary team. Others have developed quick and easy checklists for documenting spiritual and religious issues. Perhaps an assessment format that allows for both rapid documentation and optional narrative data is best. However, merely documenting one’s religious affiliation and whether one desires a referral to a spiritual care specialist certainly does not adequately indicate a patient’s spiritual status and need.

A summary of assessment forms created by professionals at hospices is reported by Dudley, Smith, and Millison. These researchers synthesized the spiritual assessment forms from 53 hospices, finding questions about religious affiliation and rituals, religious problems or barriers, and questions about spiritual (nonreligious) topics, that is, questions void of overly religious language. While Dudley and colleagues summarize the content of these forms, they do not review the format for documentation on these forms.

Conclusion

Spirituality is an elemental and pervading dimension for persons, especially those for whom death is imminent. Spiritual assessment is essential to effective and sensitive spiritual care. Indeed, spiritual assessment is the beginning of spiritual care. While the nurse questions a patient about spirituality, the nurse is simultaneously assisting the patient to reflect on the innermost and most important aspects of being human. The nurse is also indicating to the patient that grappling with spiritual issues is normal and valuable. The nurse also provides spiritual care during an assessment by being present and witnessing what is sacred for the patient.
REFERENCES

This chapter addresses the challenges of providing effective spiritual care to patients with terminal illness. The chapter is structured around the basic spiritual needs and is based on the certainty that there often is no one in a better position to provide spiritual care than the informed and committed nurse.

Definitions

There are many definitions of spirituality, religion, faith, and spiritual needs. For the purposes of this chapter, these terms are defined as follows:1,3–6

- **Religion**: An organized effort, usually involving ritual, dogma, and/or devotion, to manifest spirituality.
- **Faith**: The acceptance, without objective proof, of something, e.g., God.
- **Spirituality**: The incorporation of a transcendent dimension in life, usually, but not always, involving faith and religion.
- **Spiritual needs**: Human needs for transcendence that are addressed by most religions. The basic spiritual needs are meaning or purpose, hope, relatedness, forgiveness or acceptance, and transcendence.

Popular psychology or postmodern standards of political correctness often focus on spirituality without religion, faith, or God. However, in the real world of suffering, dying, and death, it is religion, faith, and God to which the majority of people turn.

Preparation

Providing spiritual care at the end of life can (and perhaps should) be a daunting task. Even the most academically and clinically prepared chaplain or counselor sometimes feels her
or his own inadequacy to intervene effectively with a person facing the end of life. While there is an increase in education on spiritual issues and care in health professions education, there often is a lack of practical content or practice in actually providing spiritual care. This lack of preparation, coupled with the enormity of death and the nurse’s personal doubts and uncertainties, may result in a reluctance to attempt to provide spiritual care—even when the need is apparent.6-8

Preparation to provide spiritual care includes clarification of goals, knowledge of spiritual needs, personal exploration, and willingness to apply knowledge of some basic interventions. Spiritual assessment and care should be introduced early in the course of care and reevaluated continuously. To facilitate a foundation of spiritual care, it is often essential for the nurse to first establish both a trusting relationship with the patient and good communication.

Clarification of Goals

The primary goal of spiritual care is to increase the opportunity for reconciliation with God (or a higher power) and self. This goal is based on the ideas that (1) life does indeed come from God, and (2) for many people, the process of living includes some degree of felt separation from God and faith. In the Western world, approximately 95% of people claim to believe in God, and worldwide about 85% of people claim to be religious,5-11 so this goal would logically be as basic to persons with terminal illness as would relieving pain, dyspnea, and other symptoms. More specific goals of palliative care are clearly related to the spiritual needs, such as decreasing the sense of meaningfulness, purposelessness, or hopelessness or increasing a sense of relatedness, forgiveness, or acceptance. In terms of nursing diagnoses, the goal would likely be relieving spiritual distress, but the previously stated goals are more specific and function as etiologies (e.g., “spiritual distress related to hopelessness”). Note that the goal in spiritual care is not to provide one’s own answers to ultimate questions or for the patient to achieve a particular belief. Most of the interventions and goals given here can apply to persons of any faith, or even to persons of no faith.

Knowledge of Spiritual Needs

Each of the spiritual needs is discussed below. Hope is also discussed more extensively in Chapter 26.

Meaning includes the reason for an event or events, the purpose of life, and the belief in a primary force in life. Meaning may be sought in a review of life achievements, in a review of relationships, in a moral or spiritual search, especially of life as it was lived, and in an effort to discern the meaning of dying, of human existence, of suffering, and of the remaining days of life.3,4 Hope is for the “expectation of a good that is yet to be.”5,12 There often is hope to not die, and, failing that, hope to live and die in a way perceived to be good.4 In the struggle of terminal illness, spiritual hope may be distilled into achieving the purpose of life: reconciliation with God, with self, and with others.1

Relatedness for Christians, Jews, and Muslims is to God; for Hindus and Buddhists, relatedness may also be to (1) God or a god or (2) a system of spiritual faith or belief. Here, God is defined as supreme or ultimate reality, infinite, eternal, universal, all-knowing, and Being Itself. Relatedness for persons of any faith may also include relatedness to a religion or faith community.

Forgiveness by God is often seen in the West as a concept of Christianity, Judaism, or Islam. However, the Buddhist and Hindu concepts of karma and transmigration of souls also directly address forgiveness or at least another chance to rectify mistakes. Acceptance is related to forgiveness and meets the underlying need to deal with mistakes or misfortune in life.1

Transcendence is that which takes one beyond self and suffering—or attachment to self and suffering—beyond death. Transcendence can occur as a result of meeting other spiritual needs or as grace or manifestation of the divine, and thus may be seen as the outcome of spiritual needs or as the ultimate spiritual need.1,13

Understanding or working toward understanding these needs provides a framework for understanding and intervening in spiritual distress. Not every person fits neatly into spiritual distress related to one or more of these (unmet) needs, but at a minimum, these needs give nurses and others a place to start looking in a mindful manner at the spiritual dimension in terminal illness.

Personal Exploration

Working in palliative care is emotionally and spiritually challenging. Regardless of one’s profession or role, those who work in palliative care operate, at least some of the time, at the edge of human existence and are often confronted by deep human suffering in all spheres of being (physical, psychological, social, and spiritual). To work gracefully and effectively in these circumstances, it is essential to explore one’s own losses, grief, and fears. Such an exploration brings the practitioner face-to-face with existential challenges, such as the inevitability and finality of death, the isolation and separateness that are part of every life, and, if the truth be known, the inability to truly “deal with it.” Sooner or later, personal exploration may then evolve into a spiritual search. Here again, though, the searcher may be found wanting. One may then look to the refuge intrinsic in every major faith. For here is the truth: Few of us in palliative care would presume to think “I can do the whole of the physical care”—in terms of the care for a particular patient, much less in terms of developing and putting into practice the theory and principles of palliative care! Few of us (clergy included) should then presume to think “I can do the
whole of the spiritual care”—either in terms of the care for a particular patient, much less in terms of confronting and understanding the enormity of human existence, including death.

Personal spiritual exploration may lead to exploration of spiritual and religious resources such as church, synagogue, mosque, or temple. Of course, there are those who are spiritually well-grounded and able to provide quality spiritual care even though they do not participate in religious activities. However, a greater number do find that participation in spiritually based activities, specifically in religious activities where “universal values” are served by tradition, increases the capacity to provide spiritual care.3,24

In their seminal study of the spiritual practices of oncology nurses, Taylor, Amenta, and Highfield15 found that 65% of oncology nurses surveyed attended religious services “frequently,” ranging from one to three times per month (21%) to weekly or more often (44%). Both nurses and their patients benefit from the strongest possible spiritual foundation.

Basic Spiritual Care Interventions:
“Watching With” and Prayer

Interventions related to basic spiritual needs are presented below; however, it is vital to keep in mind that the critical and most fundamental intervention is to remain present (to “watch through the night”) in the face of suffering, fear, despair, and all the physical/emotional/social/spiritual trials of dying.16 Being present on a consistent basis through the process of dying is primary spiritual care and addresses the most fundamental spiritual need—the need for transcendence. Granted, neither the patient nor the nurse may necessarily feel transcendent. Still, there is an undeniable element of transcendence in the willingness to go beyond self and suffering, and there is an undeniable need for this presence. The Bible presents the need for this presence in stark and universal terms: “My soul is very sorrowful, even to death; remain here, and watch with me” (Matthew 26:38).17 And so the nurse and others working in palliative and hospice care have this opportunity to provide primary spiritual care that does not require understanding, answers, acceptance, or conquering—all that is required is to “watch with me.”

A second, fundamental intervention is prayer. While many authors note prayer as an intervention, few are able to say how one implements this basic aspect of care (except as an expression of [usually Christian] spiritual practice). Here then are some of the author’s thoughts and experiences in prayer.

For many, prayer is a deeply personal issue. For a non-clergyperson, moving into the dimension of prayer may be a difficult step. Knowing that somehow prayer would help, there may be reluctance to (1) take the risk of spiritual rejection or (2) be put on the spot as a provider of frank spiritual care when there is certain knowledge of one’s personal spiritual inadequacies. Yet we know prayer can be comforting, cleansing, and transcendent. The first one is the hardest.

A 17-Year-Old Girl with Bronchitis

I work mostly in primary care with medically indigent refugees and immigrants. Not long ago I walked into an exam room where a 17-year-old Mexican girl sat, ravaged by a 5-year history of central nervous system tumor, seizures, strokes, surgeries, and radiation. Her mother sat a few feet away, silent, dignified, very tired, and full of pain. The girl had bronchitis, and I prescribed the appropriate treatment. My anxiety about prayer fell away (Why was I ever concerned about myself?) and I asked the Mom if we could pray. She said yes, and we all held hands and I led the girl, Mom, translator, and nursing student in prayer. I thanked God for the Mom, the girl, for the doctors and nurses treating the girl, and for them coming to our clinic; I prayed for healing of body and spirit and for the strength to accept God’s will.

So the first step is to see what is in front of one’s eyes and forget about oneself. Invitations to prayer come from the heart. The words might include, “Could I say a prayer with you or for you?” or “Are you a praying person, because this feels like a time for a prayer.” A noted physician and ethicist suggests that prayer may be gently introduced into a patient-care encounter by asking, “Would it be okay if we have a prayer? Even if it won’t help you, it will help me.”18 Readers will readily see that such a request also is likely to have a salutary effect on the relationship between the patient and provider. Other interventions are discussed below.

Interventions: Spiritual Needs, Problems, and Practices

Each of the spiritual needs is examined below, including a discussion of the need, manifestations of the unmet need, and interventions to help in meeting the need. In actual practice, there often is overlap among problems resulting from the unmet needs. This may include needs that are never assessed and needs that are met or neglected to varying degrees. As with other frameworks for practice, patients and families do not always fit neatly into certain categories. In general, unmet spiritual needs may be expressed by direct statements of hopelessness, meaningless, despair, guilt, and so on. Indirect expressions of unmet spiritual needs may include anxiety, sadness/depression, fear, irritation, loneliness, and anger.4 (See Chapter 30, Spiritual Assessment, for discussion of these signs.)

Meaning

For many people, serious questions about the meaning of life typically arise in the late teen years and into the early 20s. After that, these questions may be set aside or put into the
background, as work, relationships, raising children, and other life demands take precedence over philosophical pursuits. Often, decisions are made and paths taken without regard to any component of meaning or other such concerns. In life, one does what one must do. Later, as the end of life approaches, questions of meaning may again arise.

Few people go through the process of terminal illness without experiencing some form of life review. It is important to note that those whose physical symptoms are unmanaged without remission are often unable to address meaning and other spiritual issues because they are more likely to focus only on physical needs and suffering. That life review, whether conscious or unconscious, brings forth the question of, "What did my life mean and how well did I live it?" If the answer is, "My life was full of meaning and I lived it well," then meaning is more likely to be found in the last days, and those days are more likely to be lived well. If, on the other hand, the answer is, "My life had little meaning and I did not live it well," then meaning is less likely to be found in the last days, and those days are less likely to be lived well. The old adage of palliative care is again illustrated: without skilled intervention, most people die in a manner very similar to that of the rest of their lives.

However, there are those whose lives are characterized by spiritual emptiness and pain who then find meaning in life even as it draws to an end. For these, terminal illness may serve as a motivation to reach beyond self and suffering. To participate in such a process of spiritual growth is a privilege. Much of this chapter is focused on promoting this growth. A sense of meaninglessness in life as a whole may be first addressed by assisting the patient through a mindful life review.

Previously it was noted that unless physical problems are overwhelming, almost everyone who is dying goes through some sort of life review. The problem with such life reviews is that many times they are undertaken in a time of despair, and/or they tend to focus on the negative. More importantly, these reviews are unproductive. This author is probably not alone in the search for meaning in life as it has been lived is facilitated by asking the patient the very serious question, "If you had your life to live over again, what would you like to be different and what would you like to be the same?" In certain close and therapeutic relationships, this question can serve as a framework for the therapeutic aspect of the relationship. In a home care setting, for example, the question can be rephrased to address the various dimensions of a person's life (e.g., "In terms of your spiritual life, what would you . . .?" or "In terms of relationships . . .").

This "If you had your life to live over" question is often painful for the patient. Who among us does not have painful memories and regrets? But the pain is not caused by the question. Most likely the pain was already there, perhaps suppressed or perhaps just hidden from others. This question serves not only to look at the past and the meaning of a person's life, but also to present circumstances, the future, and what meaning might emerge.

The meaning of dying, suffering, and death are difficult, if not impossible to understand in terms of psychological explanation. These meanings can be addressed by questions such as, "What does it mean to you that this (dying or suffering) is happening?" This is a very serious question, and often gets serious answers. The suffering of the dying is not in any way an academic issue. The questions of, "Why me; why am I suffering; why am I dying?" are not ones for the nurse or others to answer. Rather, they are questions to which the response is to stay with the patient in her or his time of questioning and doubt. Many times, providing an answer only stifles the patient's exploration of the suffering and its meaning.

Every religion acknowledges and deals with the problem of suffering and death, and every religion is rich in examples of compassionate reaction to human suffering and death.

On Him let man meditate
Always, for then at the last hour
Of going hence from his body he will be strong
In the strength of this yoga, faithfully followed:
The mind is firm, and the heart
So full, it hardly knows its love.
—The Way to Eternal Brahman (Bhagavad-Gita)
Buddha's compassion is equal toward all people; but it is expressed with special care toward those, who, because of their ignorance, have heavier burdens of evil and suffering to bear.
—Buddha's Relief and Salvation for Us

"Mindful life review" means that the nurse or other staff suggests to the patient a deliberate and thoughtful verbal or written review of the patient's life, including relationships, achievements, failures, high points, low points, and so on. It is essential to understand that such a review is not a one-time activity, or something that occurs early in the relationship, but, rather, is one valued aspect of an ongoing nurse–patient relationship. For example, in a home care setting, the nurse might ask the patient to think about one important relationship that was or is positive and one that was or is less positive and to talk about those during the next home visit. At that visit, the nurse listens to what the patient says about the relationships, helps the patient explore them in greater depth, and helps identify ways in which the relationships might be redefined or viewed in a more realistic manner. Specific to spiritual matters and meaning, the nurse might ask the patient to think about something that has been full of meaning in the patient's life and, conversely, to think of something important that seemed meaningless or possessed negative meaning. The interventions are contained (1) in the patient's explanation of the issue or issues and (2) in the nurse's help to the patient in breaking out of repetitious thinking about the issue(s).

The search for meaning in life as it has been lived is facilitated by asking the patient the very serious question, "If you had your life to live over again, what would you like to be different and what would you like to be the same?" In certain close and therapeutic relationships, this question can serve as a framework for the therapeutic aspect of the relationship. In a home care setting, for example, the question can be rephrased to address the various dimensions of a person's life (e.g., "In terms of your spiritual life, what would you . . .?" or "In terms of relationships . . .").
I lift up my eyes to the hills. From whence does my help come? My help comes from the Lord, who made heaven and earth. He will not let your foot be moved, he who keeps you will not slumber. Behold, he who keeps Israel will neither slumber nor sleep. The Lord is your keeper; the Lord is your shade on your right hand. The sun shall not smite you by day, nor the moon by night. The Lord will keep you from all evil; he will keep your life, The Lord will keep your going out and your coming in from this time forth and for evermore.

—Psalm 121

Let not your hearts be troubled; believe in God, believe also in me. In my Father's house are many rooms; if it were not so, would I have told you that I go to prepare a place for you? And when I go and prepare a place for you, I will come again and take you to myself, that where I am you may be also. And you know the way where I am going.

—John 14:1–4

We heard his prayer and relieved his affliction. We restored to him his family and as many more with them: a blessing from Ourself and an admonition to worshipers.

—The Prophets

For many patients, help in finding and discussing passages from the sacred books of their own faiths may provide the best kind of answer to the question of the meaning of suffering and death. Of course, worship, ritual, prayer, and meditation are, or should be, part of the spiritual care milieu. Encouraging these is important, both for the patient's and family's life, and for promoting their presence in the life of the institution or organization in which one practices.

Most people confront the questions of meaning in life, suffering, and death from the point of view of their own existence. The human condition and its tendency to isolation leads to the idea that the feelings of meaningless, emptiness, and brokenness are unique to the one who is experiencing them. Of course these feelings are not unique! Exploration of how and why a person feels this way, coupled with a gentle reminder that the person is not alone in these feelings may be helpful. Here again, the questions and responses lead to the realms of spirituality and religion. For Christian and Jewish patients, certain Psalms (e.g., 6, 32, 38, 39, 41, 51, 61, 69, 88, 91, 102, 103, 130, and 143) are especially appropriate to read and discuss with respect to the meaning of suffering. Better yet, find out from the patient what scripture is most meaningful to her or him.

Contemplating and exploring the questions of meaning in life, suffering, and death noted above is likely to lead to other questions about forgiveness, acceptance, punishment, and even transcendence. Once again the questions and responses lead to the realms of spirituality and religion. These questions may lead also to questions and exploration of the meaning or purpose of the remaining days of life and to the question of what might be done to make the most of that time, both in the present and in the future. As noted earlier, the primary goal of spiritual care is to increase the opportunity for reconciliation with God (or a higher power) and self. It is not overly directive to suggest that a person looking at a very limited future on earth might consider whether one or all three of these reconciliations are worth serious contemplation for at least part of future direction.

Finding meaning in the process of dying is largely dependent upon the degree to which the patient finds some meaning in his or her life when reviewing it. Looking at the question of what one would like to have done differently in life is critical to a fulsome review of life—the good and the bad. Bringing the whole of one's life into consciousness and applying sacred literature, worship, and prayer to the process of dying may lead directly to increased meaning in the present and future (Table 31–1). “What our patients need is unconditional faith in unconditional meaning.”

**Hope**

Although Chapter 26 is devoted to hope, hope in a solely spiritual sense is also discussed here. Themes or “universal components of hope” include finding meaning through faith or spirituality, having affirming relationships, relying on inner resources, living everyday life, and anticipating survival. Not all these may be achieved in the context of terminal illness—at least in a physical sense—but all are applicable to many people going through a terminal illness. Despite the realities and challenges of terminal illness, there may be much to hope for: to live another day, for relief from suffering, for a greater understanding of life, for a good death with dignity, for a healed relationship, to see a loved one, to not die at all, or simply to be able to go through the ordeal of dying.
Hope in terminal illness can be addressed directly by asking, “What do you hope for . . . in this illness (or situation)? . . . from others? . . . at this point in your life? . . . in just this day? . . . in or for yourself? . . . in your faith (or religion or spiritual life)? What would you like to hope for?” These questions are powerful at a time like this and can facilitate expression of deep feelings and issues. What a question to ask and issue to raise—hope in terminal illness! The answers to the questions are often a mix of hope and resignation. The critical point is to directly bring up the concept of hope for exploration and discussion.

Hope in this context includes hope for reconciliation with God and self. This does not, in any way, diminish the importance of hope in relation to other matters, especially hope to heal relationships with other people. Hearkening back to the earlier discussion of meaning and reconciliation, one quickly sees that making progress toward reconciliation will have a direct impact on the presence or absence of hope, whether spiritual or otherwise—or more commonly, on the waxing and waning of hope.

**CASE STUDY**

**Mrs. P, a Patient with Cervical Cancer**

Mrs. P had a terribly difficult life. She grew up poor, and in her middle years survived war, torture, forced labor, and being a refugee several times over. When first admitted to hospice, she was an alcoholic and abusive to her children. She lived in a run-down one-bedroom apartment with her husband (also an alcoholic), a son who was a gangster, another son with Down syndrome, and a 12-year-old daughter, who was the primary caregiver. Mrs. P spent most of her days and nights lying on a small couch in the apartment’s living room.

She had cervical cancer, with many complications. Symptom and disease management were complicated by her alcoholism, poverty, and limited English proficiency. Overall, and considering the circumstances, her symptoms were relatively well managed.

It was clear to all concerned that Mrs. P was spiritually bereft and without hope. Using both Buddhist and Christian translators, the hospice team tried counseling to address hope and other spiritual issues in several different ways. Although she was nominally Buddhist, she refused offers of transportation to the temple. On several occasions, she accepted gifts of objects sacred to Buddhists, but after a few days would put them away. Several Christian missionaries visited on a regular basis and, although she did not resist these visits, neither did she respond to them. Everything tried seemed to fail. She did, however, show appreciation for efforts to care for her and her family.

The only thing that seemed to affect her was when one day a nursing student knelt unbidden beside Mrs. P’s couch and prayed. Although Mrs. P understood little of the prayer, tears began to run down her cheeks as the young woman prayed. Afterward, Mrs. P whispered, “Thank you.”

As far as I know, this patient’s spiritual needs were never met, and I never saw any evidence of hope or reconciliation. So what is the point of this case study? Where are the effective interventions and the insights? Unfortunately they are not to be found—except that those of us who tried to be effective and insightful never gave up. Though none of the caregivers, the patient, or the family ever experienced much in the way of transcendence, in retrospect, there were 2 years of transcending the desire to quit.

The week before she died, I went out of town for a conference. I returned late Sunday. On Monday, I left for work early so I could see Mrs. P first. I walked into her apartment and at that moment, she died.

There are two great hopes offered to the dying and to all others by faith and religion:

1. The hope to live more fully and deeply—after all these years, in so many cases, of superficiality. All the major faiths provide clear guidelines for living in connection to faith and God or whatever one calls ultimate reality. All the major faiths say without equivocation that living in this manner brings the greatest possible fulfillment.

2. The hope for a life beyond this one. All the major world religions have definitive and hopeful beliefs in outcome, that is, in what happens or can happen after death. In fact, it is only religious belief that offers any possibilities about the future after death—other than the recyclable nature of our basic molecule, carbon.

Increasing or reaching these two great hopes begins with exploration of hope and hopelessness, and thence to sources of knowledge and insight into hope and truth. After looking at what hope and hopelessness exists, one may then in partnership with the patient begin looking at the patient’s faith tradition for hope that may be found there (Table 31–2).

Die, and you win heaven. Conquer and you enjoy the earth. Stand up now, son of Kunti, and resolve to fight.

---

**Table 31–2**

**Notes on Hope: The Patient, Family, and Nurse**

- Understand common hopes in the process of dying.
- Understand that two great hopes are offered by faith and religion: (1) to live fully and deeply, and (2) to expect life after death.
- Ask direct questions about hope, and explicate the presence or absence of hope.
- Integrate the sacred into the process of dying: prayer, reading, worship, and ritual.
- The nurse and others faithfully “watch through the night,” whether the patient or others have or do not have hope.
Realize that pleasure and pain, gain and loss, victory and defeat, are all one and the same: then go into battle. Do this and you cannot commit any sin.
—The Yoga of Knowledge (Bhagavad-Gita)\textsuperscript{20}

Relatedness

Relatedness in the spiritual sense is to faith, religion, and especially to God (or with whatever represents God), or to all three. Existentially, of course, many people feel very much alone in life and in the universe. The same holds true in terms of faith and/or religion.\textsuperscript{4} Just as the quest for meaning in life may have been put into the background, so may a quest for spiritual growth or for a deep connection with faith been put away. In some people, there is a deep feeling of having been failed by their faith and the faith community. The result of any or all of these is a sense of isolation from faith and from God or anything greater than this—this life, this inadequacy, this suffering, this transience. It is possible, and even not unusual to spend an entire lifetime trying to avoid dealing with existential and spiritual isolation.

Terminal illness tends to bring everything into sharper focus, and loneliness or meaninglessness that once seemed a bearable part of life may come to the forefront after years of suppression. The need for reconciliation or reconnection then becomes a driving force in the remaining days of life.

For most people of most faiths, the reconnection is to God. Whether referred to as Yahweh, God, Lord, or Allah, the God of Judaism, Christianity, and Islam is clearly explicated. Contrary to some conceptions of Hinduism, Hindus also believe in “One God, who can be understood and worshipped in many different forms.”\textsuperscript{24} In the Buddhist canon, relatedness is to the faith and philosophy. However, in practice, many Buddhists believe in a divine “force” or “being,” as expressed by the Buddha or existing as mystery and never explicated, but never denied in the teachings of the Buddha. From a psychological perspective, Carl Jung\textsuperscript{25} wrote with deep insight that the presence or acknowledgment of God among virtually all peoples of all religions through all times is evidence of God as a universal archetype or “living psychic force” and that the imprint of God in this manner “presupposes an imprinter.”

Given the incomplete and unenlightened nature of most of us, the primary way then to relatedness to or reconciliation with God is through religion and religious practice, including prayer, ritual, and worship. Ritual and worship are sometimes constrained, not so much by patient circumstances, but more by a lack of imagination on the part of regular sources of spiritual care. Thus, a church may not think to bring communion to the patient’s home, nor a temple to offer an opportunity to give alms to monks. The nurse or other provider can then act as an advocate for the patient by giving direct suggestions to the source of spiritual care. The nurse may also in some cases provide/participate in ritual. Of course, the presence of chap-\ldots
Forgiveness or Acceptance

Every religion has rules and sanctions related to how one lives in the world and how one practices the religion and its precepts. Every religion also acknowledges that humans fail to fully follow its rules and has provisions for such failures. In Hinduism and Buddhism, there are cycles of birth and rebirth based on actions in life (we are born to be healed). Although sin and attendant suffering are issues in these faiths, the focus of practicing the faiths is more on acceptance of self and suffering than on forgiveness. In Judaism, Christianity, and Islam there is the concept of forgiveness of sins.

To those who avoid the grossest sins and indecencies and commit only small offenses, your Lord will show abundant mercy. He knew you well when He created you of earth and when you were hidden in your mother’s wombs. Do not pretend to purity; He knows best those who guard themselves against evil.

—The Star

Psychologically, there may also be a need for forgiveness or acceptance of self. While routinely considered psychological issues, the need for self-forgiveness or self-acceptance may be tied to spiritual issues. In most cases, a sense of forgiveness or acceptance from either source (self or God) promotes the same from the other source.

Earlier, it was suggested that persons who are dying (and others) benefit from a mindful life review that includes both the “good” and the “bad” of the person’s life. Such a review inevitably leads to consideration of mistakes and/or unfortunate aspects of life. In many cases, there is at least some crumbling of defenses that functioned to hide certain painful aspects of life. Guilt is often the result, and it does not seem to matter whether the issue is something one did, such as a pattern of dishonesty, or if the issue is something that was experienced, such as growing up in an alcoholic family.

In the discussion of meaning, it was strongly suggested that the nurse employ the question, “If you had your life to live over again, what would you like to be different?” Clearly this question has direct application to the issue of forgiveness or acceptance. In the sort of deep and open relationship for which we strive in hospice and palliative care, this question often brings a strong response that may include a deep sense of regret or guilt. The question is really less of an assessment question than a starting point in a search for understanding and ultimately, forgiveness or acceptance (Table 31–4).

### Table 31–4

**Notes on Forgiveness or Acceptance: The Patient, Family, and Nurse**

- Understand the universality of sin, regret, and guilt.
- Not all guilt is related to the patient’s own doing.
- A life review almost always includes elements of the need for forgiveness or acceptance.
- Forgiveness and/or acceptance cannot be conferred by another, but the practice of mercy is a manifestation of forgiveness and acceptance.
- Integrate the sacred into the process of dying: prayer, reading, worship, and ritual.

---

Mrs. K., a Patient with Lung Cancer (the author’s mother)

Mrs. K. was dying from small cell carcinoma of the lung, with metastases to brain and bone. Treatment of the primary tumor and metastases included several courses of chemotherapy and radiation, both initiated and discontinued at appropriate times. Her primary symptoms were pain, fatigue, and nausea, all of which were well managed. She lived in a cottage behind the house where her son, daughter-in-law, and grandson lived. She enjoyed warm, supportive relationships with her family and others. She had no financial worries.

However, there was an element of low-level unhappiness and vague suffering through much of her illness. In a series of difficult interactions in which she and her son struggled to share their deepest feelings about her life and their relationship, she was finally able to say truthfully how she saw herself: “I’m naked and ugly and skinny. I’m lying in the bottom of a pit and it’s dirty and there are cigarette butts all around me.” Her son responded, “That’s not you—it’s what you feel like, but it’s not you.” She replied by begging for forgiveness for the mistakes she had made. Her son told her not to beg, that he forgave her and hoped that she forgave him, but more importantly, God forgave her.

She felt a great sense of peace afterward and began making detailed plans for her funeral. Her choices of scripture and hymns were a lovely expression of her past and her future. She spent many hours talking about what these passages and hymns meant to her.

The role of the nurse or chaplain or other caregivers is not to try to confer forgiveness or acceptance or to convince a patient that her or his faith offers forgiveness. It is possible, however, to manifest forgiveness and acceptance through providing consistent loving care, and thereby hold out to the patient the possibility that forgiveness and acceptance are possible. This practice of mercy is a high ethical demand in nursing and related fields and may be seen in terms of beneficence, fidelity, and justice. Similarly to the care in other spiritual issues, the nurse may help connect the patient to the sacred and the practice of faith: prayer (in this case for forgiveness or acceptance), reading (especially passages that acknowledge the reality of sin and forgiveness), and worship and ritual (especially ritual related to purification).
Transcendence

Transcendence is a quality of faith or spirituality that allows one to move beyond, to “transcend” what is given or presented in experience—in this case, the suffering and despair so often inherent in dying.1

Beyond, beyond
Beyond that beyond
Beyond the Beyond.
—Buddhist mantra

Transcendence is certainly more than resignation and is also more than what many think of as acceptance in the process of dying. At its highest level, there is an element of beauty or spiritual elevation in transcendence. At its most basic level, transcendence is the means by which one finds meaning “retroactively . . . even in a wasted life.” Even more than the need for forgiveness or acceptance, transcendence resists being conferred by others or problem-solving approaches. “Man is never helped in his suffering by what he thinks of for himself; only suprahuman, revealed truth lifts him out of his distress.”

Transcendence can occur in at least one of two ways:

1. The other spiritual needs are met and transcendence then is an outcome.
2. Transcendence occurs through grace, or as Jung would state it, through “suprahuman, revealed truth,” and thus may exist independently of other spiritual needs; or of work, actions, or human interventions. In this latter case, we see that through transcendence, all other spiritual needs are met.

Transcendence is a profound issue that cannot be approached from a problem-solving perspective, and there are no specific interventions that lead to transcendence. One “watches” with the patient and practices mercy and is grateful when transcendence occurs.

It is well worth considering that there may be elements of transcendence in the practice of hospice and palliative care. Those who practice in this field operate at the edge of human existence. Sometimes we see that the practice also has elements of our own denial and fear of death, but sometimes, in the deep heart of the night, we transcend our own denials and fears and become—if only for a moment—a manifestation of the transcendent beauty seen when there is reconciliation with God, with self, and with others (Table 31–5).

Table 31–5
Notes on Transcendence: The Patient, Family, and Nurse

- Integration of the sacred into the process of dying may lead to transcendence.
- Transcendence is beyond human intervention.
- Take note of the times when transcendence occurs in the practice of hospice and palliative care.

General Notes on Providing Spiritual Care

The following are general suggestions for providing spiritual care. Not all are applicable in every case, and some may never be applicable to a particular patient or in a particular person’s practice. They are offered here as ideas or suggestions that readers may add to in the effort to provide quality spiritual care.

- Remember that there often is nobody better placed or better qualified than the nurse to provide spiritual care.
- Patients and families often are reluctant to raise spiritual issues, but many respond positively to health professionals, who are “able to step beyond rigid professional boundaries.”
- Integration of the sacred into the process of dying should probably always be attempted, even if only in the nurse’s life and the institution’s milieu.
- There are situations in which the patient cannot physically tolerate going to a place of worship for a complete service, but can stay for a limited time. When this is the case, the patient may need help to choose which part of the service to attend, and the place of worship may need help in accommodating the patient’s participation in the service. In some cases, the patient may need additional medication or portable equipment to make it through even part of the service.
- When, because of physical or other limitations, it becomes difficult for the patient to visit a place of worship, home or hospital visits from clergy should be considered. It is sometimes necessary for the nurse or other staff to make repeated appeals to the patient’s clergy for such visits.
- Other religious activities that can take place at home or hospital include prayer, ritual, reading, and other spiritually oriented activities, including music. Music can be helpful to the patient and others, and might be provided by a few choir members coming to the home or by tapes or CDs of religious music.
- The presence of a religious book in the patient’s home or room provides the opportunity for the nurse to pick up the book and discuss it with the patient. It is helpful for the nurse to actually take the book in hand when initiating discussion. It also is helpful to ask the patient to read aloud passages that are most important to her or him. If the patient is unable to read, the nurse or other caregiver can do the reading. (If the book is the Koran, the nurse should wash his or her hands before taking it in hand.)
• There is an understandable tendency for people to want to do things for the person who is dying. It is important to encourage the person who is dying to also do things for others. Creating or affirming memories and leaving a legacy is suggested by Lynn and Harrold.27 This might include the patient giving a copy of the holy book of her or his faith to a loved one (e.g., a grandchild), planning the funeral service, making a point of reconciling with others, spending time to consider a mindful good-bye, and other means of making connection with others, including teaching the nurse what matters spiritually.

• Everyone dies, and while it is of no help to trivialize an individual’s experience by pointing this out in a heedless manner, it may be helpful to carefully introduce the universality of the experience—especially the fact that many others have struggled with pain, fear, guilt, and other core issues in dying and death. All the major religions address the universality of death and suffering.

• Recall that hospice and palliative care emerged, in part, as humane responses to the increasingly technological nature of dying and death in the modern world. The serious question, “How can the spiritual and sacred become more a part of the process,” arises both in terms of a particular patient and in terms of institutions.

• It is also important to always remember that key concepts in palliative care are respect for the person and protection of individual differences. Some patients and families may not want spiritual care, and these preferences should be respected.

• Prayer, invited and offered from the heart, is a powerful means of caring for the patient, family, and nurse.

And finally, the practice of mercy—of watching through the night—is central to hospice and palliative care and to the practice of every faith.

REFERENCES

Meaning in Illness

I cannot understand God's timing . . . there's so much left for me to do. I've tried asking for more time . . . it seems that's not going to be granted, but I have great faith that God knows more than I do and that He's watching over me.—Cancer patient

In the driest whitest stretch
Of pain's infinite desert
I lost my sanity
And found this rose

—Galal al-Din Rumi; Persia, 1207–1273

Key Points
- Finding meaning in illness is an important issue when facing the end of life.
- The process of finding meaning in illness involves a journey through sometimes very difficult transitions.
- A terminal illness can greatly impact the patient–caregiver relationship.
- It is essential for nurses to experience their own journey regarding the dying process and bring with them a willingness to be transformed by it.

Is it possible to adequately articulate and give definition to meaning in illness? Or is meaning in illness better described and understood through using symbolism and metaphors such as the above poem? To try to define that which is enigmatic and bordering on the ineffable seems almost sacrilegious. The unique individual journey of finding meaning in illness experienced by each patient facing the end of life and their family caregiver would seem to be diminished by the very process that seeks to understand through the use of language.

Is it that we seek to find meaning in illness or is it that we seek to find meaning in the life that is now left and in those relationships and things we value? Do we seek to find meaning in illness itself as an isolated event or that which is beyond the illness, such as how to live out this newly imposed way of life? Terminal illness forces us to look at and possibly to reappraise the meaning in and of our life.1 If we allow space in our lives for the process of meaning in illness to unfold, we then move from the superficial to the profound.

Terminal illness also forces us at some point to look directly at death, yet we resist getting in touch with the feelings that arise. Everything in us seeks life. Everything in us hopes for life. Everything in us denies death. There is something very cold, very unmoving, and very disturbing about it all. Does the end of one's human existence on earth need to be the sole metaphor for death?

Even though end-of-life issues have progressed nearer to the forefront of health care, the dying patient is still the recipient of an impersonal, detached, and cure-focused system, thereby exacerbating an already catastrophic situation. As necessary as it is for nurses to use the nursing process, it is not enough. The patient's illness odyssey beckons us to go beyond assessment, diagnosis, intervention, and evaluation to a place of vulnerability, not in an unprofessional manner but, rather, in a way that allows for a shared connectedness unique to each patient-nurse relationship. We need to be willing to use feelings appropriately as part of the therapeutic process. Separating ourselves from touching and feeling to protect ourselves...
only serves to make us more vulnerable, because we have then placed our emotions in isolation. Nurses can be a catalyst for helping the patient and family find meaning in the illness, and, in the process, help themselves define or redefine their own meaning in life, illness, and death.

Meaning Defined

Johnston-Taylor2 presents several definitions for meaning (Table 32–1). In the dictionary,3 one finds meaning defined simply as “something that is conveyed or signified” or as “an interpreted goal, intent, or end.” But it is the etymology of the word “mean” that helps nursing come to understand our potential for supporting patients in the process of finding meaning in their lives, even as they face death. Mean comes from the Old English *maenan*, “to tell of.” One does not find meaning in a vacuum; it has everything to do with relationships, spiritual-ity, and connectedness. While the process of finding meaning depends greatly on an inward journey, it also relies on the telling of that journey. The telling may use language, but it may also be conveyed by the eyes, through the hands, or just in the way the body is held. Frankl4 reminds us that the “will to meaning” is a basic drive for all of humanity and is unique to each individual. A life-threatening illness begs the question of meaning with a new urgency and necessity.

Cassell5 tells us that “all events are assigned meaning,” which entails judging their significance and value. Meaning cannot be separated from the person’s past; it requires the thought of future and ultimately influences perception of that future (p. 67). Finding meaning is not a stagnant process; it changes as each day unfolds and the occurrences are interpreted. As one patient reflected upon her diagnosis, “Cancer changes your perception of your world and life.”6 Coming face to face with one’s mortality not only defines what is important but also the poignancy of the loss of much that has been meaningful.

One’s spirituality is often the key to transcending those losses and finding ways to maintain those connections, whether it is the belief that one’s love, work, or creativity will remain after the physical separation or the belief that one’s spirit goes on to an afterlife or through reincarnation. Meaning in life concerns the individual’s realm of life on earth. It has to do with one’s humanness, the temporal, and the composites of what one has done in life to give it meaning. Meaning of life has more to do with the existential. It is looking beyond one’s earthly physical existence to an eternal, secure, and indelible God or spiritual plane. The existential realm of life provides a sense of security whereby one can integrate experiences.7

Spirituality has been defined as a search for meaning.8 One of the Hebrew words for meaning is *biynah* (bee-naw), which is understanding, knowledge, meaning, and wisdom. It comes from the root word *biyn* (bene), to separate mentally or to distinguish.9 How is it that one can come to knowledge and understanding? Patients receiving palliative care often describe a sense of isolation and loneliness. They frequently have endless hours available, while at the same time experiencing a shortening of their life. It is here that nursing has a pivotal role as the listener, for when the ruminations of the dying are given voice, there is an opportunity for meaning. Important life themes are shared, and the unanswerable questions are at least
asked. As the stranger develops intimacy and trust, meaning takes hold.

Suffering creates one of the greatest challenges to uncovering meaning. For the dying patient, suffering comes in many packages: physical pain, unrelenting symptoms (nausea, pruritus, dyspnea, etc.), spiritual distress, dependency, multiple losses, and anticipatory grieving. Even the benefits of medical treatments given to provide hope or palliation can sometimes be outweighed by side effects (e.g., sedation and constipation from pain medication), inducing yet further suffering. The dictionary defines suffering in this way: “To feel pain or distress; sustain loss, injury, harm, or punishment.” But once again, it is the root word that moves us to a more primitive understanding, the Latin sufferer, which comprises sub, “below” and ferre “to carry.” The weight and isolation of that suffering now becomes more real at the visceral level. Cassell reminds us that pain itself does not foreordain suffering; it is, in fact, the meaning that is attributed to that pain that determines the suffering. In his clinical definition, “Suffering is a state of severe distress induced by the loss of the intactness of person, or by a threat that the person believes will result in the loss of his or her intactness” (p. 63). Suffering is an individual and private experience and will be greatly influenced by the personality and character of the person; for example, the patient who has needed control during times of wellness will find the out-of-control experience of illness as suffering. In writing about cancer pain and its meaning, Ersek and Ferrell provide a summary of hypotheses and theses from the literature (Table 32–2).

Although not always recognized, it is the duty of all who care for patients to alleviate suffering and not just treat the physical dimensions of the illness. This is no small task, for first, professionals must be free from denial and the need to self-protect to see the suffering of another. Then, they must be able to attend to it without trying to fix it or simplify it. The suffering needs to be witnessed; in the midst of suffering, presence and compassion become the balm and hope for its relief.

The Process of Finding Meaning in Illness

From years of working with terminally ill patients and their families, the authors have found that the process of finding meaning in illness invokes many themes. The title given to each theme is an attempt to represent observed transitions that many terminally ill patients seem to experience. Not all patients experience the transitions in order, and not all transitions are experienced. However, we have observed that these transitions are experienced by the majority of patients. Issues faced by family caregivers and health care professionals are discussed in later sections. The themes shared in this section are the imposed transition, loss and confusion, dark night of the soul, randomness and absence of God, brokenness, and reappraisal. In experiencing some or all of these transitions, one can perhaps find meaning in this difficult time of life.

The Imposed Transition

Being told that you have a terminal illness can be like hearing the sound of prison doors slam shut. Life will never be the same. The sentence has been handed down and there is no reversing the verdict. ‘Terminal illness is a loss, and there is nothing we can do to change the prognosis even though we may be able to temporarily delay the final outcome. The essence of our being is shaken, and our souls are stricken with a panic unlike any other we have ever felt. For the first time, we are faced with an ‘existential awareness of nonbeing.’ For a brief moment, the silence is deafening, as if suspended between two worlds, the known and the unknown. As one ‘regains consciousness,’ so to speak, the pain and pandemonium of thoughts and emotions begin to storm the floodgates of our faith, our coping abilities, and our internal fortitude, while simultaneously the word “terminal” reverberates in our heads. There is no easy or quick transition into the acceptance of a terminal diagnosis.

Facing the end of life provokes questions. Not only is the question “why me?” asked, but questions regarding the meaning in one’s life as well as the meaning of one’s life. Whether we embrace with greater fervor the people and things that collectively give us meaning in life or we view it all as now lost, the loss and pain are real. Nothing can be done to prevent the inevitable. There is a sense of separation or disconnectedness in that while I am the same person, I have also become permanently different from you. Unless you become like me, diagnosed with a terminal illness, we are in this sense, separated. In a rhetorical sense, the meanings we gain in life from relationships and the material world serve to affirm us as participants in these meanings. When these meanings are threatened by a terminal diagnosis, we fear the loss of who we are as functioning productive human beings. The affirmations we received from our meanings in life are now at a standstill.

A 50-year-old contractor, determined to fight for his life despite his terminal prognosis, was not only combating cancer but also trying to hold onto who he was. If word got out that he had cancer, he feared that no one would hire him. He felt that his wife depended on him to bring home a salary, so they kept the news of his illness even from close friends. He exhausted himself trying to keep up with work and the image that he was all right. When this was explored with him, he began to understand that he saw himself in limited functional ways, the contractor and the husband as a provider, and he feared losing what had defined his life. Having him define his life in terms of meaning, expanding his past limited view gave him new insight and gradually allowed him to open up and share his prognosis with close friends.

In addition to questioning meaning in life, those facing the end of life also question the meaning of life. A life-threatening illness makes it difficult to maintain an illusion of immortality. What happens when we die? Is there really a God? Is it too late for reconciliation? For those believing in life after death, the questions may focus on uncertainty of eternal life, fear of what eternal life will be like, or the possibility of this being a test of faith. No matter what the belief system, the existential questions are asked. We reach out for a connection with God or something beyond one’s self to obtain some sense of security and stability. Then, in this ability to transcend the situation, ironically, we somehow feel a sense of groundedness. Frankl states, “It denotes the fact that being human always points, and is directed, to something or someone, other than oneself—be it a meaning to fulfill or another human being to encounter.” There is an incredibly strong spiritual need to find meaning in this new senseless and chaotic world.

Loss and Confusion

One cancer patient stated, “Our lives are like big run-on sentences and when cancer occurs, it’s like a period was placed at the end of the sentence. In reality, we all have a period at the end of the sentence, but we don’t really pay attention to it.” With a terminal diagnosis, life is changed forever, for however long that life may be. Each day life seems to change as one is forced to experience a new aspect of the loss. There is a sense of immortality that pervades our lust for life, and when we are made to look at our mortality, it is staggering. With all of the many losses, coupled with the fear of dying, one can be left feeling confused from the infinite possibilities of the unknown. The panorama of suffering seems to be limitless.

The pain of loss is as great as the pleasure we derived from life. The pain is pure and somewhat holy. The confusion comes not only from one’s world having been turned upside down, but also from those who love us and care about us. It is not intentional; nevertheless, its impact is greatly felt. In trying to bring encouragement or trying to help one find meaning, the loss and pain are sometimes minimized by comparing losses, attempting to save God’s reputation by denying the one hurting the freedom to be angry at God, or, by immediately focusing on the time left to live. The hurting soul needs to feel the depth of the loss by whatever means it can. The pain from loss is relentless, like waves from a dark storm at sea crashing repeatedly against rocks on the shoreline.
A 65-year-old woman with terminal lung cancer experienced further physical decline each day. She was surrounded by a family who lovingly doted on her. She was one who loved life and loved people. Many losses were experienced due to her condition. What added to these losses was the fact that her family wanted her to focus on life and not her disease or death. They knew she was going to die but felt that her quality of life would be better if these issues were not discussed. The patient had many thoughts and feelings to sort through and wanted to talk, but no one was listening. Her loss was not just physical; it was also an imposed emotional loss caused by a loving family trying to do the right thing. The communications with her family were different, constantly reminding her that nothing was the same, and, in turn, reminded her of her losses and impending death.

**Dark Night of the Soul**

The descent of darkness pervades every crack and crevice of one’s being. One now exists in the place of Nowhere surrounded by nothingness that is void of texture and contour. One’s signature is seemingly wiped away, taking with it the identification of a living soul. Job states, “And now my soul is poured out within me; days of affliction have seized me. At night it pierces my bones within me, and my gnawing pains take no rest . . . My days are swifter than a weaver’s shuttle, and come to an end without hope.” One enters the abyss of emptiness—with the perverse twist that one is not empty of the tortured feeling of emptiness. This is pain’s infinite desert.

Darkness looms as one thinks about the past, full of people and things that provided meaning in life, and will soon have to be given up. Darkness looms as one thinks about the future, because death precludes holding on to all that is loved and valued. Darkness consumes one’s mind and heart like fire consumes wood. It makes its way to the center with great fury, where it proceeds to take possession, leaving nothing but a smoldering heap of ashes and no hope of recovering any essence of life.

A woman with young children relapsed after a bone marrow transplant and spent months in the hospital trying an experimental protocol. She suffered greatly, not only from the effects of the chemotherapy, but also from the long separations from her children. When it became clear that her leukemia had once again returned, she became tortured by the thought of abandoning her children at a time when they so greatly needed a mother, and the fact that she had gambled with the little time she had left and had lost. Now too ill to return home, in her mind, her children had the double loss of weeks of quality time she could have had with them and now her imminent death. She became inconsolable because of this darkness. Time to intervene was very limited. Allowing her the room for suffering, and being “present” to this suffering as a nurse, was essential. In addition, helping her to move back into her mothering role and providing for her children by helping to prepare them for her death became the pathway through the darkness and into meaning.

Though one might try, there are no answers theological or otherwise to the “whys” that engulf one’s existence. Death moves from an “existential phenomenon to a personal reality.” All our presuppositions about life fall away and we are left emotionally naked. There is neither the physical, the emotional, nor the spiritual strength to help our own fragility. The world becomes too big for us and our inner worlds are overwhelming. The enigma of facing death strips order from one’s life, creating fragmentation and leaving one with the awareness that life is no longer tenable.

**Randomness and the Absence of God**

The pronouncement of a terminal diagnosis provokes inner turmoil and ruminating thoughts from dawn to dusk. Even in one’s chaotic life, there was order. But order does not always prevail. A young athlete being recruited for a professional sport is suddenly killed in a tragic car accident. A mother of three small children is diagnosed with a chronic debilitating disease that will end in death. An earthquake levels a brand new home that a husband and wife had spent years saving for. A playful young toddler drowns in a pool. There seems to be no reason. It would be different if negligence were involved. For example, if the young athlete were speeding, or driving drunk, although still quite devastating, a “logical” reason could be assigned to the loss. But randomness leaves us with no “logical” explanation.

The word “random” comes from the Middle English word *radon*, which is derived from the Old French word *randon*, meaning violence and speed. The word connotes an impetuous and haphazard movement, lacking careful choice, aim, or purpose. The feeling of vulnerability is overwhelming. In an effort to find shelter from this randomness, meaning and comfort is sought from God or from something beyond one’s self, but how do we know that God or something beyond ourselves is not the cause of our loss? Our trust is shaken. Can we reconcile God’s sovereignty with our loss? Can we stay connected to and continue to pull or gain strength and security from something beyond ourselves that may be the originator of our pain? There is a sense of abandonment by that which has been our stronghold in life. Yet to cut ourselves off from that stronghold out of anger would leave us in a state of total disconnection. A sense of connection is a vital emotion necessary for existence, no matter how short that existence may be. But facing death forbids us to keep our existential questions and desires at a distance. Rather, it seems to propel us into a deeper search for meaning as the questions continue to echo in our minds.

**Brokenness**

Does one come to a place of acceptance within brokenness? Is acceptance even attainable? Sometimes. Sometimes not. Coming to a place of acceptance is an individual experience for each person. Kearney, in a wonderful analogy of acceptance, states, “Acceptance is not something an individual can choose at will. It is not like some light switch that can at will be flicked on or off. Deep emotional acceptance is like the settling of
a cloud of silt in a troubled pool. With time the silt rests on the bottom and the water is clear” (p. 98). Brokenness does, however, open the door to relinquishing the illusion of immortality. Brokenness allows the soul to cry and to shed tears of anguish. It elicits the existential question “why?” once again, only this time not to gain answers but to find meaning.

A woman in her mid-60s, dying of lung cancer, shared how she came to a place of acceptance. When she was first diagnosed, the cancer was already well advanced. Her health rapidly declined, and she was more or less confined to bed or sitting. Out of her frustration, anger at God, sadness, and tears, came the desire to paint again. It was her way of coping, but it became more than that. It brought her to a place of peace in her heart. She had gotten away from painting due to busyness and was now learning to be blessed by quietness. She was very good at replicating Thomas Kinkade paintings, and her final picture, which was to be a gift, included many beautiful flowers. She was always surrounded by flowers.

If we go back to the poem at the beginning of this chapter, it wasn’t until “sanity” was lost that the rose was found. A gradual perception takes place whereby we realize that the way out is by no longer struggling.21 When we come to the end of ourselves and the need to fight the inevitable that is death, we give space for meaning to unfold. It isn’t that we give up the desire, but we relinquish the need to emotionally the situation around and to have all our questions answered. Sittser,16 a minister who experienced a sudden loss of several immediate family members, states, “My experience taught me that loss reduces people to a state of almost total brokenness and vulnerability. I did not simply feel raw pain; I was raw pain” (p. 164). Pain and loss are still profound, but in the midst of these heavy emotions there begins to be a glimmer of light. Like the flame of a candle, the light may wax and wane. It is enough to begin to silhouette those people and things that still can provide meaning.

Reappraisal

It is here where one begins to realize that something positive can come from even a terminal diagnosis and the losses it imposes. The good that is gained does not mitigate the pain of loss, but, rather, focuses on the future, however long that may be. Despair undermines hope, but hope robs death of despair.21

A male patient in his late 30s, facing the end of life after battling leukemia and having gone through a bone marrow transplant, shared that he knew he was going to die. It took him a long time to be able to admit it to himself. The patient recalled recently visiting a young man who had basically given up and did not want his last dose of chemotherapy. He talked a while with this young man and encouraged him to “go for it.” He told him that there’s nothing like watching the last drop of chemo go down the tube and into his body, and the sense of it finally being all over. The patient shared with the young man that when he received his own last dose of chemotherapy, he stayed up until 3 in the morning to watch the last drop go down the tube. While the chemotherapy did not help him to the extent that he wanted, he wanted to encourage the young man to hope and not give up. Life was not yet over. He had tears in his eyes when he finished the story.

Facing end of life with a terminal diagnosis will never be a happy event. It will always be tragic because it causes pain and loss to everyone involved. But at a time unique to each person facing death, a choice can be made as to whether one wants to become bitter and devalue the remaining time, or value as much as possible the time that is left.

An important choice to be made during this time is whether to forgive or to be unforgiving—toward oneself, others, God, or one’s stronghold of security in life. Being unforgiving breeds bitterness and superficiality. As we face the end of life, we need both an existential connection and a connection with others. Being unforgiving separates us from those connections, and it is only through forgiveness that the breech is healed. Forgiveness neither condones another’s actions nor does it mean that this terminal diagnosis is fair. Rather, forgiveness is letting go of expectations that one somehow will be vindicated for the pain and loss. Whether by overt anger or by emotional withdrawal, in seeking to avoid being vulnerable to further pain and loss, we only succeed in making ourselves more vulnerable. Now we have chosen a deeper separation that goes beyond facing the death of the physical body—that of the soul.18 Positive vulnerability through forgiveness provides a means of healing, and, when possible, reconciliation with others. It always provides healing and reconciliation with one’s God or one’s stronghold of security. Forgiveness allows both physical and emotional energy to be used for creating and enjoying the time left for living.

A 30-year-old woman was admitted to the hospital with advanced metastatic breast cancer. She was unknown to the hospital staff but had a good relationship with her oncologist. During the admissions assessment, the young woman could not give the name of anyone to contact in the event of an emergency. When pressed, she stated that she was alienated from her family and chose not to be in touch. She agreed that after her death her mother could be called, but not before. A social worker was summoned in the hope that something could be done to help with some unification. However, the social worker came out of the room devastated by the woman’s resolve. The chaplain also found no way to reconnect this woman’s family. The nursing staff experienced moral distress as they watched this woman die, all alone in the world. One of the authors worked with the staff to help them realize that they had become trusted and in a sense were her substitute family. One may not always be able to fix the pain of life’s fractures or bring people to a place of forgiveness, but it is important not to underestimate what is happening in the moment. Healing for this patient came through the relationship with her doctors and nurses, and she died not alone, but cared for.
There are many emotions and issues with which those facing death must contend. It is not an easy journey and the process is wearing; nevertheless, the rose can be found.

Impact of the Terminal Illness on the Patient–Caregiver Relationship

Each of us comes to new situations with our life’s experiences and the meanings we have gained from them. It is no different when being confronted with illness and the end of life. However, in this special episode of life, there are often no personal “reruns” from which to glean insight. Patient and family come together as novices, each helping the other through this unknown passage. Because different roles and relationships exist, the impending loss will create different meanings for each person involved.

Facing the loss of someone you love is extremely difficult. For the family caregiver, the process of finding meaning can either be facilitated or hindered by the meaning held by the one facing death. One example experienced by one of the authors of this chapter involved a wife’s short discussion with her terminally ill husband on the subject of heaven. She asked him if he thought he was going to heaven and if he was, would she be able to be with him even though she was from a different religion. He assured her that they would someday be together in heaven, and an immediate sense of peace came over his wife. He was not looking forward to dying, but for him, his death was not the end. He would see her again. His own meaning of death helped create a whole new meaning for his wife. He imparted to her a sense of eternal connection that allayed her fears of eternal separation from the most important person in her life. She could now face his death, with sorrow, but without fear.

In another example, a woman helped her family create meaning for themselves from the picture she had painted of herself sitting on the beach as a little girl next to a little boy. She explained that the little boy had his arm around her as they stared out at the sea. Each time the waves covered the surface of the beach and then retreated, the sea would carry with it bits and pieces of her fears and disease. The birds circling overhead would then swoop down to pick up and carry off any pieces not taken by the sea. The little boy’s arm around her signified all the loving support she had received from others. When the time would come for her to die, she would be ready because she had been able to let go of life as she knew it. She had let the waves slowly carry that which was of life out to sea and yet had learned to hold on to the meaning that that life had represented. In doing so, she enabled her family to hold on to the meaning of their relationship with her and to realize that they would never be separated from that meaning.

A final poignant story offers a different perspective. A 53-year-old woman with stage IV ovarian cancer was very angry at everyone and everything and could not seem to find any positive meaning. She was angry that her life would be cut short, and she would not live to see her grandchildren grow. She and her husband had made plans to travel and now she was too ill to make even one of the trips. She made life difficult for those who loved her. She made loving her and caring for her difficult. No one could seem to do anything right. She was bothered by company yet wanted someone with her all the time, and she did not like the intrusion of health care professionals in her home. She felt that her physician and family had given up on her and she resented it. She died a very angry and unhappy woman. This was extremely difficult for her family. The family was left feeling rather fragmented. What exactly did all of this mean? They had spent so much time trying to please the patient, which was almost impossible, that they never had time to synthesize the events and their feelings regarding the whole terminal illness trajectory. Not only did the family have their own pain from loss, they were left with final memories that created negative meanings. For example, various family members had begun to withdraw emotionally from the patient out of hurt and frustration, yet felt guilty for “abandoning” her. After her death, those family members still felt guilty because they had really wanted to be with her.

These actual patient stories were given to exemplify how the patient’s meaning in illness affects the meaning held or created by family members. Differing or divergent meanings can be detrimental in a relationship, or they can be used to strengthen it, thereby increasing the quality of time left together. That is not to imply that the patient is responsible for the meaning created by family members, but how one affects the other. Germino, Fife, and Funk suggest that the goal is not merely converging meanings within the patient-family dyad, but rather, encouraging a sharing of individual meanings so that all can learn, and relationships can be deepened and strengthened.

There are many issues that family caregivers face in caring for a loved one nearing the end of life. They are discussed at length in the literature. There is one issue, however, that warrants more attention—the loss of dreams. The loss of dreams for a future with the person is in addition to the loss of the person. It is the loss of the way one used to imagine life, and how it would have been with that person. It is the loss of an emotional image of oneself and the abandonment of chosen plans for the future and what might have been.

For a child and the surviving parent, those losses of dreams will be played out each time Mother or Father’s Day arrives and important life-cycle events, such as graduations, weddings, or the birth of the first grandchild. As her mother lay dying, one child expressed that loss in the simple statement, “Mommy, you won’t be here for my birthday!” The mother and child wept, holding and comforting each other. Nothing could change the loss, but the comforting would remain forever.

The loss of dreams is an internal process, spiritual for some, seldom recognized by others as needing processing. Nurses have a wonderful opportunity at this point to verbally recognize the family caregivers’ loss of dreams and to encourage them in their search to find meaning in the loss. The ability to transcend and connect to God or something greater than one’s self helps the healing process.
Transcendence: Strength for the Journey That Lies Ahead

Transcendence is defined as lying beyond the ordinary range of perception; being above and independent of the material universe. The Latin root is trans-, “from or beyond,” plus scandere, “to climb.” The images are many: the man in a pit climbing his way out one handhold at a time; the story of Job as he endured one defeat after another and yet found meaning; the climber who reaches the mountaintop, becoming closer to the heavens while still having the connection to the earth; or the dying patient who, in peace, is already seeing into another reality. The ability to transcend truly is a gift of the human spirit and often comes after a long struggle and out of suffering. It is often unclear which comes first—does meaning open the door for transcendence or, quite the opposite, does the act of transcendence bring the meaning? More than likely, it is an intimate dance between the two, one fueling the other. In the Buddhist tradition, suffering and being are a totality, and integrating suffering in this light becomes an act of transcendence.

Transcendence of suffering can also be accomplished by viewing it as preparation for sins while still living, preparing the way for eternity, as in the Islamic tradition. In other traditions, transcendence is often relationship based, the connection to others, and sometimes to a higher power. For example, the Christian seeing Christ on the cross connects one to the relationship and endurance of God and the reality that suffering is a part of life. For others, it is finding meaning in relating to others, even the act of caring for others. And for some, that relationship may be with the earth, a sense of stewardship and leaving the environment a better place. It is rare that patients reach a state of transcendence and remain there through their dying. Instead, for most it is a process in which there are moments when they reach a sense of expansion that supports them in facing death. The existential crisis does not rule, because one can frame the relationship beyond death; for example, “I will remain in their hearts and memories forever, I will live on through my children, or my spirit will live beyond my limited physical state.”

Nursing Interventions

If one returns to the root word of meaning, maenain, “to tell of,” this concept can be the guide that directs the nurse toward interventions. Given the nature of this work, interventions may not be the true representation of what is needed. For intervention implies action that the nurse has an answer and she can direct the course of care by intervening. It is defined as “To come, appear, or lie between two things. To come in or between so as to hinder or alter an action.” But finding meaning is process oriented; while finely honed psychosocial skills and knowledge can be immensely helpful, there is no bag of tricks. One example would be of a chaplain who walks in the room and relies only on offering prayer to the patient, preventing any real discourse or relationship building. The patient’s personhood has been diminished and, potentially, more harm than good has been done.

So let us revisit “to tell of.” What is required of the professional who enters into the healing dimension of a patient’s suffering and search for meaning? It would seem that respect may be the starting point, respect for that individual’s way of experiencing suffering and attempts of making sense of the illness. Secondly, allow for an environment and time for the telling. Even as this is written, the sighs of frustration are heard, “We have no time!” If nursing fails at this, if nurses turn their backs on their intrinsic promise to alleviate suffering, then nursing can no longer exist. Instead, the nurse becomes simply the technician and the scheduler—the nurse becomes a part of the problem. She has violated the Code for Nurses that states, “Nursing care is directed toward the prevention and relief of the suffering commonly associated with the dying process . . . and emphasizes human contact.”

If patients in the midst of suffering receive the message, nonverbal or directly, that there is no time, energy, or compassion, they will, in their vulnerability, withdraw or become more needy. Their alienation becomes complete. On the other hand, if privacy and a moment of honor and focused attention are provided, this allows for the tears to spill or the anguish to be spoken. Then the alienation is broken, and the opportunity for healing one dimension is begun. The terminally ill are a vulnerable population. They die and do not complete patient satisfaction surveys; their grievances, and their stories die with them. But the violation does not, for each nurse now holds that violation, as does society as a whole. The wound begets wounds, and the nurse sinks further into the protected and unavailable approach, alienated herself. The work holds no rewards, only endless days and demands. She has nothing left to give. The patient and family are ultimately abandoned. In the work of Kahn and Steeves, one finds a model for the nurse’s role in psychosocial processes and suffering. It represents the dynamic relationship of caring, acted out in caregiving as well as in the patient’s coping, which transform each other.

For the nurse to provide this level of caregiving, she must understand the obstructions that may interfere. It is essential that the nurse undergo her own journey, visiting the intense emotions around the dying process and the act of witnessing suffering. We can serve the suffering person best if we ourselves are willing to be transformed through the process of our own grief as well as by the grief of others. Presence may, in fact, be our greatest gift to these patients and their families. Still, imagine charting or accounting for presence on an acuity system! Presence “transcends role obligations and acknowledges the vulnerable humanness of us all . . . to be present means to unconceal, to be aware of tone of voice, eye contact, affect, and body language, to be in tune with the patient’s messages.” Presence provides confirmation, nurturing, and compassion and is an essential transcendent act.

Touch becomes one of the tools of presence. Used with sensitivity, it can be as simple as the holding of the hand, or as
powerful as the holding of the whole person. Sometimes, because of agitation or pain, direct touch becomes intrusive; even then touch can be invoked, by the touching of a pillow, the sheet, or the offering of a cold cloth. Healing touch takes on another level of intention through the directing energy of prayer.

If a key aspect of meaning is to tell, then one might be led to believe that the spoken word would be imperative. Yet over and over, it is silence that conveys the meaning of suffering, “a primitive form of existence that is without an effective voice and imprisoned in silence.” Compassionate listeners in respect and presence become mute themselves. They use the most intuitive of skills to carry the message. This may also be why other approaches that use symbols, metaphors, and the arts are the most potent in helping the patient to communicate and make sense of meaning. The arts, whether writing, music, or visual arts, often help the patient not only gain new insight, but convey that meaning to others. There are many levels on which this is accomplished. Whether it is done passively, through reading poetry, listening to music, or viewing paintings, or actively through creation, thoughts can be inspired, feelings moved, and the sense of connectedness and being understood can evolve. What once was ubiquitous can now be seen outside of one’s soul, as feelings become tangible. It can be relational, because the act of creation can link one to the creator, or it can downplay the role of dependency, as the ill one now cares for others with a legacy of creational gifts.

Meditation is another act of transcendence that can be extremely powerful for the dying. Even those who have never experienced a meditational state can find that this new world in many ways links them to living and dying. The relaxation response that allows the anxious patient to escape into a meditative state, experiencing an element of control while relinquishing control. Many patients describe it as a floating state, a time of great peace and calm. Some, who have never had such an experience, can find the first time frightening, as the existential crisis, quelled so well by boundaries, is no longer confined. Most, given a trusting and safe teacher, will find that meditation will serve them well. The meditation can be in the form of prayer, guided imagery, breathing techniques, or mantras.

Prayer is well documented in the literature as having meaning for patients and families; not only does it connect one to God, but it also again becomes a relational connection to others. Knowing that one is prayed for not only by those close at hand, but by strangers, communities, and those at a great distance can be deeply nurturing. Often forgotten is the role the patient can be empowered in, that of praying for others. One of the authors experienced her patient’s prayers for her as the tables were turned, and the patient became the healer. The patient suddenly lost the sense of worthless and glowed with joy.

Leaving a legacy may be one of the most concrete ways for patients to find meaning in this last stage of their lives. It most often requires the mastering of the existential challenges, in which patients know that death is at hand and choose to direct their course and what they leave behind. For some patients, that will mean going out as warriors, fighting till the end; for others, it will mean end-of-life planning that focuses on quality of life. Some patients will design their funerals, using rituals and readings that reveal their values and messages for others. Others will create videos, write letters, or distribute their wealth in meaningful ways. Parents who are leaving young children sometimes have the greatest difficulty with this aspect. On one hand, the feelings of horror at “abandoning” their children are so strong that they have great difficulty facing their death. Still, there is often a part of them that has this need to leave a legacy. The tug-of-war between these two willful emotions tends to leave only short windows of opportunity to prepare. The extreme can be the young father who began to push his toddler away, using excuses for the distancing. It was only after a trusting relationship had been established with one of the authors that she could help him to see how this protective maneuver was, in fact, harming the child. The father needed not only to see what he was doing, but to see how his love would help the child and how others would be there for the child and wife in their pain and grief. With relief, the father reconnected to his young son, creating living memories and a lifetime protection of love.

Another courageous parent anticipating the missed birthdays, bought cards and wrote a note in each one, so that the child would be touched not only by the individual messages, but the knowledge that the parent found a way to be there for him with each new year. A mother wrote a note for her young daughter, so that if she should ever marry, she would have a gift to be opened on her wedding day. The note described the mother’s love, wisdom about marriage, and her daughter’s specialness, already known through a mother’s eyes. An elderly person may write or tape an autobiography or even record the family tree lest it be lost with the passing of a generation. The nurse can often be the one who inspires these acts, but always it must be done with great care so as not to instill a sense of “should” or “must,” which would add yet another burden.

Helping patients to reframe hope is another important intervention. Recently, Dr. William Brietbart, Chief of the Psychiatry Services at Memorial Sloan-Kettering Cancer Center in New York City, designed and conducted research on a meaning-centered psychotherapeutic intervention to help terminally ill patients with cancer maintain hope and meaning as they face the end of their lives. This research was inspired by the works of Dr. Victor Frankl, a psychiatrist and Holocaust survivor. Cancer patients attended an 8-week, group-focused, standardized course of experiential exercises that addressed constructs of despair at the end of life such as hopelessness, depression, loss of meaning, suicidal ideation, and desire for a hastened death. What was discovered during the study was that the patient’s spiritual well-being, loss of meaning in part, was more highly correlated to the components that made up despair at the end of life than either depression or hopelessness alone. As a result, if the patient could manipulate or reframe his/her sense of meaning and spiritual well-being, this would positively affect the foundational elements of despair at the end of
The Health Care Professional

While the health care professional can be educated about death and grieving, like the patient and family, it is in living out the experience that understanding is reached. It is a developmental process and, given the demands of the work, the nurse is at great risk for turning away from her feelings. There is often little mentoring that accompanies the first deaths, let alone formal debriefing or counseling. How can it be that we leave such important learning to chance? And what about cumulative losses and the years of witnessing suffering? Health care needs healing rituals for all of its health care professionals to support and guide them in this work. Individual institutions can develop programs that address these needs.

At one institution, “Teas for the Soul,” sponsored by the Pastoral Care Department, provide respite in the workplace on a regular basis, as well as after difficult deaths or traumas. A cart with cookies and tea, plus soft music, are provided as physical nurturance, as well as nurturing the emotions of the staff and legitimizing the need to come together in support. Another support is a renewal program, the “Circle of Caring.” This retreat supports health care professionals from a variety of institutions in a weekend of self care, integrating spirituality, the arts, and community building. The element of suffering is a focal point for a small group process that unburdens cumulative effects of the work and teaches skills and rituals for coping with the ongoing demands.

Clearly, there is much that can be done in this area to support nurses individually and to support organizations. There are many opportunities for assisting nurses in their own search for meaning and enhancing the care of patients and families. When the nurse takes the time to find meaning in this work, he or she is finding a health restorative practice that will protect her personally and professionally. Like the patient, he or she will need to choose this journey and find pathways that foster and challenge her.

As long as we can love each other,
And remember the feeling of love we had,
We can die without ever really going away.
All the love you created is still there.
All the memories are still there.
You live on – in the hearts of everyone you have
Touched and nurtured while you were here.
—Morrie Schwartz

I first met Ruth and Jerry in the summer of 1987. Jerry had advanced prostate cancer, and both he and Ruth were working hard to maintain a quality of life that gave continued meaning and purpose to their existence. After Jerry’s death, Ruth continued to be part of our Pain and Palliative Care Service, always vocal with suggestions and always eager to come up with ways to help patients and families live to their fullest potential in the face of advancing disease as she and Jerry had strived to do. Communication was a constant theme—communication between patients and their doctors.

Out of this urge to improve communication, four films were born. The first was an outgrowth of Ruth’s experience with the staff. She wondered what happened when a member of the staff or a member of their family got cancer—what happened to them as a person. The documentary When Doctors Get Cancer was an outgrowth of that question and Ruth’s first venture into the world of filmmaker as a producer and director. Her second film, Cancer: A Personal Voyage, grew out of the first film. Ruth had become friends with Peter Morgan, the youngest physician who participated in her film. After Peter’s death, his family, having seen Ruth’s first film, shared with her his diary, which detailed his journey with cancer. Cancer: A Personal Voyage, tells of his moving and courageous journey. Her third documentary, Less Pain More Love, depicts the struggle of children with cancer.

In the meantime, Ruth’s life was bound up in the life and work of Viktor Frankl. She found that no philosophy worked better for her than that of Frankl. She wanted people to recognize that the “greatest thing we have is the other,” and she works to enable people to improve their lives through developing a meaningful mindset. Her fourth documentary, Frankl’s Choice, also known as The Choice is Yours, was born out of wanting to share with others what she had learned from Frankl. Ruth reflects on her own journey in the following piece.—Nessa Coyle

It is 18 years since that fatal Monday morning when Jerry went into his final sleep. As I sat on his bed in the hospital with a nurse, sharing that unbelievable moment in our lives, she quietly kept on encouraging me—“Let him fly away and be free.” I would touch his body that contained all the warmth of life and felt my unreality.

How could this be all over, I asked myself. Jerry never gave up. We had a “game” through all this. He would ask “If I make it to 85, is that good enough?” I always responded in the negative. “If the number is in the 90s?” I always said it was still not good enough. Our marriage of 28 years was like 28 days. As I recall it 18 years later, it was a shared journey.

Fortunately, the nurse was there to accompany me in those painful moments. When the funeral director asked me whether any family members wanted to say their goodbyes, I remained alone and asked the nurse to go with me. I had the first reality shock when I kissed Jerry’s face and experienced his cold, stone-like body shouting in my ear, “I am no longer of your world.” The burial was a blur of in-and-out detachment. I only recall covering Jerry with nature’s blanket and asking him to wait for me to meet him again.

The months following Jerry’s death were complicated. I felt a sense of abandonment. Yet, at the same time, I realized that I had the devotion of a few precious professionals who had been Jerry’s caregivers both in New York and California. Even though we lived in New York City, Jerry chose to receive part of his care at a hospital in California because of their expertise in treating prostate cancer with radiation when surgery was not an option. He traveled to California every 4 months for 9 years.

The constancy of caring that I received from my friends at the cancer center was sacred to me. They understood my grief in countless loving ways. One particular time stands out in my memory. One Saturday morning, our Sabbath and our most holy day, Yom Kippur, I was sitting at my husband’s bedside reading my prayer book when the door opened slightly. A hand motioned for me to come out into the hall. Here stood the neurologist who was treating Jerry for his severe pain. She
stated that she had come to be with me on this day. We spent the day together in silence until sundown. I was overwhelmed.

The nurse, two of our physicians, and the hospital rabbi became “family” in ways that strengthened me and prepared me to live in my “new world.” Grieving for each person is unpredictable. Jerry died on December 7, 1987. Our resident at the California Medical Center had grown very attached to us. We loved him. He phoned me regularly after Jerry’s death, always checking on me. One dismal Friday February afternoon, the resident phoned to say that his chief had arranged for him to have a radiation rotation in New York. He was coming to stay with me. This was a miracle. I realized he wanted to help me in my grief. In spite of the disparity in age, we did things together. We exercised together, took walks together, cooked together, and most of all, laughed together. It was truly heaven until he had to return to California. On reflection, though many years ago, I still feel the capacity of this young man to empathize with the loneliness of another human being in those difficult days. He saw the need to rescue me. The capacity to find a new routine requires a good friend when family is unavailable.

As I ruminated on the future, I decided to go to Fordham University, which was a 10-minute walk from my apartment. During Jerry’s illness, he had gone to Fordham and had thrived in that setting. In fact, I am certain that he tolerated his illness in remarkable ways because he had an environment that enabled him to realize the joy of learning was there for him. In 1989, I enrolled as a student at Fordham University—Jerry had been gone for 2 years. My 2½ years there stimulated me beyond belief. Life began to resonate again. Rediscovering the gift of learning energized my soul. It was then I became conscious of how I wanted to use whatever time would be allotted me on this earth. It was blatantly clear that my life with Jerry would enable me to give to others as we had totally given to each other. I started dreaming of how I might use my time to influence others who needed to discover ways of developing a meaningful mind-set. My passion to “reach for the moon” might seem bizarre, but I decided to go for it.

One afternoon I visited the New York neurologist who had cared for Jerry over the years, feeling comfortable to share my wild ideas with her. I explained how lucky Jerry had been to have me as his advocate. I told her that I had observed time and again that most patients and families seemed unable to have an honest exchange with their physicians because neither party seemed to understand the value of true dialogue. To overcome this situation, I told her that I wanted to make a documentary involving physicians who had cancer. Her response was that Hollywood had made one recently; further, did I have the funds for this idea? When it was clear that I was a novice in filmmaking, the neurologist said to come back when I had the money. It took me 2 years to find the funds, but, with them, I found my life. I was now 75 years old.

In the 10 years that have followed, my life has been an adventure. I have produced four documentaries, each of which has enabled me to uncover a part of myself, continuously unlocking the mystery of living. I am convinced that my psychic suffering has been my “learning field.” Experiencing the pain of Jerry’s death, yet having the staying power to remain constant to my feelings in some indescribable way, opened up a creative universe for me. Producing my films enabled me to express my longings and my vision for those I may never meet but treasure in my being.

During Jerry’s bout with cancer, he uncovered the wisdom of Viktor Frankl in Man’s Search for Meaning. Frankl became my “companion” after Jerry was gone. His philosophy guided me through my darkest moments, teaching me that each of us has the capacity to transcend pain and disappointment. My creative journey has brought me into the lives of such remarkable people, and even though several of them are no longer here, they remain “alive” in different ways. I believe their contributions seen on film will continue to benefit those who view them. Each documentary has its own particular message. My film devoted to Frankl incorporates his concepts. I apply them to my daily life, inspiring me to give the best of myself to whatever task I undertake.

Living in the moment, every moment, has offered me rewards that are sometimes overwhelming. My responsibility is to be the best I can be in my daily tasks, from which I must not run. I find it helps me to acknowledge life’s hurts, bruises, and disappointments, yet enables me to move on to a better space. Bringing something of beauty into each day is a continuing aspect of my agenda. Regardless of life’s pressures, the ability to “feed” myself is essential. I awaken daily to Frankl’s exercise of quickly naming the 10 best things in my life. I have found that they are always changing, which opens my mind to look, see, and be part of this glorious world. I reach for a favorite CD (Gustav Mahler), a poem, my memory bank, or some experience that I treasure. I have tested this system recently under a time of great personal stress and pain and can confirm its effectiveness. I believe caregivers in our society face constant challenges that surely require them to nurture themselves. It is only then that they can have the capacity to enter into and fully participate in the struggle of another.

The philosophy of Martin Buber explains the significance of the moment when we are called on to dialogue with another. It takes discipline and constant emotional energy to be able to feel the “Thou” of the other under powerful conditions. We all need to be understood and to be treated with respect—I did and do. Buber demonstrates the hurtfulness when one is perceived psychologically as an “It.” A part of the divine is within each of us and requires us to honor the other.

In retrospect, witnessing Jerry’s suffering was my real challenge. Over the 10 years he had cancer, we worked at our respective professions, always striving to live in a better space. One of my greatest pleasures was to read to him. In those last months at the Cancer Center in New York, Jerry and I meditated twice daily. We visualized the cancer cells being washed away. Many times it was like magic. He would announce “I feel terrific! Let’s walk on the Champs Elysées” (the corridor around the nursing station). The corridors were filled with prints of great painters, many of which were impressionists. He would walk with his aluminum canes, viewing the pictures as we had done in the
museums. There was a Monet, *The Beach At St. Adresse,* which was his favorite. One night he awakened at 2 A.M as I slept on a cot in his room, asking me to take the print from our room and exchange it for the Monet. As you can imagine, I quickly slipped into my robe, took our “masterpiece” under my arm, secretly and softly removing the Monet and hanging the other in its place. Suddenly, the night nurse appeared. “What are you doing at this hour of the night, Ruth?” she questioned. I pleadingly explained that Jerry loved the Monet as she insisted that I had no right to move the picture from that wall. Since I already had it in hand, I told her Jerry had such a limited time to enjoy it and, therefore, it should be on “loan” for the duration of his stay. I marched back with it, and at that hour he was able to express his delight.

One memorable dialogue with me took place after the surgeon informed him that he was “coming down to the wire,” and it appeared that there was nothing of benefit that could be offered. Jerry asked that I close the door. Alone with him, he insisted that I take an oath (this he had discovered to be a comforting and reassuring way to share his deepest concerns). Before his last hospital admission, Jerry determined he wanted to go to my analyst. The doctor gave him an appointment right after mine. I took him in his wheelchair, and he waited in the waiting room during my session, as I did during his session. Jerry elucidated his wishes that had probably been in his mind for many weeks. He had the analyst take an oath that he would never abandon me—that would enable him to die in peace. The oath asked of me was powerful—Jerry said, “I have had my care at two hospitals. I have thought of mistakes in both of them. But, as a lawyer, I can tell you, we all make mistakes, though most of us won’t admit it. I have made plenty of mistakes in my life. So, I want you to swear that when I am gone, you will never fault them. They did the best they could and I love them.” I agreed as we both reflected on that memorable day. Then I lit the incense and we held hands.

My struggle was bound up in separation. I wanted to have Jerry “inside of me” when we were not together and this I accomplished. I was able to recall him at any moment—during a meeting or alone on a bus, he could be present in my psyche. By giving Jerry my best, I never betrayed myself. As an octogenarian, life glistens for me in countless ways. Blessings abound: good health . . . my son . . . family, though far away . . . my work . . . and a few precious friends. With each day, I hope I can return the infinite goodness life has given me. We are all precious members of this universe and are here to make it a bit better through our resolve as honest, sincere partners in every moment.
V
Special Patient Populations
This chapter defines culture and its components as they relates to palliative care. It addresses cultural competence and the importance of recognizing how one’s own values, practices, and beliefs impact care. Finally, selected palliative care issues influenced by culture are discussed. This chapter is not intended to be a “cookbook” approach to describing behaviors and practices of different cultures as they relate to palliative care, but, rather, a guide to raising awareness of the significance of cultural considerations in palliative care.

Culture and Palliative Care Nursing

The essence of palliative nursing is to provide holistic supportive care for the patient and the family living with a life-limiting illness. Palliative nursing strives to meet the physical, emotional, social, and spiritual needs of the patient and family across the disease trajectory. In an effort to meet these needs, nurses must recognize the vital role that culture has on one’s experience of living and dying. The beliefs, norms, and practices of an individual’s cultural heritage guide one’s behavioral responses, decision-making, and actions. Culture shapes how an individual makes meaning out of illness, suffering, and death. Nurses, along with other members of the interdisciplinary team, partner with the patient and family to ensure that patient and family values, beliefs, and practices guide the plan of care.

The following case illustrates the distress experienced by the patient, family, and health care team when cultural implications of care are not considered.

Case Study
Mrs. Wu, a Patient with Lung Cancer

Mrs. Wu, a 78-year-old Chinese American woman, was diagnosed 7 months ago with non-small cell lung cancer.
She is admitted to the oncology unit of the hospital with severe dyspnea and weakness. Her husband died several years ago, and she has been living with her eldest unmarried son, who has taken a leave of absence from work to care for her. When asked how she is feeling, she states she is “fine” and reports no symptoms. The nurses note that she appears to be in severe pain, wincing with a furrowed brow and moaning with any movement. The son does not want his mother “sedated with pain medication” and tells the nurses “No one is to tell my mother that she has cancer. We have not told her and do not want her to know because she would give up hope.” Mrs. Wu’s only other child, a married son who lives 500 miles away, has come to visit and speaks privately with the nurse. He tells the nurse that he understands his mother is very ill and dying, but he must respect his brother’s decisions about his mother’s care. The nursing staff believes Mrs. Wu is suffering needlessly and should be fully informed of her diagnosis and prognosis. The nurses have struggled with the son’s beliefs, trying to convince him to allow his mother to be medicated for pain. The nurses are upset at the son’s request not to tell his mother her diagnosis. In addition, they are concerned that Mrs. Wu appears very depressed, never making eye contact with them and rarely talking.

On the second evening of the hospital stay, the nurse caring for Mrs. Wu asks the covering physician to consider ordering an antidepressant. While assessing Mrs. Wu, the physician tells her that she is dying from lung cancer. The family returns in the morning to find their mother quite distraught, and they are so angry that Mrs. Wu appears very depressed, never making eye contact with them and rarely talking.

**Increasing Diversity in the United States Population**

As the United States becomes increasingly diverse, the range of treasured beliefs, shared teachings, norms, customs, and languages challenge the nurse to understand and respond to a wide variety of perspectives. In 2000, the population in the United States exceeded 280 million people. Population statistics illustrate that cultural diversity is increasing among the five most common pan-ethnic groups, which are federally defined as American Indian/Alaskan native, Asian/Pacific Islander, black, Hispanic, and white (Table 34–1). By 2030, the population of Hispanic and Asian/Pacific Islander will nearly double that of 1998. Immigrants and their children will account for nearly one half of the growth of the U.S. population. Trends suggest that by 2050, one out of every two Americans will claim membership from what is currently an ethnic minority.

**Culture Defined**

Culture is the “learned, shared and transmitted values, beliefs, norms and life ways of a particular group that guide their thinking, decision, actions in patterned ways—a patterned behavioral response.” Culture is shaped over time and is constantly changing. It is a dynamic system in which the beliefs, values, and lifestyle patterns pass from one generation to another. While culture is often thought of as race and ethnicity, the definition of culture expands far beyond, encompassing such dimensions as gender, age, differing abilities, sexual orientation, religion, financial status, residency, employment, and educational level. Each dimension plays a role in shaping patient and family responses to life-threatening illness.

A broad definition of culture recognizes various subcultures an individual may associate with that shape experiences.
and responses in any given situation. The nurse must also be constantly aware that the culture of the health care system and the culture of the nursing profession shape how he or she responds to interactions with patients, families, and colleagues.

Components of Culture

Race

The commonly held misconception that “race” refers to biological and genetic differences and “ethnicity” refers to cultural variation is outmoded.9 Race does not exist as a natural category, but as a social construct.5,9 Any discussion of race must include the harsh reality of racism issues and disparities that have plagued society and continue to exist even today. Recent studies have demonstrated the discrimination of persons of certain races regarding health care practices and treatment options.6 When viewed in relation to specific races, morbidity and mortality statistics point to serious gaps in access to quality care. Racial disparities are still evident even after adjustments for socioeconomic status and other access-related factors are taken into account.13

There is often an underlying mistrust of the health care system. Memories of the Tuskegee syphilis study and segregated hospitals remain with older African Americans.3 The combination of mistrust, along with numerous other complex variables, influence issues such as medical decision-making and advance care planning.6,14 Compounding the situation is the fact that health care providers often do not recognize existing biases within systems or themselves.

Ethnicity

Ethnicity refers to individuals with a common ancestry who share a similar sense of historical continuity.7 The values, practices, and beliefs shared by members of the same ethnic group may influence behavior or response.6 It is important to note, however, that although an individual may belong to a particular ethnic group, he or she may not identify strongly with that group.15 Consider intergenerational differences and levels of acculturation. It is not unusual for members of the same family to have very different perspectives on certain issues. Assess each individual’s beliefs and practices rather than assuming that he or she holds the beliefs of a particular group.16 The tendency to assume that an individual will respond in a certain way contributes to stereotyping and can lead to inappropriate interventions.

Gender

Cultural norms dictate specific roles for men and women. The significance of gender is evident in areas such as decision-making, caregiving, and pain and symptom management. It is important to have an awareness of family dominance patterns, and determine which family member or members hold that dominant role. In some families, decision-making may be the responsibility of the male head of the family or eldest son; in others, it may be the eldest female. Discussing prognosis and treatment with an inappropriate member may create significant clashes with the health care team.17

Age

Age has its own identity and culture.1 Age cohorts are characterized by consumer behaviors, leisure activities, religious activities, education, and labor force participation.18 Each group has its own beliefs, attitudes and practices, which are influenced by their developmental stage and by the society in which they live. The impact of a life-limiting illness on persons of differing age groups is often influenced by the loss of developmental tasks associated with that age group. Consider also the cultural impact of age on decision-making, caregiving issues, and barriers to effective pain management.10

Differing Abilities

Individuals with physical disabilities or mental illness are at risk of receiving poorer quality health care. Those with differing abilities constitute a cultural group in themselves and often feel stigmatized. This discrimination is evident in cultures where the healthy are more valued than the physically, emotionally, or intellectually challenged. If patients are unable to communicate their needs, pain and symptom management and end-of-life wishes are not likely to be addressed. Taking time to determine an individual’s goals of care, regardless of differing abilities, and identifying resources and support to improve quality of life is essential.

Sexual Orientation

Sexual orientation may carry a stigma when the patient is gay, lesbian, or transgendered. In palliative care, these patients have unique needs, due to the legal and ethical issues of domestic partnerships, multiple losses that may have been experienced as a result of one’s sexual orientation, and unresolved family issues. Domestic partnerships, sanctioned by many cities and states in the United States, grant some of the rights of traditional married couples to unmarried homosexual couples who share the traditional bond of the family.19 However, many cities and states do not legally recognize the relationship. If legal documents have not been drafted prior to death of a partner, survivorship issues, financial concerns, and lack of acknowledgment of bereavement needs may complicate grief.2

Religion and Spirituality

Religion is the belief and practice of a faith tradition, a means of expressing spirituality. Spirituality, a much broader concept, is the life force that transcends our physical being and gives meaning and purpose.1,20 These terms are often mistakenly
used interchangeably. It should be noted that an individual may be very spiritual, but not practice a formal religion. In addition, those who identify themselves as belonging to a religion do not necessarily adhere to all the practices of that religion. As with ethnicity, it is important to determine how strongly the individual aligns with his or her identified faith and the significance of its practice rituals.

Chaplains, clergy from a patient or family member’s religious group, and ideally their own community clergy are key members of the interdisciplinary team. Often, individuals have misconceptions of the tenets of their own faith, and clergy can help ease spiritual distress.

**Socioeconomic Status**

One’s socioeconomic status, place of residence, workplace, and level of education are important components of one’s cultural identity and play a role in palliative care. For example, those who are socioeconomically disadvantaged face unique challenges when seeking health care and when receiving treatment. Patients and families in a supportive community have increased access to resources at end of life than other more vulnerable populations, such as those in prison and the homeless.

However, regardless of financial status, an estimated 25% of families are financially devastated by a serious terminal illness. Patients experiencing disease progression, or in whom treatment side effects preclude the ability to work, are forced to confront profound losses: loss of work and income, loss of identity, and loss of a network of colleagues. Those who are educationally disadvantaged struggle to navigate the health care system and to access information and support.

In addition to assessing the components of culture previously mentioned, when doing a thorough cultural assessment, it is important to determine communication styles, the meaning of food and food preferences and prohibitions, and death and dying rituals.

**Cultural Considerations Related to Communication**

Awareness of verbal and nonverbal communication styles assists the nurse in establishing trusting relationships, showing respect for variations, and identifying potential communication barriers early to avoid potential conflicts. Communication is an interactive, multidimensional process, often dictated by cultural norms, and provides the mechanism for human interaction and connection.

In any patient, family, or professional encounter, understanding communication styles and norms will help enhance that encounter. Factors to consider include clarifying who the decision-maker in the family is and with whom information should be shared (patient, family, or both). This is a key factor to address early on, as it establishes trust in the patient–provider and family–provider relationships. It is also important to determine the dominant language and dialect spoken and the literacy level of both patient and primary family caregiver(s). Additionally, find out if there are norms related to greetings (e.g., formal/informal; appropriateness of touch, handshake, smile). Attention to acceptable forms of nonverbal communication is as important as knowledge of verbal communication customs; for example, certain gestures, eye contact and silence that may be acceptable in some cultures yet unacceptable in others.

If there is a language barrier, a professionally trained interpreter of the appropriate gender should be contacted. Family members should not be asked to serve as interpreters because this may force them into an uncomfortable role should sensitive issues arise. When using an interpreter, direct all verbal communication to the patient/family, not to the interpreter. Ongoing clarification that information is understood is critical.

Touch can be a powerful communication tool in palliative care; however, although intended to communicate reassurance and caring, touch may invade personal space and privacy, resulting in considerable distress. Norms regarding appropriateness of touching members of the opposite sex are important to note. How close you should be to another, or the concept of personal space is closely related to communication styles. Sitting too close to a patient may be considered intrusive or disrespectful. On the other hand, sitting or standing far away from the patient may communicate disinterest and lack of caring. Asking the individual for guidance on these issues will avoid a great deal of unintended discomfort and avoid misunderstandings.

**Meaning of Food and Nutrition**

Across cultures, there is agreement that food is essential for life, to maintain body function and to produce energy. Food serves another purpose in the building and maintaining of human relationships. It is used in rituals, celebrations, and rites of passage to establish and maintain social and cultural relationships with families, friends, and others. Because of food’s importance for life and life events, a loss of desire for food and subsequent weight loss and wasting can cause suffering for both the patient and family. Culturally appropriate or favorite foods may be encouraged. However, families often need explanations when a patient is no longer able to enjoy favorite foods or family mealtime rituals. It is imperative that the health care team understands the meaning attached to food in a palliative care setting, when decisions regarding the potential burden of providing artificial nutrition and hydration for an imminently dying patient are being discussed.

**Death Rituals and Mourning Practices**

The loss of a loved one brings sadness and upheaval in the family structure across all cultures. Each culture responds to these losses through specific rituals that assist the dying and the bereaved through the final transition from life. Respecting these rituals and customs will have tremendous impact on the healing process for family members following the death.
The tasks of grieving are universal: to accept the reality of the loss, to experience pain of grief, to begin the adjustment to new social and family roles, and to withdraw emotional energy from the dead individual and turn it over to those who are alive.\(^\text{23}\) The expressions of grief, however, may vary significantly among cultures. What is acceptable in one culture may seem unacceptable, or even maladaptive, in another. Recognizing normal grief behavior (versus complicated grief) within a cultural context therefore demands knowledge about culturally acceptable expressions of grief. Important to note is that rituals may begin before death and may last for months or even years after death. Some may value being present at the time of death. Insure that any required spiritual, religious, or cultural practices are performed and that appropriate care of the body after death is carried out.

Cultural Competence

Cultural competence refers to a dynamic, fluid, continuous process of awareness, knowledge, skill, interaction, and sensitivity.\(^\text{3}\) Cultural competence is an ongoing process, not an end point. It is more comprehensive than cultural sensitivity, implying not only the ability to recognize and respect cultural differences, but also to intervene appropriately and effectively.\(^\text{3,26,27}\) Five components essential in pursuing cultural competence are cultural awareness, cultural knowledge, cultural skill, cultural encounter, and cultural desire.\(^\text{28}\)

Integrating cultural considerations into palliative care requires first and foremost that the nurse becomes aware of how one’s own values, practices, and beliefs influence care.\(^\text{26,28,29}\) Cultural awareness begins with an examination of one’s own heritage, family’s practices, experiences, and religious or spiritual beliefs.\(^\text{29,30}\) Each nurse brings his or her own cultural and philosophical views, education, religion, spirituality, and life experiences to the care of the patient and family. Cultural awareness challenges the nurse to look beyond his or her ethnocentric view of the world, asking the question “How are my values, beliefs, and practices different from the patient and family?” rather than “How is this patient and family different from me?”\(^\text{31}\) Exploring one’s own beliefs will raise an awareness of differences that have the potential to foster prejudice and discrimination and limit the effectiveness of care.\(^\text{29}\) Often this exploration identifies more similarities than differences (Figure 34–1). The universal aspects of life, family, trust, love, hope, understanding, and caring unite us all.\(^\text{32}\)

Acquiring knowledge about different cultural groups is the second component to gaining cultural competence, but knowledge alone is insufficient in providing culturally appropriate care. Yet, how does one attempt to gain knowledge and understanding of so many diverse cultures? No one can expect to have in-depth knowledge of all cultural variations of health and illness beliefs, values, and norms. A suggested strategy is to identify the most common ethnic group/cultures living in the nurse’s community, and to integrate a basic understanding of norms and practices impacting issues likely to arise in palliative and end-of-life situations. Involve community members, organizations, faith communities, and leaders in a shared understanding of needs and concerns. Knowledge gained of a particular group should serve only as a guide to understanding the unique cultural needs of the patient and family that comes through individualized assessments. Other resources, such as cultural guides, literature and web-based resources are available to assist the nurse in acquiring knowledge about specific groups. Table 34–2 lists several useful web-based resources.

Cultural skill is the third component of cultural competency. Skills in cultural assessment, cross-cultural communication, cultural interpretation, and appropriate intervention can be learned. Multiple tools are available to assess cultural behavior and beliefs. Key assessment questions, applicable in the palliative care setting, will help the nurse address the patient’s and family’s needs in a culturally sensitive manner.\(^\text{23}\)

Cultural Assessment

Cultural assessments involve questions that necessitate the development of a trusting relationship. When meeting the patient and family early in the disease trajectory, the palliative care clinician is able to establish trust. Often, though, the palliative care nurse may not have the luxury of time. Ideally, the patient’s primary care team would have completed the assessment and communicated information gleaned from the assessment across settings.

When the timing of the assessment cannot be planned, inquiries of the patient or family can be helpful in assisting the nurse to gain the most helpful information for the situation at hand. Checklists do not necessarily build trust. Instead, asking the patient, or the family member to tell you about him or herself or the family, and then listening to those narratives can reveal many of their beliefs, values, and concerns. The speaker may give you clues that trigger important questions to ask so that you are able to clarify patient and family needs and goals. Examples of trigger questions are provided in Table 34–3.

Selected Palliative Care Issues Influenced by Culture

Cultural considerations impact all aspects of palliative care: assessment, planning, and implementation of care. This section focuses on cultural considerations regarding decision-making, pain, and symptom management.

Medical Decision-Making

Over the past 35 years in the United States, ethical and legal considerations of decision-making have focused on patient
CULTURAL KNOWLEDGE AND BELIEFS

1. List two cultural groups to which you belong (e.g., ethnicity, religion/spirituality).

   ________________________________________________________________
   ________________________________________________________________

   a. List three values that you attribute to each group listed above.

   ________________________________________________________________
   ________________________________________________________________
   ________________________________________________________________

   b. List three rituals that you practice that have been learned from each cultural group.

   ________________________________________________________________
   ________________________________________________________________
   ________________________________________________________________

2. Write down the first names of the 10 people with whom you spend the most time on a weekly basis. In the blank spaces below write down how many of them (0-10) differ from you in terms of:

   Socioeconomic status ____________________  Health ____________________
   Ethnicity _______________________________  Race ______________________
   Gender _________________________________  Spirituality __________________
   Nationality ______________________________  Sexual orientation ____________
   Cognitive abilities ______________________  Physical abilities ____________
   Age (5+/- years) __________________________  Mental abilities ____________

3. Rank 1 to 5 the most common resources you use to learn about people from other cultural groups (1 = most frequent; 5 = least frequent).

   ______ Television shows
   ______ Ongoing personal relationships
   ______ Classroom presentations
   ______ Radio shows
   ______ Textbooks
   ______ Clients in clinical area
   ______ Research articles
   ______ Movies
   ______ Work relationships
   ______ Cultural events
   ______ Newspapers
   ______ Other (list)

4. Rank from 1 to 5 the most common reasons you are reluctant to or do not interact with people from other cultural groups (1 = most common; 5 = least common).

   ______ Don’t know where to meet people
   ______ Fear of bodily harm from animals
   ______ Family or peer pressure
   ______ Fear of rejection
   ______ Not interested
   ______ Fear of offending them
   ______ Past experiences
   ______ Language barriers
   ______ Nothing in common
   ______ Other (list)

Figure 34-1. Cultural knowledge and beliefs: a self-assessment questionnaire. (Source: JoAnne Banks-Wallace, PhD, RN, The University of Missouri, Sinclair School of Nursing, Columbia, MO. ONS Multicultural Tool Kit.)
This focus replaced the more paternalistic approach of decision-making as solely the physician’s responsibility, with an approach that emphasizes a model of shared responsibility with the patient’s active involvement. The Patient Self-Determination Act of 1991 sought to further clarify and to protect an individual’s health care preferences with advance directives. The principle of respect for patient autonomy points to a patient’s right to participate in decisions about the care he or she receives. Associated with this is the right to be informed of diagnosis, prognosis, and the risks and benefits of treatment in order to make informed decisions.

Inherent in the movement for patient autonomy is the underlying assumption that all patients want control over their health care decisions. Yet, in fact, for some individuals, patient autonomy may violate the very principles of dignity and integrity it proposes to uphold.

This European-American model of patient autonomy has its origin in the dominant culture, a predominantly white middle-class perspective that does not take into consideration diverse cultural perspectives. Emphasis on autonomy as the guiding principle assumes that the individual, rather than the family or other social group, is the appropriate decision-maker.
However, in many non-European American cultures, the concept of interdependence among family and community members is more valued than individual autonomy.\textsuperscript{33,37} Cultures that practice family-centered decision-making, such as Asian and Hispanic cultures, may prefer that the family, or perhaps a particular family member rather than the patient, receive and process information.\textsuperscript{17} Patient autonomy may not be seen as empowering, but, rather, may seem burdensome for patients who are too sick to have to make difficult decisions.\textsuperscript{31} The label of “truth-telling” itself is misleading. While full disclosure may not be appropriate, it is never appropriate to lie to the patient. If the patient does not wish to receive information and/or telling the patient violates the patient’s and family’s cultural norms, the health care provider may, in fact, not be respecting the patient’s right to autonomously decide not to receive the information. Some cultures believe that telling the patient he has a terminal illness strips away any and all hope and causes needless suffering, and may indeed hasten death.\textsuperscript{3,12,38,39}

The nurse must consider the harm that may occur when the health system or providers violate cultural beliefs and practices.\textsuperscript{17} Assessing and clarifying the patient and family’s perspectives, values, and practices may prevent a cultural conflict.\textsuperscript{33} The nurse is in a key position to advocate these critical patient and family issues (see Table 34–3 for examples of

<table>

<tbody>
<tr>
<td><strong>Key Cultural Assessment Questions</strong></td>
</tr>
</tbody>
</table>

*Formal cultural assessments are available for the nurse to use (see resources in Table 34–2). Remember that a checklist does not always instill trust. Below are some suggestions for ascertaining key cultural preferences from both patients and family caregivers.*

- Tell me a little bit about yourself (for families, e.g., your mother, father, sister, brother, etc.)
  - Where were you born and raised? (If an immigrant: How long have you lived in this country?)
- What language would you prefer to speak?
- Is it easier to write things down, or do you have difficulty with reading or writing?
- Whom do you go to for support (family, friends, community, religious or community leaders)?
- Is there anyone we should contact to come to be with you?
- I want to be sure I’m giving you all the information you need. What do you want to know about your condition? Whom should I speak to about your care?
- Whom do you want to know about your condition?
- How are decisions about health care made in your family? Should I speak directly with you, or is there someone else I should be discussing decisions with?
- *(Address to patient or designated decision maker.)* Tell me about your understanding of what has been happening up to this point? What does the illness mean to you?
- We want to work with you to be sure you are getting the best care possible, and that we are meeting all your needs. Is there anything we should know about any customs or practices that are important to include in your care?
- Many people have shared that it is very important to include spirituality or religion in their care. Is this something that is important for you? Our chaplain can help contact anyone that you would like to be involved with your care.
- We want to make sure we respect how you prefer to be addressed, including how we should act. Is there anything we should avoid? Is it appropriate for you to have male and female caregivers?
- Are there any foods you would like or that you should avoid?
- Do you have any concerns about how to pay for care, medications or other services?

**Death Rituals and Practices**

- Is there anything we should know about care of the body, about rituals, practices, or ceremonies that should be performed?
- What is your belief about what happens after death?
- Is there a way for us to plan for anything you might need both at the time of death and afterward?
- Is there anything we should know about whether or not a man or a woman should be caring for the body after death?
- Should the family be involved in the care?
questions to ask). By asking how decision are made, and whether or not the patient wishes to be involved in both being told information or participating in the decision-making process, patient autonomy is respected, and individual beliefs and values are honored.14

Withholding and Withdrawing

Another issue with the potential for cultural conflict is decision-making regarding withholding and withdrawing of life-sustaining treatments. Deciding to withhold or withdraw life-sustaining treatment is difficult because inherent in the decision is that the patient will most likely die.24 Attitude surveys looking at initiating and terminating life support have demonstrated differences among several ethnic groups. When making difficult decisions, family members often feel that by agreeing to withdrawal of life support, they are, in fact, responsible for the death of their loved one. Recognize also that the words used in these decisions, including “do not resuscitate,” all have negative connotations and involve the removing of something or the withholding of a particular intervention. Research suggests that groups including African Americans, Chinese Americans, Filipino Americans, Iranian Americans, Korean Americans, and Mexican Americans were more likely to start and to continue life support when such measures were felt by the health care team to be futile than were European Americans.46 Because many ethical conflicts arise from differences in patients’, families’, and providers’ values, beliefs, and practices, it is critical that individual members of the health care team be aware of their own cultural beliefs, understand their own reactions to the issue, and be knowledgeable about the patients’ and families’ beliefs to address the conflict.33

The Experience of Pain

Pain is a highly personal and subjective experience. Pain is whatever the person says it is, and exists whenever the person says it does.25 Culture plays a role in the experience of pain, the meaning of pain, and the response to pain. A biocultural model of pain suggests that social learning from family and group membership can influence the psychological and physiological processing of pain, which then affects the perception and modulation of pain.42

Strong beliefs about expressing pain and expected pain behaviors exist in every culture.43 Pain tolerance varies from person to person and is influenced by factors such as past experiences with pain, coping skills, motivation to endure pain, and energy level. Western society appears to value individuals that exhibit a high pain threshold.44 As a result, those with a lower threshold, who report pain often, may be labeled as “difficult patients.”

Pain assessment should be culturally appropriate, using terms that describe pain intensity across most cultural groups. “Pain,” “hurt,” and “ache” are words commonly used across cultures. These words may reflect the severity of the pain, with “pain” being the most severe, “hurt” being moderate pain, and “ache” being the least severe.44 Focus on the words the patient uses to describe pain. To help facilitate an understanding of the severity of the pain experienced by someone who does not speak English, use pain rating scales that have been translated into numerous languages.44 While it is important to base the assessment on the patient’s self-report of pain intensity, it may be necessary to rely on nonverbal pain indicators such as facial expression, body movement, and vocalization to assess pain in the nonverbal, cognitively impaired patient, the older adult, or the infant, who are all at risk for inaccurate assessment and undertreatment of pain.45–47

Both cultural bias in pain reports and gender biases have been identified and documented.13 Studies of gender variations in pain response have identified differences in sensitivity and tolerance to pain, and willingness to report pain.46–51 Studies reveal that Hispanics, African Americans, and females are less likely to be prescribed opioids for pain.47,51

Incorporating culturally appropriate nondrug therapies may improve the ability to alleviate pain. Healing practices specific to cultures should be offered to the patient and family.51 Herbal remedies, acupuncture, and folk medicines should be incorporated into the plan of care if desired. Keep in mind that certain nondrug approaches, such as hypnosis and massage, may be inappropriate in some cultures.44

Symptom Management

Similar to pain management, symptoms have cultural meanings associated with them that reflect cultural values, beliefs, and practices. Assessment and management of such commonly occurring symptoms in palliative care as fatigue, dyspnea, depression, nausea and vomiting, and anorexia/cachexia should be implemented within a cultural framework.

As noted earlier, it is important to understand the health and illness beliefs of the cultural groups living in your community. Table 34–4 lists cultural considerations for pain and symptom management for selected groups. Of note, there is a dearth of information in the literature regarding health and illness beliefs in the Caucasian, or what is often referred to as the European-American population. This group, as with other ethnic groups, migrated from numerous countries of origin. The reader is reminded that the groups listed in Table 34–4 also immigrated from various geographic areas. Therefore, the list serves as a guide only and does not replace individual assessment. The nurse recognizes guides as offering information based on generalizations, and that making assumptions without validating their significance to the individual and family may lead to harmful stereotyping.33

Summary

Given the changing population of the United States, we as nurses must advocate for the integration of cultural considerations in providing comprehensive palliative care. It is imperative that
each of us moves beyond our own ethnocentric view of the world to appreciate and respect the similarities and differences in each other. We are challenged to embrace a better understanding of various perspectives. Becoming culturally competent first requires an awareness of how one's own cultural background impacts care. In addition, acquiring knowledge about cultures and developing skill in cultural assessment are essential to improving care to patients with life-limiting illnesses and their families.

This chapter encourages nurses to integrate cultural assessment and culturally appropriate interventions into palliative care. It is the hope of the authors that readers will enrich their practice by seeking new knowledge about different cultures through available resources and, most importantly, by using the most valuable resources on cultural considerations we have—our patients and their families.

Key Points

- The majority of people who suffer from chronic disease are elderly.
- The trajectory of illness for the elderly is usually one of progressive loss of independence, with the development of multiple comorbid problems and symptoms.
- The last years of a frail elderly person's life are often spent at home in the care of family, with approximately 50% to 60% of the elderly dying in a hospital or long-term care facility.
- Evidence suggests that the end of life for many elderly is characterized by poor symptom control, inadequate advanced care planning, and increased burden on caregivers.
- Clinicians caring for the elderly often lack skills in providing palliative and end-of-life care.

Aging is a normal process of life, not a disease, and infirmity and frailty do not always have to accompany being old. It is expected that most of us will live well into our 70s or 80s, and the aging of the population is projected to continue well into the 21st century. Projected growth for the elderly population is staggering. During the next 20 years, the fastest-growing segment of the population will be in the group aged 85 years and older. During the past decades, this increase in life expectancy has been mainly due to improvements in sanitation and infectious-disease control through vaccinations and antibiotics. Presently, the older population is growing older because of positive trends in the treatment of chronic diseases—cardiovascular and neurological, as well as cancer. This “swelling” of the older segment of the population reinforces the need for nurses, physicians, and all health care professionals to understand the special palliative care needs of the elderly. In our society, the majority of people who have chronic disease are elderly. One of the major differences from younger groups in treating illness in the elderly population is the need for extensive family support and care during the last weeks and months of life.

Comorbidity and Disability

The elderly have many comorbid medical conditions that contribute an added symptom burden to this palliative care population. The presence of existing comorbidities and disabilities renders them more susceptible to the complications of new illnesses and their treatments. The presence of chronic medical conditions is associated with disability and increased health care use, including institutionalization and hospitalization in the elderly (Table 35–1). Forty percent of community-dwelling adults older than 65 report impairment in their daily activities secondary to chronic medical conditions. Sixteen percent of adults older than 65 report impairment in walking, increasing...
to more than 32% in those older than 85. Comorbidity is highly prevalent in people over 65 years. In the United States, 49% of noninstitutionalized people over 60 have two or more chronic conditions. Much higher percentages are seen in adults older than 65 who are living in a nursing home or who are hospitalized.1–11

Sites of Residence and Place of Death

Sixty-six percent of older noninstitutionalized persons live in a family setting; this decreases with increasing age. Three out of every five women older than 85 live outside of a family arrangement. Rates of institutionalization are estimated to be 4% to 5% in the United States; this increases to 23% in the over-85 population. The wide range of care settings for the elderly is reflected in the sites of death of the elderly.8,12–15

Over the past 100 years, the site of death has shifted from the home to institutions. Data from the National Institute on Aging’s Survey of the Last Days of Life (SLDOL) indicate that 45% of the elderly who died spent the night prior to death in a hospital and 24% in a nursing home, and 30% died at home.15a There was a significant drop in the proportion of patients in the older age group for both men and women who died in hospitals and an increase in proportions dying at home or nursing homes. Almost one third of older women died in nursing homes. Interestingly, the National Mortality Follow-Back Survey reported that only 8.7% of decedents were receiving home hospice, and less than 0.5% were receiving inpatient hospice care.8–9

In several studies, cancer and dementia are predictive of death at home rather than in institutions. Death in hospice appears to correlate with the local availability of hospice beds, as well as a diagnosis of cancer. For patients with a preference for death at home, the availability of home visits by physicians correlates with a higher rate of death at home. In patients expressing an initial wish to die at home, caregiver burnout and unrelieved symptoms are predictive of death in hospitals and hospice.12–15 The available data suggest that with limited increase in the allocation of nursing support, dying patients’ wishes to die at home can be met. Elderly women are more than twice as likely to be living alone than are elderly men. More than half of women 75 and older live alone.12–15 Those living alone rely more heavily on the presence of social supports and assistance for the provision of health care.12–15

Palliative Care in Nursing Homes

End-of-life care in long-term care settings is described in greater detail in Chapter 40. It is estimated that of those who turned 65 years old in 1990, 43% will enter a nursing home before they die.16 Because the fastest-growing segment of the population is those over 85 years, it is likely that these individuals will require long-term care in these settings. Pain management and end-of-life care in nursing homes represent management of the frailest individuals, often with minimal physician involvement. As many as 45% to 80% of nursing home residents have pain that contributes significantly to impaired quality of life.17 Most mild pain in nursing homes is related to degenerative arthritis, low-back disorders, and diabetic and postherpetic neuropathy. Cancer pain accounts for the majority of severe pain.18

Barriers to palliative care in the nursing home include institutional, patient, and staff-related barriers (Table 35–2). Data from nursing homes suggest that as many as 30% to 80% of nursing home residents receive inadequate pain management.19–25
In one study comparing analgesic management of dying patients in a nursing home enrolled and not enrolled in Medicare Hospice program, 15% percent of hospice residents and 25% of nonhospice residents in daily pain received no analgesics; 51% of hospice residents and 33% of nonhospice residents received regular treatment for pain. These findings suggest that for nursing home residents in pain, analgesic management is better for hospice patients, but for many residents, pain management is sporadic and often inconsistent with American Medical Directors Association Guidelines.26 Many other obstacles to palliative care have been identified, including lack of communication among decision-makers, lack of agreement on a course for end-of-life care, failure to implement a timely end-of-life care plan, and failure to recognize treatment futility.27 Only about half of nursing home residents have do-not-resuscitate (DNR) orders, fewer than one in five have advance directives, and fewer (14%) have living wills and do-not-hospitalize directives (4%).28–30 One of the most troublesome concerns expressed by staff who care for nursing home residents is the difficulty in assessing pain in the cognitively impaired elderly resident.

Approximately 90% of the 4 million Americans with dementia will be institutionalized before death.31 One of the barriers to end-of-life care in this population is that advanced dementia is often not viewed as a terminal condition. Because of this, palliative care often is not initiated until the final stages of life. In one retrospective study using the data from the Minimum Data Set,32–33 1784 residents with advanced dementia and 918 residents with terminal cancer were compared. Residents with advanced dementia were older, lived longer, and had higher activity of living scores than the terminal cancer residents. Six months after admission to the nursing home, only 20% of the residents with advanced dementia were perceived as having a life expectancy of less than 6 months. At the last assessment before death, only 4.1% were recognized as having a prognosis under 6 months; 55% had a DNR order, compared with 86.1% of the cancer patients.34 With respect to nonpalliative interventions, residents dying with advanced dementia experienced more frequent uncomfortable or aggressive interventions at the end of life; 25% died with a feeding tube, 11% with restraints, and 10.1% with intravenous (IV) therapy. These findings suggest that palliative care for nursing home residents with advanced dementia is suboptimal, and encourages use of educational strategies to promote palliative care to these patients.

Economic Considerations in Caring for the Elderly

The higher rates of disability and comorbidity in the elderly, requiring the provision of long-term residential care as well as home care, result in considerable costs to the health care.

Health Care Financing Administration data indicate that 6% to 8% of Medicare enrollees die annually and account for 27% to 30% of annual Medicare expenses.35 However, spending on aggressive interventions is not a major component of the hospital costs incurred in the dying elderly. Only 3% of Medicare beneficiaries who die sustain high costs associated with aggressive interventions such as surgery, chemotherapy, or dialysis.

While hospital costs in the last days of life are lower for the oldest old, the percentage of Medicare and Medicaid expenditure for nursing home care rises from 24% for the young-old...
(65 to 74 years), to 62% for the oldest old (over 85 years).36–38

Most required residential care occurs in the last days of life.

**Determination of Prognosis and the Provision of Palliative Care**

Providing palliative care to elderly patients is limited by the uncertain prognoses of many chronic illnesses in this population (congestive heart failure, chronic obstructive pulmonary disease [COPD], cerebrovascular disease, dementia). Because of the difficulty to accurately prognosticate and many other factors, most patients who have fatal illnesses do not use the Medicare hospice benefit until shortly before death.39 Even the most complex prognostic scoring systems, such as the APACHE (Acute Physiology Age Chronic Health Evaluation), provide little information for the likelihood of an individual patient’s death.39

The uncertain prognoses of chronic nonmalignant medical conditions can affect clinical decision-making. It may also lead to overuse of health care resources in acute care settings, even when death is imminent. An analysis of Medicare claim data for 6451 elderly hospice patients demonstrated that median survival after enrollment was only 36 days, with 15.6% dying within 7 days.40–42

**Advance Directives and Decision-Making**

Advance directives are especially important in elderly patients who are at high risk of morbidity and mortality. The presence, stability, and willingness to discuss advance care planning appears to be dependent upon several factors, including communication issues, value differences, cultural issues, ethnicity, and mental capacity.43,44 In one study of advance care planning among nursing home residents, two variables were associated with the reduced likelihood of having DNR and do-not-hospitalize orders or restricting feeding, medication or other treatment: African-American ethnicity and less time in the facility.41

Many references in the literature support the notion that a patient’s prior decision regarding treatment choices accurately reflects future choices,45–48 however, not all studies support that. One prospective longitudinal study of 65 nursing home residents assessed stability of residents’ preferences for life-sustaining interventions and evaluated factors that potentially affect these decisions.49 Resident preferences changed over a 2-year period. Overall, a majority of participants consistently desired cardiopulmonary resuscitation, whereas somewhat fewer than half desired medical hydration and nutrition. As time progressed, a greater proportion of individuals favored medical hydration and nutrition. Because this study was of institutionalized residents who routinely witness the administration of hydration and nutrition to fellow residents, the authors concluded that such interventions become commonplace and are easily accepted by other residents. This practice, they believe, has an influence on the resident’s decision to accept hydration.

**Family/Caregiver Issues**

**Who Are the Caregivers for the Elderly?**

The term caregiver refers to anyone who provides assistance to someone else who needs it. “Informal caregiver” is a term used to refer to unpaid individuals, such as family members and friends, who provide care. These persons can be primary or secondary caregivers, full or part time, and can live with the person being cared for or live separately. “Formal caregivers” are volunteers or paid care providers associated with a service system. Estimates vary on the numbers of caregivers in the United States.

According to the most recent National Long Term Care Study (NLTCS), more than 7 million people are informal caregivers, defined here as spouses, adult children, other relatives, and friends who provide unpaid help to older people with at least one limitation in their activities of daily living. An estimated 15% of American adults are providing care for seriously ill or disabled adults.50 Of these, an estimated 12.8 million Americans need assistance to carry out activities such as eating, dressing, and bathing. About 57% are aged 65 or older (7.3 million). Spouses accounted for about 62% of primary caregivers. Approximately 72% of caregivers are female.51 The majority of caregivers provide unpaid assistance for 1 to 4 years, 20% provide care for 5 years or longer.51

According to the 2000 National Hospice Care Survey (NHCS), 42% of patients enrolled in hospice programs were women and 33% were men. The majority (81%) were 65 years or older, and a significantly larger proportion of women than men were 85 years of age or older. Men were more likely to have a spouse as their primary caregiver, while women were more likely to be cared for by a child or child-in-law. The most common diagnosis for most of the hospice care patients included neoplasm, heart disease, and COPD.52

**Involving Family in Caregiving for the Elderly: What Is the Burden?**

The burden of caregiving has been well documented in the literature and includes a greater number of depressive symptoms, anxiety, diminished physical health, financial problems, and disruption in work. The amount of concrete needs the patient has strongly relates to family and caregiver psychological distress and burden of care.51 Elderly patients who are dying require varying levels of assistance with personal care, meal preparation, shopping, transportation, paying bills, and submitting forms related to health care. The level of physical care may be tremendous and include bathing, turning and positioning, wound care, colostomy care, suctioning, medication administration, and managing incontinence. If the patient is confused or agitated, the strain is even greater, as 24-hour care may be necessary. In the palliative care setting, where the treatment goals are supportive and often include management of symptoms such as pain, respiratory distress, and delirium,
the patient is frequently confined to home, with a greater burden placed on the live-in spouse or child.

In one study comparing the impact of caregiving in curative and palliative care settings, two study groups were evaluated—267 patients received active, curative treatment, and 134 patients received palliative care through a local hospice. Patients in the palliative care group were more physically debilitated and had poorer performance status. The mean age was 59.7 for the curative group and 57.9 for the palliative care group. Caregiver quality-of-life measures demonstrated that family caregivers of patients receiving palliative care had lower quality-of-life scores and worse overall physical health than family caregivers of patients receiving curative care. Families with low socioeconomic status and those with less education were more distressed by the patient’s illness.

Transitions in spousal caregiving have been investigated in respect to the level/intensity of caregiving and its impact on the overall health of the caregiver. In 428 subjects who were assessed at four intervals over a 5-year period, those who transitioned to heavy caregiving had more depressive symptoms than those who transitioned into moderate caregiving. Heavy caregivers scored higher in the number of health-risk behaviors between the second and third observations, concluding that these outcomes become worse over time.

Family caregivers of people with dementia face particularly stressful demands because of the exhaustive phase of prolonged dependence. In one study, two goals of the caregiving to patients with dementia experience were looked at: the description of the caregiving experience, and the short- and long-term responses to bereavement. Two hundred sixty five in-home caregivers were assessed at 6-, 12-, and 18-month intervals. The mean length of caregiving was 3 years. More than one half of the caregivers reported that they felt they were on duty 24 hours a day, 48% had to reduce their work load, and 38% had to stop work entirely.

In another study of 231 caregivers of cancer patients who were at home, the goals were to evaluate family caregiver’s quality of life, financial burden, and experience of managing cancer pain in the home. Family caregivers scored worse in areas of coping difficulty, anxiety, depression, happiness, and feeling in control. In areas of physical well-being, the greatest problems were sleep changes and fatigue. Other quality-of-life disruptions included interference with employment, lack of support from others, isolation, and financial burden. The estimated average time spent caregiving was more than 12 hours per day; the estimated time for pain management was more than 3 hours per day. Family caregivers reported worse outcomes than patients did in their perception of the pain intensity, pain distress to themselves, feeling able to control the pain, and family concern about pain in the future. Caregivers reported fear of future pain, fear of tolerance, and concern about addiction and harmful effects of analgesics. The authors concluded that educational programs in pain management are needed and that further educational efforts should also address the emotional aspects of managing cancer pain in the home. Interventions directed toward improving the quality of life of direct caregivers include educational programs, improvement in home care supports, psychoeducational programs, and improved access to health care professionals who provide symptom management and end-of-life care.

Family grief therapy during the palliative phase of illness has also improved the psychosocial quality of life of caregivers. Kissane and colleagues used a screening tool to identify dysfunctional family members and relieve distress through a model of family grief therapy sessions. Smeenk and colleagues demonstrated improved quality of life of direct caregivers after implementation of a transmural home care intervention program for terminal cancer patients. Macdonald demonstrated that massage as a respite intervention for caregivers was successful in reducing physical and emotional stress, physical pain, and sleep difficulties. This nonpharmacological and noninvasive intervention is highly valued and accepted by caregivers because of its simplicity and beneficial effects.

Pharmacological Considerations

Pharmacological intervention is the mainstay of treatment for symptom management in palliative care of the elderly patient. Knowledge of the parameters of geriatric pharmacology can prevent serious morbidity and mortality when multiple drugs are used to treat single or multiple symptoms, or when, in the practice of chronic pain management, trials of sequential opioids (opioid rotation, or opioid switch) are used.

Pharmacokinetics

The four components of pharmacokinetics are absorption, distribution, metabolism, and excretion. In the absence of malabsorption problems and obstruction, oral medications are well tolerated in the elderly population. With aging, there is some decrease in gastric secretion, absorptive surface area, and splanchnic blood flow. Most studies show no difference in oral bioavailability—the extent to which a drug reaches its site of action. There is little literature on the absorption of long-acting drugs in the elderly, including controlled or sustained-release opioids, and transdermal opioids commonly used in the treatment of chronic cancer pain in the elderly patient. Controlled-release dosage forms are generally more appropriate with drugs that have short half-lives (less than 4 hours) and include many of the shorter-acting opioids, including morphine and hydromorphone. Generally, it is safer to use opioids that have shorter half-lives in the elderly cancer patient.

Distribution refers to the distribution of drug to the interstitial and cellular fluids after it is absorbed or injected into the bloodstream. There are several significant physiological factors that may influence drug distribution in the elderly palliative care patient. An initial phase of distribution reflects cardiac output and regional blood flow. The heart, kidneys, liver, and brain receive most of the drug after absorption. Delivery to fat, muscle, most viscera, and skin is slower; it may take several
hours before steady-state concentrations are reached. Although
cardiac output does not change with age, chronic conditions,
including congestive heart failure, may contribute to a decrease
in cardiac output and regional blood flow.

This second phase of drug distribution to the tissues is
highly dependent upon body mass. Body weight generally
decreases with age, but more importantly, body composition
changes with age. Total body water and lean body mass decrease,
while body fat increases in proportion to total body weight.
The volume-of-distribution changes are mostly for highly
lipophilic and hydrophilic drugs, and the elderly are most sus-
cetible to drug toxicity from drugs that should be dosed on
ideal body weight or lean body weight. Theoretically, highly
lipid-bound drugs, for example, long-acting benzodiazepines
and transdermal fentanyl, both commonly prescribed to el-
derly patients, may have an increased volume of distribution
and a prolonged effect if drug clearance is constant. Water-
soluble drugs (e.g., digoxin) may have a decreased volume of
distribution and increased serum levels and toxicity if initial
doses are not conservative. To avoid possible side effects in a
frail elderly patient, it may be safe to start with one half the
dose usually prescribed for a younger patient.

Another host factor that influences drug distribution is
plasma protein concentrations.62,63 Most drugs, including anal-
gesics, are extensively bound to plasma proteins. The propor-
tion of albumin among total plasma proteins decreases with
frailty, catabolic states, and immobility, commonly seen in
many elderly patients with chronic conditions. A decrease in
serum albumin can increase the percentage of free (unbound)
drug available for pharmacological effect and elimination. In
this setting, standard doses of medications lead to higher lev-
els of free (unbound) drug and possible toxicity.

The liver is the major site of drug metabolism. Hepatic
metabolism of drugs is dependent on drug-metabolizing
enzymes in the liver. The hepatic microenzymes are respon-
sible for this biotransformation. With advanced age, there is
a decrease in liver weight by 20% to 50% and liver volume
decreases by approximately 25%.64 In addition, a nondrug
marker for hepatic functional mass, galactose clearance, is
decreased by 25% in advanced age. Associated with these
changes in liver size and weight is a decrease in hepatic blood
flow, normalized by liver volume. This corresponds to a decrease
in liver perfusion of 10% to 15%. Drugs absorbed from the
intestine may be subject to metabolism and the first-pass effect
in the liver, accounting for decreased amounts of drug in the
circulation after oral administration. The end result is decreased
systemic bioavailability and plasma concentrations.64

The process of biotransformation in the liver is largely
dependent upon the P-450 cytochrome. During biotransfor-
mation, the parent drug is converted to a more polar meta-
bolite by oxidation, reduction, or hydrolysis. The resulting
metabolite may be more active than the parent drug. The
cytochrome P-450 has been shown to decline in efficiency with
age. These altered mechanisms of drug metabolism should be
considered when treating the elderly palliative care patient
with opioids, long-acting benzodiazepines, and neuroleptics.

The effect of age on renal function is quite variable. Some
studies show a linear decrease in renal function, amounting to
decreased glomerular function; other studies indicate no change
in creatinine clearance with advancing age.64 Renal mass
decreases 25% to 30% in advanced age, and renal blood flow
decreases 1% per year after age 50.64 There are also decreases
in tubular function and reduced ability to concentrate and
dilute the urine. In general, the clearance of drugs that are
secreted or filtered by the kidney is decreased in a predictable
manner.

For example, delayed renal excretion of meperidine’s
metabolite, normeperidine, may result in delirium, central ner-
vous system (CNS) stimulation, myoclonus, and seizures.
Meperidine is not recommended for chronic administration
in any patient but is of special concern for elderly patients with
borderline renal function. Other drugs that rely on renal excre-
tion include nonsteroidal antiinflammatory agents, digoxin,
aminoglycoside antibiotics, and contrast media.

Medication Use in the Elderly: Problems with Polypharmacy

Older individuals use three times more medications than younger people do. They account for approximately 25% of physician visits and approximately 35% of drug expenditures. Elderly patients are more likely to be prescribed inappropriate medications than younger patients are.\(^6\) Advancing age alone does not explain the risk of adverse drug reactions, and polypharmacy is a consistent predictor. As noted earlier, in the palliative care setting, elderly patients often have more than one comorbid medical condition, necessitating treatment with many medications, which places them at greater risk of adverse drug reactions. In addition, new medications not only place the elderly at risk of adverse drug reactions, they also increase the risk of significant drug interactions. For example, the addition of an antacid to an elderly patient already on corticosteroids for bone pain may significantly decrease the oral corticosteroid effect due to decreased absorption.

Understanding pharmacodynamics in relationship to age-related physiological changes can assist the clinician in evaluating the effectiveness and side-effect profile in the elderly palliative care patient (Table 35–3). When multiple drugs are used to treat symptoms, the side-effect profile may increase, potentially limiting the use of one or more drugs. For example, when using an opioid and a benzodiazepine in treating chronic pain and anxiety in the elderly patient, excessive sedation may occur, limiting the amount of opioid that can be administered. Table 35–4 outlines the components of a comprehensive medication assessment in the elderly palliative care patient.

Symptom Management During the Last Weeks of Life: Special Concerns

Numerous studies have evaluated symptoms during the last weeks of life and indicate that patients experience a high degree of symptom distress and suffering. In one study by Seale and Cartwright,\(^6\) there were age-related differences in the incidence of mental confusion, loss of bladder and bowel control, as well as seeing/hearing difficulties. There was no age-related difference in patients reporting pain (72%), trouble breathing (49%), loss of appetite (47%), drowsiness (44%), and other symptoms, including sleeplessness, constipation, depression, vomiting, and dry mouth.

Studies have documented the most prevalent and difficult-to-manage symptoms in dying patients, including pain, dyspnea, and confusion states.\(^6\) In one evaluation of the symptom burden of seriously ill hospitalized patients in five tertiary care facilities, pain, dyspnea, anxiety, and depression caused the greatest symptom burden.\(^2\) In this study, patients for whom hospital interviews were not available had more dependencies in daily living and more comorbidities, were older, sicker, poorer, and more often had respiratory failure and multiorgan system failure.

The complex symptomatology experienced by elderly patients, especially those with cancer and multiple comorbidities, demands that an aggressive approach to symptom assessment and intervention be used. Devising a palliative plan of care for the elderly patient who is highly symptomatic or who is actively dying requires ongoing communication with the patient and family; assessment of patient and family understanding of goals of care and religious, cultural and spiritual beliefs; access to community agencies; psychological assessment; and patient and family preferences regarding advance directives. Dimensions of a palliative care plan for the elderly are outlined in Table 35–5. The management of three prevalent and distressing symptoms experienced by the elderly at the end of life—dyspnea, pain, and delirium—is discussed below. Each of these symptoms is discussed in greater detail in other chapters.

**Dyspnea**

Dyspnea may be one of the most frightening and difficult symptoms an elderly patient can experience. A subjective feeling of breathlessness or the sensation of labored or difficult
breathing, dyspnea contributes to severe disability and impaired quality of life. Dyspnea and fear of dyspnea produce profound suffering for dying patients and their families. This section will outline the special needs for elderly patients, with a focus on physiological factors that increase the risk of dyspnea.

**Physiological Correlates in the Elderly That Increase Risk of Dyspnea**

The effects of aging produce a clinical picture in which respiratory problems can develop. With aging, the elastic recoil of the lungs during expiration is decreased due to less collagen and elastin. Alveoli are less elastic and develop fibrous tissue. The stooped posture and loss of skeletal muscle strength often found in the elderly contribute to reduction in the vital capacity and an increase in the residual volume of the lung. Table 35–6 outlines the pulmonary risk factors for the development of dyspnea in the elderly palliative care patient.

Respiratory muscle weakness may play a major role in some types of dyspnea. Palange and colleagues found that malnutrition significantly affected exercise tolerance in patients with COPD by producing diaphragmatic fatigue. In patients with cachexia, the maximal inspiratory pressure, an indicator of diaphragmatic strength, is severely impaired. Cachexia and asthenia occur in 80% to 90% of patients with advanced cancer, and are also prevalent in elderly patients with multiple comorbid psychiatric and medical conditions. These mechanisms may affect the development of dyspnea and fatigue in the elderly who have advanced nonmalignant and malignant disease. Ripamonti and Bruera have suggested that in some patients, dyspnea may be a clinical presentation of overwhelming cachexia and asthenia.

The multiple etiologies of dyspnea in the dying elderly patient include both malignant (e.g., tumor infiltration, superior vena cava syndrome, pleural effusion), treatment-related (Adriamycin-induced cardiomyopathy, radiation-induced pneumonitis, pulmonary fibrosis), and nonmalignant causes (e.g., metabolic, structural).

Two causes of dyspnea, deep vein thrombosis (DVT) and pulmonary embolism (PE), are prevalent in the elderly and are often unrecognized and undiagnosed. They may present as pleuritic chest pain with or without dyspnea and hemoptysis. The risk factors in the elderly include increased venous stasis in the legs, impaired fibrinolysis, coagulopathies, recent surgery, immobility, and congestive heart failure. Treatment is dependent on accurate diagnosis, and an estimate of risks versus benefits should be considered in deciding on a course of action. Ventilation-perfusion scans are the most reliable indicator of whether a PE has occurred, and the identification of a DVT as the source of the PE can be accomplished through noninvasive Doppler studies of the legs. Whether it is prudent or compassionate to perform these studies in the elderly patient who is dying should be considered. In the elderly patient who is not actively dying, diagnostic tests can be safely performed. Treatment with anticoagulants in addition to supportive symptom management will reduce the symptom burden and suffering.

### Treatment of Dyspnea

When possible, relief of dyspnea is aimed at treatment of the underlying disease process, whether malignant or nonmalignant in origin. Symptomatic interventions are used when the process is not reversible. Both pharmacological and nonpharmacological interventions should be employed. One patient may present with multiple etiologies; therefore, multiple interventions are indicated.

Therapeutic interventions are based on the etiology and include pharmacological (e.g., bronchodilators, steroids, diuretics, vasodilators, opioids, sedatives, antibiotics), procedural (e.g., thoracentesis, chest tube placement), nonpharmacological (e.g., relaxation, breathing exercises, music), radiation therapy, and oxygen. At the end of life, the pharmacological use of benzodiazepines, opioids, and corticosteroids

Elderly Patients

remain the primary treatment. Many palliative care professionals advocate the use of morphine to control dyspnea at the end of life.72–76 Often there is reluctance among staff to use opioids and sedatives in the elderly due to unfamiliarity with these medications, lack of experience in treating dyspnea in dying patients, low priority given to this symptom, or fear that these drugs may hasten death in the elderly. Table 35–7 outlines management guidelines based on presenting symptoms. Figure 35–1 reviews the overall assessment and management of dyspnea in the geriatric patient at the end of life.

CASE STUDY
An 80-Year-Old Woman with Metastatic Lung Cancer

An 80-year-old woman with metastatic lung cancer to bone, mediastinum, and lung has persistent dyspnea related to lymphangitic spread of disease. She has received radiation therapy to the mediastinum, and she completed a course of chemotherapy 2 months ago. She is still at home receiving morphine sulfate 30 mg orally every 4 hours, which has been very effective for bone pain. She tried long-acting morphine but did not like the way it made her feel. She is also receiving prednisone 30 mg orally 2 times daily for bronchospasm, and an albuterol inhaler, which she occasionally uses. Physical examination reveals breath sounds decreased bilaterally, occasional rhonchi, but no rales or crackles present. She has no distended neck veins, gallop, or peripheral edema. Her respiratory rate is 24 per minute at rest, and she complains of feeling breathless and anxious. She is also very fatigued and cannot sleep at night. She refuses to go to the hospital and says she wants to die in her own bed at home. She also is refusing further aggressive intervention and has signed a home DNR order.

Suggestions for Assessment and Intervention

What further symptom management can be offered to this patient?

1. Determine the etiology of the dyspnea in this patient. In the terminally ill patient, dyspnea is often due to multiple causes. A thorough history and physical examination should be performed and will assist in determining specific interventions. In this patient, the probable cause of the dyspnea is lymphangitic spread of the malignancy.

2. Excessive fatigue is present in this patient, and a complete blood count will determine if anemia is contributing to fatigue and dyspnea. Consider a trial

COPD, chronic obstructive pulmonary disease; DVT, deep venous thrombosis; PE, pulmonary embolism; WBC, white blood cell.
of a low-dose stimulant such as Ritalin 2.5–5 mg orally daily in the morning. This may decrease fatigue and give her more energy during the day.

3. Infection can be ruled out with a complete blood count. If pneumonia is suspected, try to arrange for a chest x-ray if the patient agrees or empirically initiate a trial of oral antibiotics. Although this patient has no signs of congestive heart failure on physical examination, it should be ruled out.

4. If available, use pulse oximetry to determine benefits of oxygen therapy or try nasal O₂ at 3 L/minute.

5. The patient is presently receiving morphine sulfate for pain. Increase her opioids by 25% to 50% to a dose of 40 to 45 mg orally every 4 hours to assist with tachypnea and anxiety.

6. Consider a trial with an anxiolytic such as ativan 0.5 mg orally every 8–12 hours.

7. Consider increasing the prednisone to treat the bronchospasm.

8. Encourage use of an albuterol inhaler 3 to 4 times a day for bronchospasm.

9. If oral morphine cannot be titrated to effect, consider a trial of nebulized morphine 2.5 to 5.0 mg every 4 hours, as needed, if available.

10. Consider the benefit versus burden of additional interventions that are employed. The patient has stated that no further interventions are to be used. Review the goals of care with the patient and family members.

11. Assess functional status and reduce the need for physical exertion. Provide for assistance with daily activities, positioning techniques, and frequent rest periods.

12. Address anxiety, provide support and reassurance. Determine level of support from family and friends, and spiritual and religious beliefs. Reassure patient that symptoms can be controlled.

13. Incorporate nonpharmacological interventions (e.g., progressive relaxation, guided imagery, and music therapy).

**Pain**

The physiological changes accompanying advanced age have been discussed in this chapter; however it is important to emphasize that the elderly are more sensitive to both the therapeutic and toxic effects of analgesics. The principles of drug selection, route of administration, and management of side effects are the same in the elderly population as for younger adults.

**Acetaminophen**

Acetaminophen is one of the safest analgesics for long-term use in the older population and should be used for mild to moderate pain. It is particularly useful in the management of musculoskeletal pain and is often used in combination with opioids. In older patients with normal renal and liver function, it can be
used safely and is highly effective for the treatment of osteoarthritis. In the setting of renal insufficiency, hepatic failure, or with patients who are drinking heavily or have a history of alcohol abuse, avoidance of acetaminophen is recommended.

**Nonsteroidal Antiinflammatory Drugs**

Nonsteroidal antiinflammatory drugs (NSAIDs) are useful as initial therapy for mild to moderate pain and can be used as an additive with opioids and nonopioids. In particular, NSAIDs are useful in the treatment of nociceptive pain related to bone or joint disease. When used concurrently with opioids, lower doses of opioids may be an additional benefit. NSAIDs are useful as initial therapy for mild to moderate pain and can be used as an additive with opioids and nonopioids. NSAIDs affect analgesia by reducing the biosynthesis of prostaglandins, thereby inhibiting the cascade of inflammatory events. They also have effects on pain receptors, nerve conduction, and may have central effects. The long-term use of traditional NSAIDs, aspirin and ibuprofen, are associated with gastrointestinal ulceration, renal dysfunction, and impaired platelet aggregation. The cyclooxygenase-2 (COX-2) enzymatic pathway is induced by tissue injury or by other inflammation-inducing conditions. There appears to be less risk of gastrointestinal bleeding with short-term use of the COX-2 selective NSAIDs. In particular, NSAIDs are useful in the treatment of nociceptive pain related to bone or joint disease. When used concurrently with opioids, lower doses of opioids may be an additional benefit.

---

**Figure 35-1.** Dyspnea management in the geriatric patient at the end of life.
Elderly patients with a history of ulcer disease are most vulnerable to the side effects of these drugs, which can cause renal insufficiency and nephrotoxicity. Cognitive dysfunction has been reported with the use of salicylates, indomethacin, naproxen, and ibuprofen. Also, NSAIDs are problematic in elderly patients with congestive heart failure, peripheral edema, or ascites. In the palliative setting, consideration of the risks versus the benefits to the elderly patient should be done. If, for example, the use of NSAIDs provides effective analgesia, and the life expectancy of the patient is limited (days to weeks), it is probably prudent to initiate this therapy.

Opioids

In older patients with moderate to severe pain who have limited prior treatment with opioids, it is best to begin with a short-half-life agonist (morphine, hydromorphone, oxycodone). Shorter-half-life opioids are generally easier to titrate than longer-half-life opioids such as levorphanol or methadone, and in the elderly may have fewer side effects. Recent research has demonstrated the importance of both liver biotransformation of metabolites and renal clearance of these metabolites. Most opioids are converted to substances that may have a higher potency than the parent compound or produce more adverse effects with repeated dosing and accumulation. Table 35–8 outlines the most commonly used opioids and their metabolites.

When prescribing opioids in the older population, it may be helpful to obtain baseline renal function studies. A normal serum creatinine does not indicate normal renal function; it is prudent to obtain a 24-hour creatinine clearance to accurately determine renal function.

Morphine is the most commonly prescribed opioid because of its cost and ease of administration. Morphine can be administered as an immediate-release tablet or a liquid formulation, in a controlled-release tablet administered every 8 to 12 hours (MS Contin), or every 24 hours (Avinza, Kadian). Plasma clearance of morphine decreases with age.97

When administering morphine for long-term use, the metabolites of morphine—morphine-3 and -6 glucuronide—may accumulate with repeated dosing, especially in the setting of impaired renal or hepatic function.86,88,89 If, after several days of treatment with morphine, the elderly patient develops side effects that include sedation, confusion, or respiratory depression, it may mean that there is an accumulation of these metabolites, and the opioid should be changed.

Hydromorphone (Dilaudid) is available in oral tablets, liquids, and parenteral formulations and will soon be available in a long-acting preparation. The main metabolite of hydromorphone (H3G) may lead to the same toxicity as seen with morphine—myoclonus, hyperalgesia, and seizures, especially in the setting of renal failure.90

Oxycodone is a synthetic opioid available in a long-acting formulation (OxyContin), as well as immediate-release tablets and a liquid preparation. In the oral formulation, it is one third to one half more potent than oral morphine. The cost of OxyContin may be prohibitive to some patients on limited incomes.

Fentanyl is a highly lipophilic soluble opioid, which can be administered spinally, transdermally, transmucosally, and intravenously. Transdermal fentanyl (Duragesic) is especially useful when patients cannot swallow, have difficulty adhering to an oral regimen, or have side effects to other opioids. There is some suggestion that transdermal fentanyl may produce less constipation when compared with long-acting morphine. Fever, cachexia, obesity, and ascites may have a significant effect on absorption, predictability of blood levels, and clinical effects.91,92 The fentanyl patch can be used safely in the older patient, but patients should be monitored carefully. It might be helpful when initiating therapy with the transdermal patch to begin with a short-acting opioid oxycodone 5 mg every 4 hours, to monitor the patient over 5 to 7 days. If this dose is tolerated, conversion to a fentanyl 25- mcg patch can be safely done. If, after initiation with the fentanyl patch, side effects develop, it is important to remember that they may persist for long periods (hours or even days) after the patch is removed. The frail elderly, however, who have experienced multiple side effects from opioids, may not do well with this route of administration. If this is the case, oral transmucosal fentanyl citrate (OTFC or Actiq) may be tried; it is composed of fentanyl on an applicator that patients massage or rub against the oral mucosa. Absorption occurs rapidly, and many patients begin to have relief after 5 to 10 minutes. This formulation is especially useful in settings where rapid onset of analgesia is needed, such as with severe breakthrough pain, or during a procedure or dressing change. This formulation is only to be used in opioid-tolerant patients who are already receiving an around-the-clock opioid to manage baseline pain. Adults should start with 200 mcg, and the dose should be titrated as needed.93

Methadone can be safely used in the older adult, provided they are carefully monitored. The half-life of methadone can be 2.4 to 72 hours and allows for prolonged dosing intervals. The long half-life increases the potential for drug accumulation and side effects before the development of steady state blood levels, thus placing the patient at risk for sedation and possible respiratory depression. Because of this possibility, close monitoring of these patients should be done during the first 7 to 10 days of treatment. When using high doses or when initiating the IV route, obtaining a baseline EKG is recommended because of the possibility of QT wave abnormalities.94 Methadone may bind as an antagonist to the NMDA receptor, which may be useful in the management of neuropathic pain.95 From a cost perspective, it is one of the less costly opioids, making it appealing to some patients on limited incomes.

As in younger individuals, the use of meperidine for the management of chronic cancer pain is not recommended. The active metabolite of meperidine is normeperidine, which is a proconvulsant. The half-life of normeperidine is 12 to 16 hours. With repeated dosing, accumulation of normeperidine can result in CNS excitability, with possible tremors, myoclonus, and seizures. Table 35–9 outlines guidelines for opioid use in the elderly patient.

Parenteral routes of administration should be considered in elderly patients who require rapid onset of analgesia, or require high doses of opioids that cannot be administered orally. They may be administered in a variety of ways, including the IV and subcutaneous route, using a patient-controlled analgesia (PCA) device. A careful evaluation of the skin in the elderly patient should be done before initiation of subcutaneous administration. If the patient has excessive edema, a low platelet count, or skin changes related to chronic steroid use, absorption may be impaired or subcutaneous tissue may not sustain repeated dosing, even with a permanent indwelling butterfly catheter. Infusion devices with the capability of patient-administered rescue dosing can be safely used in the elderly cancer patient. It is important to remember that severe cognitive impairment should not deter the use of IV administration, especially in the elderly patient at the end of life. Choice of analgesics and routes of administration must be based on individual assessment of each patient. Table 35–10 outlines indications for a subcutaneous or IV PCA pump.

Source: Adapted from McCaffery and Pasero (1999), reference 162.
A less aggressive approach may be necessary in elderly patients. Especially if the elderly patient is frail or has significant comorbidities, escalation should be performed. It is generally safe to begin with a dose 25% to 50% less than the dose for a younger adult, especially if the elderly patient is frail or has a history of side effects from prior opioid use. Generally, it is safe to titrate opioids 25% to 50% every 24 to 48 hours, although a less aggressive approach may be necessary in elderly patients.

**Dose Titration.** After initiation with an opioid, a stepwise escalation of the opioid dose should be done until adequate analgesia or intolerable side effects develop. The increased sensitivity of the elderly to opioid side effects suggests that careful titration and escalation should be performed. It is generally safe to begin with a dose 25% to 50% less than the dose for a younger adult, especially if the elderly patient is frail or has a history of side effects from prior opioid use. Generally, it is safe to titrate opioids 25% to 50% every 24 to 48 hours, although a less aggressive approach may be necessary in elderly patients.

**Case Study.**

**An 80-Year-Old Man with Bladder Cancer**

An 80-year-old man with bladder cancer and extensive intraabdominal and pelvic disease is receiving hydromorphone 6 mg orally every 4 hours and is reporting inadequate pain relief, with a pain intensity of 7/10. He also is having intermittent nausea and vomiting. He has been on this dose for about 6 weeks and is reporting having some confusion for the past week, which his wife has corroborated. He is also having periods of severe incidental pain related to movement. He has no “as needed” rescue doses ordered. For the past 2 weeks, he has been in bed most of the time. He also reports constipation, with no bowel movement for 5 days.

**Case Analysis.** What evaluation of this patient should be done and what changes in his opioid regimen should be made?

1. The etiology of the confusion should be determined. A careful review of all medications should be done, and all centrally acting medications discontinued. In this patient, his only additional medication is digoxin.
2. A digoxin level and appropriate laboratory data should be obtained to determine if he is digoxin toxic and if there is any metabolic etiology for his confusion. His digoxin level is normal, and his electrolytes and renal and liver function studies are normal.
3. A change in opioid is indicated, because this may be contributing to his confusion.
4. An evaluation for the etiology of the nausea and vomiting should be done. A history of onset, duration, temporal characteristics, and exacerbating/relieving factors should be obtained. A thorough physical examination is performed, with special attention to the abdominal and rectal examination. The physical examination reveals that bowel sounds are present, and the rectal exam reveals retained feces in the rectal vault.
5. An abdominal x-ray is done and shows extensive retained feces but no bowel obstruction. An abdominal CAT scan done 1 month previously revealed extensive intrapelvic and intraabdominal disease.
6. It has been determined that the etiology of the nausea and vomiting is related to severe constipation and may be worsened by intermittent extrinsic compression of the bowel by tumor infiltration.
7. The severe constipation may also be contributing to the development of confusion.
8. The decision is made to switch the patient to another opioid. In selecting another opioid, factors to consider include half-life, duration of action, and route of administration. The decision is made to start the patient on a continuous infusion of morphine until the nausea and vomiting resolve and then convert the patient to oral morphine. The equianalgesic dose table should be used as a guide. Because of the existence of incomplete cross-tolerance between drugs, advanced age, and cognitive changes, the alternative opioid should be reduced by 50% to 75%.
9. Disimpaction was attempted but could not be tolerated. A bowel regimen of an oil-retention enema followed by a Fleets enema was tolerated, and the patient had a large bowel movement. The patient was also started on an oral regimen of Senokot 2 tabs orally twice a day and Colace 300 mg orally daily.

**Management of Side Effects Related to Opioids.** The elderly with multiple medical conditions, who are frail and bedbound, are at greatest risk for potential side effects of opioids due to age-related alterations in pharmacokinetics, specifically distribution and elimination. Avoiding side effects by “starting low and going slow” is common advice given to many clinicians when treating elderly patients, but this advice may run the risk of undertreatment of pain. Careful monitoring and frequent assessment can prevent a minor side effect from becoming life-threatening in the elderly.
For mild nausea, vomiting, sedation, or confusion, it might be helpful to decrease the 24-hour total dose by 25% if the patient has adequate analgesia and is taking only a minimal number of “as needed” rescue doses in a 24-hour period. This strategy avoids a complete change in opioid, although anecdotaly, this approach may be useful for a limited time only; if the pain escalates, this will necessitate a titration of the opioid, and the side effects will return.

Nausea and vomiting are common with some opioids and are due to activation of the chemoreceptor trigger zone in the medulla, vestibular sensitivity, and delaying gastric emptying. If nausea and vomiting occur at the initiation of therapy, it is usually transient and self-limiting. Patients should be prescribed antiemetics on an as-needed basis. Nausea and vomiting should be aggressively treated in the older adult because of the dangers of dehydration and the need for hospitalization.

Treating the side effect can be effective but the risk of polypharmacy remains. If, for example, the elderly patient is experiencing sedation from the opioid, it may be wiser to decrease the 24-hour total dose rather than add a psychostimulant, which can produce irritability, tremors, anxiety, and insomnia. If decreasing the dose cannot be done, a small dose of a psychostimulant such as Ritalin 2.5 mg orally twice a day, or Provigil 100 mg orally twice a day can be effective in controlling daytime sedation. Changing the opioid can be another strategy to minimize or treat side effects. This intervention can be effective in the management of opioid-induced nausea and vomiting, especially if the patient has had limited exposure to opioids. Again, this strategy eliminates the use of an additional medication with its own potential side effects.

The addition of an adjuvant such as an NSAID has been shown to be effective in reducing the opioid requirement, thus allowing a reduction in the 24-hour opioid dose. Use of adjuvants will be discussed in the next section.

The elderly are particularly susceptible to opioid-induced constipation, and laxative and stool softener should be prescribed whenever an opioid is prescribed. Tolerance to the constipating effects of opioids does not occur, and patients need to be instructed regarding the ongoing need for laxatives and stool softeners. Constipation can be life-threatening in the debilitated elderly patient, especially if it is unrecognized and untreated. The initial presentation of opioid-induced constipation may be confusing. Abdominal signs and symptoms including pain, distension, and nausea may be absent, and the patient may present with confusion, depressed mood, and loss of appetite. Assessment of the elderly patient should include all medications including over-the-counter drugs—iron preparations, antacids, and drugs with anticholinergic properties. A bowel regimen should be routinely prescribed including senna stool softeners. Fluids should be encouraged, but maintaining adequate hydration may be difficult for some older patients. In addition, the intake of fluids may further worsen other symptoms, including peripheral edema, dyspnea, ascites, and other sites of third spacing.

Adjuvant Analgesics and Treatment

Several nonopioid medications have been found to be analgesic. These drugs alter, attenuate, or modulate pain perception. They may be used alone or in combination with opioids or nonopioid analgesics to treat many different pain syndromes, including neuropathic pain. Included in this category are antidepressants, anticonvulsants, N-methyl-D-aspartate (NMDA) antagonists, corticosteroids, and local anesthetics. All of these medications have side-effect profiles that can be especially harmful to the older patient, and careful monitoring is required.

Tricyclic antidepressants (TCAs) have been the most widely studied class of adjuvant medications for neuropathic pain. The action of these drugs is probably due to interruption of norepinephrine and serotonin-mediated mechanisms in the brain. Side effects, namely the anticholinergic side effects, often limit the use of these medications. Dry mouth, urinary retention, constipation, blurred vision, tachycardia and delirium are some of the more common side effects. Nortriptyline, a secondary amine, may be preferred in the older adult because it produces less orthostatic hypotension than amitriptyline, and desipramine may have lesser anticholinergic side effects than amitriptyline. TCAs are contraindicated in patients with coronary artery disease, narrow-angle glaucoma, and significant prostate hyperplasia. When initiating therapy, start the dose low, monitor patients, and titrate the dose in 10-mg increments every 7 to 10 days because tolerance to side effects develops.

Anticonvulsants are used to control sharp, shooting, burning, electric, and stabbing pain, typical sensations found in patients with neuropathic pain. Their analgesic effect is believed to be related to the slowing of peripheral nerve conduction in primary afferent fibers. Several different anticonvulsants are useful for neuropathic pain, including carbamazepine, gabapentin, phenytoin, and valproic acid. Carbamazepine should be used cautiously because of the side-effect profile—blood dyscrasias can occur. Gabapentin is thought to have several different mechanisms of action, including having NMDA antagonist activity. The most effective analgesic doses range from 900 mg to 3600 mg/day, in divided doses every 8 hours. Evidence supports the efficacy of gabapentin in several painful disorders, including diabetic neuropathy, postherpetic neuralgia, thalamic pain, spinal cord injury, and restless legs syndrome. The starting dose in elderly patients can begin as low as 100 mg a day, titrated by 100 mg a day every 3 days, until the onset of analgesia. The most commonly reported side effects of gabapentin are somnolence, dizziness, ataxia, tremor, and fatigue. Other anticonvulsants that have been used in the management of neuropathic pain include lamotrigine (Lamictal), topiramate (Topamax), zonisamide (Zonegran), and levetiracetam (Keppra), although no randomized controlled studies are available.

NMDA antagonists are believed to block the binding of excitatory amino acids, such as glutamate, in the spinal cord. Medications that inhibit this receptor interfere with the transmission of pain across the synaptic area. Methadone, ketamine,
and dextromethorphan are all NMDA antagonists thought to have analgesic effects in the management of neuropathic pain.\textsuperscript{108,109} Ketamine should be used with caution because of its psychomimetic effects, and routine use is not recommended. At the end of life, it has been used in the management of refractory neuropathic pain.\textsuperscript{110}

Corticosteroids have specific and nonspecific effects in managing pain, including treatment of painful nerve or spinal cord compression, reducing tissue edema and inflammation, and by lysis of some tumors. The mechanism of effect is by inhibition of prostaglandin synthesis and decreasing edema surrounding neural tissues.\textsuperscript{111} Corticosteroids are the standard treatment for malignant spinal cord compression (dexamethasone 16 to 96 mg/day). They may be useful in the management of painful malignant lesions involving the brachial or lumbosacral plexus, hepatic enlargement, distension, and pain.\textsuperscript{112,113} Corticosteroids are also helpful in the management of bone pain as well as in the treatment of bowel obstruction.\textsuperscript{114,115} Corticosteroids may also be useful in the management of nausea and vomiting. In the older adult, corticosteroids should not be used concurrently with NSAIDs due to the potential increased risk of bleeding.

Local anesthetics have been shown to relieve pain when administered orally, topically, intravenously, and intraspinally. Mexiletine has been useful when anticonvulsants have failed.\textsuperscript{116} Topical local anesthetic gels and topical Lidoderm patches have been useful in the management of postherpetic neuralgia\textsuperscript{117} and other neuropathic pain syndromes, including peripheral neuropathy, postthoracotomy pain, stump neuritis, complex regional pain syndrome, radiculopathy, and postmastectomy pain.\textsuperscript{118} Lidoderm patches 5% should be applied 24 hours on/12 hours off, within a 24-hour period. They have an excellent safety profile; systemically active serum levels of lidocaine do not occur, and patients can cut the patches to fit small areas. In many older patients, the patches may provide an opioid-sparing effect—the patient may use less opioid analgesia within a 24-hour period. IV lidocaine boluses at doses of 1 to 5 mg/kg, maximum 500 mg, administered over 1 hour, followed by a continuous infusion of 1 to 2 mg/kg/hr has been reported to reduce intractable neuropathic pain in the palliative care and hospice setting.\textsuperscript{119}

Bisphosphonates inhibit osteoclast–mediated bone resorption and alleviate pain from metastatic bone disease and multiple myeloma.\textsuperscript{120,121} Analgesic effects can occur in 2 to 4 weeks, and for this reason, might not be suitable for patients at the end of life. Pamidronate disodium and zoledronic acid are used in patients with metastatic lesions from breast and prostate cancer. Pamidronate sodium has been shown to reduce pathological fractures in patients with breast cancer.\textsuperscript{122} Patients should be monitored with serum calcium levels because hypocalcemia can occur.

Calcitonin may be given subcutaneously or intranasally to relieve pain associated with osteoporotic fractures.\textsuperscript{123} Usual doses are 100 to 200 IU/day and are usually well tolerated. At the end of life, this is probably not a practical or helpful intervention.

Radiation therapy is extremely helpful in relieving painful bone lesions. In many instances, single-fraction external beam therapy can be used. Onset of relief can be fairly rapid, often within days of treatment and may be a helpful intervention when patients are having side effects to opioid therapy. Unless a single fraction is considered, at the end of life it is not a practical intervention.

Radionuclide therapy is often helpful when there is widespread bony metastatic disease that cannot be easily targeted with localized radiotherapy.\textsuperscript{124} Strontium (Metastron) is a radiopharmaceutical calcium analogue taken up by the skeleton into active sites of bone remodeling and metastasis. A large clinical trial demonstrated that strontium was an effective adjuvant to local radiotherapy, and that it reduced disease progression, decreased new sites of pain, and decreased systemic use.\textsuperscript{124} The latency of response can be as long as 2 to 3 weeks, and patients should continue their opioid therapy. Because of this delayed onset of analgesia, patients who are actively dying are not candidates. Side effects associated with strontium use include thrombocytopenia and leucopenia. Samarium lexidronam (Quadramet) is a radiopharmaceutical that has an affinity for bone, and concentrates in areas of bone turnover with hydroxyapatite, which is useful for metastatic bone pain. Patients should also be instructed that a transitory pain flare can occur, and analgesics may need to be titrated.

Invasive Approaches

Anesthetic and neurosurgical approaches are indicated when conservative measures using opioids and adjuvant analgesics have failed to provide adequate analgesia, or when the patient is experiencing intolerable side effects. The use of these approaches is not contraindicated in the older adult. The clearest indication for these approaches is intolerable side effects. These procedures include regional analgesia (spinal, intraventricular, and intrapleural opioids), sympathetic blockade and neurolytic procedures (celiac plexus block, lumbar sympathetic block, cervicothoracic [stellate] ganglion block), or pathway ablation procedure (chemical or surgical rhizotomy, or cordotomy). At the end of life, these approaches may be useful in some older patients who have intractable pain that cannot be managed with systemic treatment.

Nonpharmacological Approaches: Complementary Therapies

Physical and psychological interventions can be used as an adjunct with drugs and surgical approaches to manage pain in the older adult. These approaches carry few side effects and, when possible, should be tried along with other approaches. In selecting an approach in the dying patient, factors that should be considered include physical and psychological burden to the patient, efficacy, and practicality. If the patient has weeks to live, these strategies may allow for a reduction in systemic opioids and diminish adverse effects.
Cognitive-behavioral interventions include relaxation, guided imagery, distraction, and music therapy. The major advantages of these techniques are that they are easy to learn, safe, and readily accepted by patients. Cognitive and behavioral interventions are helpful to reduce emotional distress, improve coping, and offer the patient and family a sense of control. Other physical interventions such as reflexology and massage therapy have been shown to relieve pain and produce relaxation.125,126

The Cognitively Impaired Elderly: Problems in Assessment and Fear of Treating Pain and Other Symptoms

Cognitively impaired nursing home residents present a special barrier to pain assessment and management.127–131 Residents of nursing homes exhibit very high rates of cognitive impairment.132 Most studies of nursing home residents reveal that cognitively impaired nursing home residents are prescribed and administered significantly less analgesic medication, both in number and in dosage of pain drugs, than their more cognitively intact peers.132,133

Assessment of pain in cognitively impaired elderly at the end of life remains a special challenge. Mild to moderate cognitive impairments seem to be associated with a decrease in propensity to report pain.132 In severely cognitively impaired individuals, assessment is often difficult because these individuals frequently cannot verbalize their reports of pain. Ferrell and colleagues134 found in their evaluation of 217 elderly patients with significant cognitive impairment that 83% could complete at least one pain scale, with the McGill Present Pain Intensity Scale having the highest completion rate, and 32% were able to complete all of the scales presented.

The best way to assess pain is to ask the individual. In the cognitively impaired elderly, it is difficult to assess pain. The ability of caregivers, either family or staff, to assess pain in this population is crucial. In one study of caregiver perceptions of nonverbal patients with cerebral palsy, more than 80% of the caregivers used aspects of crying and moaning to alert them to nonverbal patients with cerebral palsy, more than 80% of the caregivers used aspects of crying and moaning to alert them to the patient and family a sense of control. Other physical interventions such as reflexology and massage therapy have been shown to relieve pain and produce relaxation.125,126

Delirium at the End of Life

Prevalence. Delirium is a frequently occurring consequence of advanced cancer and is characterized by disturbances in arousal, perception, cognition, and psychomotor behavior.136,137 In all settings, delirium is a common symptom in the elderly medically ill and cancer patient. The presence of delirium contributes significantly to increased morbidity and mortality. Estimates of the prevalence of delirium range from 25% to 40% in cancer patients at some point during their disease, and in the terminal phases of disease, the incidence increases to 85%.139,136–138 In elderly hospitalized patients, delirium prevalence ranges from 10% to 40%, and up to 80% at the end of life. One of the major problems in the treatment of delirium in the elderly patient is lack of assessment by hospital staff, especially if the patient is quiet and noncommunicative.

Predisposing and Etiological Factors. The etiology of delirium in the medically compromised and dying elderly patient is often multifactorial and may be nonspecific. In an elderly patient, delirium is often a presenting feature of an acute physical illness or exacerbation of a chronic one, or of intoxication with even therapeutic doses of commonly used drugs.139 A number of factors appear to make the elderly more susceptible to the development of delirium (Table 35–11).

Delirium can be due to the direct effects of the disease on the CNS, metabolic reasons including organ failure, electrolyte imbalance, infection, hematological disorders, nutritional deficiencies, paraneoplastic disorders, hypoxemia, chemotherapeutic agents, immunotherapy, vascular disorders, hypothermia, hyperthermia, uncontrolled pain, sensory deprivation, sleep deprivation, medications, alcohol or drug withdrawal, diarrhea, constipation, or urinary retention. A variety of drugs can produce delirium in the medically ill or elderly patient (Table 35–12). In the palliative care setting, multiple medications are generally required to control symptoms at the end of life. In patients with advanced cancer, prospective data suggest a prevalence of delirium in 28% to 42% on admission to a palliative care unit.140 Given the projected increase in the numbers of elderly patients, health care providers will encounter the need for management of delirium in the elderly more frequently.

Other risk factors for the development of delirium include advanced age, cancer, preexisting cognitive impairment, hip fractures, and severe illness.141–143 In cancer patients, risk factors that have been identified include advanced age, cognitive impairment, low albumin level, bone metastases, and the presence of hematological malignancy. In one study that determined risk factors for delirium in oncology patients, specific etiological factors in the elderly were identified and include reduced cholinergic reserves of the brain, high prevalence of cognitive impairment and comorbid disease, visual and hearing loss, and impaired metabolism of drugs.144,145

The diagnosis of delirium in an elderly patient carries with it serious risks. Delirium produces distress for patients, families, and health care providers. Depending on the severity of symptoms (fluctuating cognitive changes, hallucinations, agitation, or emotional lability), patients often require one-to-one observation, chemical, and, rarely, physical restraints. Falls and pressure ulcers are associated with the hyperactive and hypoactive subtypes.146
Given the projected increase in the numbers of elderly patients, health care providers will encounter management of delirium in the elderly more frequently. To reduce the risk of polypharmacologically induced delirium, it is prudent to add one medication at a time, evaluating its response, before adding another medication.

Delirium in the elderly patient is often undertreated for several reasons, including lack of assessment tools, inadequate knowledge of early signs of confusion, and inadequate time spent with the patient to determine cognitive function—all factors that lead to underdiagnosis. In addition, behavioral manifestations of delirium may include a variety of symptoms that may be interpreted as depression, or dementia.

A multifactorial model of delirium in the elderly, with baseline predisposing factors and the addition of various insults, has been established by Inouye.141 The factors that have been identified to be contributory to baseline vulnerability in the elderly include visual impairment, cognitive impairment, severe illness, and an elevated blood urea nitrogen/creatinine ratio of 18 or greater. Other factors that have been identified in the elderly include advanced age, depression, electrolyte imbalance, poor functional status, immobility, Foley catheter, malnutrition, dehydration, alcohol, and medications, including neuroleptics, opioids, and anticholinergic drugs. Lastly, delirium in an elderly patient is often a precursor to death and should be viewed as a grave prognostic sign.147

Alcohol withdrawal may be the cause of delirium in the elderly. In one study, organic mental syndromes were diagnosed in more than 40% of elderly alcoholics admitted for alcohol abuse, and delirium was found in about 10% of these.148 Illness, malnutrition, concurrent use of a hepatotoxic drug, or one that is metabolized by the liver may result in increased sensitivity of the elderly to alcohol. Alcohol, combined with other medications, especially centrally acting medications, can produce delirium in the elderly.

The diagnosis of delirium in an elderly patient carries with it serious risks. An agitated delirious patient may climb out of bed; pull out Foley catheters, IV lines, and sutures; and injure staff in an attempt to protect himself from perceived threat. Mental status questionnaires are relatively easy to administer, and an examination should be performed on all patients with mental status changes. The Mini-Mental State Exam, a 10-item test, is easy to administer to an elderly patient.149

Delirium and Dementia

Delirium may often be superimposed upon dementia in the elderly patient. In clinical practice, it is important to distinguish whether the delirious patient has an underlying dementia. When an elderly demented patient becomes delirious, it should be assumed that an organic precipitating factor—metabolic, drug-induced, acute illness—is the cause, and the patient should be evaluated for the etiology and treated. The distinction is not always apparent. Both delirium and dementia feature global impairment in cognition. Obtaining a careful history from family members or caregivers to learn about the onset of symptoms is probably the most important factor in making the distinction. In general, acute onset of cognitive and attentional deficits and abnormalities, whose severity fluctuates during the day and tends to increase at night, is typical of a delirium. Delirium, in general, is a transient disorder that seldom lasts for more than a month, while dementia is a clinical state that lasts for months or years.\textsuperscript{139} Dementia implies impairment in short- or long-term memory associated with impaired thinking and judgment, with other disturbances of higher cortical function, or with personality change.\textsuperscript{130} The presence and severity of cognitive deficits and attentional disturbances should be further established by a comprehensive mental status examination.

Treatment of Delirium

Treatment of delirium includes an identification of the underlying cause, correction of the precipitating factors, and symptom

management of the delirium. In the very ill or dying patient, however, the etiology may be multifactorial, and the cause is often irreversible.

If delirium is occurring in the dying elderly patient and the goal of care has been identified as the promotion of comfort and relief of suffering, diagnostic evaluations (imaging and laboratory studies) would not prove beneficial. Interventions that may be helpful include restoration of fluid and electrolyte balance, environmental changes, and supportive techniques such as elimination of unnecessary stimuli, provision of a safe environment, and measures that reduce anxiety. In many cases, the etiology of delirium may be pharmacological, especially in the elderly patient. All nonessential and CNS-depressant drugs should be stopped. Figure 35–2

![Diagram of Delirium Management]

reviews the overall assessment and management of delirium in the geriatric patient at the end of life.

Pharmacological treatment includes the use of sedatives and neuroleptics. Breitbart and Jacobsen have demonstrated that the use of lorazepam alone in controlling symptoms of delirium was ineffective and contributed to worsening cognition. This approach was ineffective and contributed to worsening cognition. These authors advocate the use of a neuroleptic such as haloperidol, along with a benzodiazepine, in the control of an agitated delirium. Other neuroleptics, risperidone and olanzapine, have also been used to treat delirium in the elderly, and may have fewer side effects. The oral route is preferred, although in cases of severe agitation and delirium, the parenteral route should be used. In one study by Breitbart, 79 cancer patients were treated for delirium with olanzapine and age over 70 years was found to be the most powerful predictor of poorer response to olanzapine treatment. Other factors included history of dementia, CNS changes that normally occur with aging and the impact of progressive disease on an already frail system. Management of symptoms at the end of life in the elderly patient is different from the younger age group because of their altered response to medications, their fear of taking medication, and the need to involve and educate informal and formal caregivers, who are often elderly themselves. Pain, respiratory distress, and delirium are the three most common symptoms in the elderly patient who is dying. Relief of these symptoms is a basic priority for care of the dying elderly patient. Continued assessment of the patient will allow for drug changes, dose adjustments, and relief of distressing symptoms. Providing relief from these symptoms will help facilitate a peaceful death, one that is remembered as such by family and friends.

**Summary**

Elderly patients who are dying should be able to receive skillful and expert palliative care. This means that caregivers must become knowledgeable about the aging process—the physiologic changes that normally occur with aging and the impact of progressive disease on an already frail system. Management of symptoms at the end of life in the elderly patient is different from the younger age group because of their altered response to medications, their fear of taking medication, and the need to involve and educate informal and formal caregivers, who are often elderly themselves.

Pain, respiratory distress, and delirium are the three most common symptoms in the elderly patient who is dying. Relief of these symptoms is a basic priority for care of the dying elderly patient. Continued assessment of the patient will allow for drug changes, dose adjustments, and relief of distressing symptoms. Providing relief from these symptoms will help facilitate a peaceful death, one that is remembered as such by family and friends.

Poor, Homeless, and Underserved Populations

Last year at this time I was locked up in a psych ward because I’d tried to kill myself and today I’m fighting for my life. Isn’t that ironic?—Matt, a 58-year-old man recently diagnosed with stage IV squamous cell cancer of the hypopharynx, who just completed chemotherapy and radiation therapy after surgery, and refused hospice referral

Poor people are at risk for a bad death.

People whose lives have been filled with physical and emotional deprivation may be suspicious of attempts to engage them in “shared” decision-making to limit therapy, regardless of its likely benefits or burdens.

Some poor people have comorbidities (e.g., mental illness, substance abuse, and other chronic diseases) and other social characteristics that have marginalized them in society.

Poor people’s interactions with the health care system are frequently marked by rejection, shame, and lack of continuity of care.

Poverty is inextricably linked to increased morbidity, premature mortality, and limited access to both preventive health care and ongoing medical care. Beyond the medical outcomes of poverty, the individual and community costs are substantial and often invisible. People who are poor constitute a vulnerable population, a term used in community health to describe social groups at greater risk for adverse health outcomes. The root causes of this vulnerability typically are low socioeconomic status and a lack of access to resources.1 The Institute of Medicine’s report, which evaluated racial and ethnic disparities in health care, failed to address the role of poverty in disparities.2 However, the role of poverty in contributing to inequalities, independent of race and ethnicity, is difficult to decipher because class and race are often closely intertwined.3,4 Some believe poverty may be most responsible for disparities in health care.4

While much has been written about end-of-life care in the United States,5–8 with some recent exceptions, little has been said about those in our society who live at its margins, such as the urban poor.9–12a To be poor and to have a progressive, life-threatening illness presents more challenges than either one of these conditions alone. As Taipale elegantly notes, “Poverty means the opportunities and choices most basic to human development are denied [p. 54].”13 Consider the following questions: What type of death would a person hope for who doesn’t have a home or lives in a room without a phone or a toilet or a kitchen? What are the meanings of life-threatening illness and death when premature death is an all-too-common part of life? What matters at the end of life if most of your life has been spent trying to survive day to day? All of these questions, in part, introduce us to the worlds of the poor who are confronting a life-threatening illness. Physical, psychological, and spiritual deprivation isn’t all that poor people contend with—deprivation also harms the moral self and the ability both to act and to live autonomously.14

The purpose of this chapter is to examine the characteristics of the poor as an underserved population that place them
at particular risk when palliative care is needed. In particular, this chapter looks at a subset of the poor who are homeless or marginally housed, and how this affects both access to and quality of care at the end of life. The experience of being poor is not a single experience, as poor persons are as diverse a population as the nonpoor. The discussion in this chapter focuses on inner-city or urban poor, who are often marginally housed or homeless. Case studies are used to illustrate the concepts discussed and to demonstrate the need for more research to guide practice. The cases described are composite and reflective of the author’s practice in a metropolitan-area public health system that is greatly impacted by HIV/AIDS and by homelessness. As a result, these cases are not generalizable to all the poor or even to all the homeless. Being poor is only one of several characteristics that affect health status and limit access to resources. Persons with many vulnerabilities (e.g., being poor AND a member of a minority community, elderly, or having other medical problems) are at the greatest risk for adverse outcomes at the end of life.15

**Epidemiology of Poverty in the United States**

More than 34 million Americans are poor. The poverty line established by the federal government is based on annual income. In 2002, a single adult was considered poor if his or her income was less than $9,359, and a family of four (with 3 children under 18 years) was considered poor if their annual income was less than $18,307.16 Thirty-four million Americans represent just over 12% of the entire population of the United States. Table 36–1 lists states whose poverty level exceeds the national average. Many poverty experts, however, believe the federal definition of poverty underestimates the true prevalence of poverty in the United States. For example, the poverty line (annual income) does not capture cost-of-living differences across the country or out-of-pocket medical costs.

The faces of the poor in the United States disproportionately include persons of color, children, and female-headed families.16 African Americans have the highest rates of poverty in the United States (24.1%), followed by Hispanics (21.8%), Asian/Pacific Islanders (10.3%), and whites (8.0%) according to the U.S. Census Bureau Report for 2002.16 Children have greater rates of poverty than young and middle-aged adults and the elderly. Almost 50% of the families living in poverty in the United States are headed by a woman.16

While poverty is not confined to urban areas, as evident in Table 36–1, 78% of the poor live in or near the more populous metropolitan areas, and 40% of all the poor live in inner (or central) cities.16 Most of the poor have access to some type of housing or shelter, even if the basic accommodations (telephone, cooking and refrigeration, heat, water, private toilet, and bathing facilities) are inadequate. However, for a small subset, housing is marginal or unavailable. This subset is the focus of the following discussion.

**Definition and Prevalence of Homelessness**

Homelessness is defined in the Stewart McKinney Homeless Act as a condition under which persons “lack fixed, regular and adequate night-time residence” or reside in temporary housing such as shelters and welfare hotels.17 Calculating the number of Americans homeless or marginally housed is extremely difficult. Most cross-sectional studies fail to capture persons transiently homeless, the hidden homeless staying with family members, those living in cars or encampments, and others living in single-room occupancy hotels (SROs), sometimes known as welfare hotels. Additionally many of the poor and, in particular, the homeless, avoid contact with social and health services.

According to the National Coalition for the Homeless, every night between 400,000 to 800,000 Americans are homeless; 3.5 million Americans experience homelessness in a given year.14 Persons who are homeless are not members of a homogenous group. Some are street people and chronically homeless, while others are homeless because of a financial crisis that put them out of stable housing. Street people may be more reluctant to accept services and may have much higher rates of concurrent substance abuse and mental illness, that is, the so-called dual diagnosed.15 Homeless persons frequently are also persons of color, veterans, victims of domestic violence, the mentally ill, and substance abusers.20 While the rates of
mental illness and substance abuse are higher in the homeless than persons who are stably housed, assuming that all the poor, or, for that matter, all homeless suffer from these problems leads only to stereotypes. Domestic violence, mental illness, and substance abuse are not confined to the poor; hence, poverty does not cause these problems, although it may exacerbate them.

Health Problems Associated with Homelessness and Poverty

A number of health problems are associated with homelessness. Many of these problems are related to environmental factors such as exposure to weather conditions, poorly ventilated spaces, unsafe hotels and street conditions, and high-crime neighborhoods, where the poor tend to live. These health problems (Table 36–2) include malnutrition, lack of access to shelter and bathing facilities, problems related to drug and alcohol use, chronic mental illness, and violence-related injuries. One fifth of the homeless have a major psychiatric illness. About one in three homeless persons abuse drugs and alcohol. Drugs and alcohol are sometimes used to self-medicate distressing psychiatric symptoms (e.g., anxiety, depression).

A recent meta-analysis of the influence of income inequality and population health concluded that although the direct effects of poverty on population health were not evident, the individual effects of poverty on health status are irrefutable. Consider the case of coronary artery disease (CAD): the link between onset of CAD and low socioeconomic status (SES) has been established and is believed to be related to lifestyle factors, such as dietary habits, smoking, and physical activity. Recent research suggests that poor cardiac outcomes among the poor may also be related to limited access to standard medical care. Persons who are poor, on average, have shorter life expectancies than those whose incomes are higher. Men in Harlem have life expectancy rates comparable to those living in developing countries, such as Bangladesh.

Poverty, Life-Threatening Illness, and Quality of Life

Poor people endure a heavier burden of cancer according to a report from the American Cancer Society. The key findings of the impact of poverty on cancer care, irrespective of race and ethnicity, are listed in Table 36–3. In general, poor people encounter substantial barriers to obtaining quality cancer care, experience more pain and suffering, and are more fatalistic about cancer.

Understanding the role race and ethnicity play in the end-of-life experience of the urban poor is complex. Nevertheless, three studies examined the impact of economic resources on quality of life for persons with life-threatening illnesses. Being poor (defined as having an annual income of less than $20,000) negatively affected the quality of life reported by mostly white (85%) men newly diagnosed with prostate cancer, though low income was not related to quality of life over time. However, the lack of health insurance did predict worse quality of life for men with prostate cancer over time but not at baseline. In a qualitative study of heterosexual couples in which only one partner was HIV-positive, the investigators were surprised to learn the “benefits” of having AIDS in providing poor persons with access to subsidized housing, food, and other social services. Indeed, these researchers noted that, given policy changes in welfare programs, having an AIDS diagnosis was a commodity that brought with it benefits

Table 36–3

Poverty and Cancer: Findings from an American Cancer Society Report

- Poor people lacking access to quality health care are more likely to die of cancer than nonpoor.
- Poor people experience greater cancer-related pain and suffering.
- Poor people facing significant barriers to getting health insurance often do not seek necessary care if they are unable to pay for it.
- Poor people and their families make extraordinary sacrifices to obtain and pay for care.
- Cancer education and outreach efforts are insensitive and irrelevant to the lives of many poor people.
- Fatalism about cancer is common among the poor and often prevents them from accessing care.

Source: Adapted from Freeman (2004), reference 4.
that the poor were otherwise ineligible to receive. In other words, for poor people, having AIDS improved their quality of life. In a cross-sectional study of 212 adults with heart failure who were predominantly female (68%) and black (53%), quality of life was not related to physiological measures of heart function, but was correlated with greater income, social support, and positive health beliefs. Economic resources were associated with improved quality of life.

In his recently published book, Dancing with Broken Bones: Portraits of Death and Dying Among Inner City Poor, Moller poignantly recounts the stories of poor patients followed by an oncology clinic in a midwest city. His insights about the suffering of the urban poor are exquisite: “. . . the dying poor are the quintessential violators of the American dream; they live in the shame of poverty and with the unpleasantness of dying [p. 10].” Since much of a person’s “worth” in American society is connected with social status indicators such as occupation and income, the poor represent those who haven’t made it. Being poor becomes a matter of personal failure rather than a social problem. From Moller’s longitudinal qualitative study of poor inner-city patients, their families, and their health care providers, the researcher drew a number of conclusions that are listed in Table 36–4. His work can perhaps be summed up by saying that the indignities of being poor in America are only intensified when that person is also dying. Unlike persons who are not poor, dying is not always feared in the same way, as it may represent freedom from the misery of living.

### Table 36–4

**Insights About the Dying Poor**

- Poverty inflicts substantial harm throughout life.
- Poverty exacerbates indignity and suffering throughout dying.
- Patients/families are often mistrustful and angry about the care received.
- Patients, at the same time, are often grateful for the care received.
- Spirituality plays an important role in providing strength and resilience when dying.
- Social isolation increases suffering.
- Hidden and sometimes unexpected sources of support can emerge from family and community.
- The emergency room is the front door to health care.
- The organization of medical care is frequently fragmented and lacks continuity.
- Funerals are important rituals, and their cost creates enormous stress for survivors.

**Clinical Presentations of Advanced Disease in the Poor**

Persons who are poor frequently present with advanced disease. In addition to the late-stage disease presentation, many have significant comorbidities that affect both the palliation of symptoms and the course and treatment of underlying illnesses. These clinical management issues usually occur within the context of complex psychosocial situations, as the following case illustrates:

#### Case Study

**Lana, a Patient with AIDS**

Lana, a 43-year-old white woman, has been living in a shelter since her boyfriend died 18 months ago. She was diagnosed with AIDS 4 years ago after a hospitalization for *Pneumocystis carinii* pneumonia. Lana was shocked and ashamed by this diagnosis because she didn’t suspect she was HIV positive. Since that time, she has had repeated hospitalizations, including several for delirium secondary to crack and alcohol use. Currently Lana is taking four antiretroviral medications through a directly observed therapy program (DOT) arranged by her case manager. In addition to AIDS and alcohol and crack abuse, her medical problems include seizure disorder, depression, liver disease, hepatitis B and C infections, and chronic pain from a motor vehicle accident, which fractured her cervical spine and required a metal plate to stabilize the fracture. Lana has lost touch with her family; she is one of 8 children who grew up in the Midwest. Her father was an alcoholic; both of her parents died years ago. Lana had a daughter when she was 15 years old but hasn’t seen her daughter in 14 years, when Lana was put in jail for drug use. She doesn’t know where her daughter is living. None of her family members know about Lana’s lifestyle or about her AIDS diagnosis, and she is adamant that they not be told.

Comorbidities, especially those related to drug use, complicate symptom management and other medical management. As Lana’s case study points out, there were several competing factors that may influence her providers’ willingness to aggressively manage her pain. Persons known to be chemically dependent are often denied treatment for pain because of providers’ concerns of aberrant or drug-hoarding behaviors. Will Lana take the medication as ordered? Is she likely to sell her opioids for cocaine? Are her medications safe in the shelter? Does she have a place to keep them or are others likely to steal them? Some providers even question the use of opioids for any non-malignant pain syndrome. Who will prescribe opioid medications? If Lana is seen in a teaching clinic, will she need to negotiate the need for analgesia with each new doctor that rotates through? Does she have money or insurance to pay for
the medications? Is there a pharmacy near the shelter that carries them? According to a study by Morrison and colleagues,31 pharmacies in predominantly nonwhite neighborhoods in New York City were less likely to carry opioids for pain management than were pharmacies in neighborhood serving predominantly white communities. Most shelters are located in inner cities, not in middle class or affluent communities, where more whites live. Poor social conditions, criminal activity, and the threat of violence are significant barriers to effective pain management for persons with life-threatening illnesses.12 Lana is receiving DOT antiretroviral therapy, and, therefore, she is being followed carefully. Perhaps this support system could be enlisted to oversee her pain management and her overall safety and well-being.

Access to treatment is a significant factor that influences symptom management for this population. For example, if an antiemetic prescribed to relieve the chronic nausea experienced by a poor person with pancreatic cancer is not covered on the Medicaid formulary, or the person is not eligible for any drug-assistance program, the range of medications used to manage the nausea will be severely limited. Additionally, use of high-tech methods to control symptoms are probably not an option for the person who lives in a tent encampment. Most poor persons are institutionalized to manage uncontrolled symptoms and terminal care that cannot be managed sufficiently on the street or in the shelter.10

The management of symptoms associated with progressive illness is further complicated by end-organ diseases, such as liver or renal disease, that may alter the pharmacokinetics of medications used to palliate symptoms. Clinically significant drug–drug and drug–nutrient interactions are common with antiretrovirals that Lana is taking. Determining whether a patient is experiencing an adverse drug reaction is not easy when the person has comorbidities, has rapidly progressive disease, is malnourished, or may be continuing to use alcohol or other substances.

Comorbidities also affect the healthcare providers’ ability to realistically estimate prognosis and the nature of symptoms or problems that might occur down the road. Charting the dying trajectory for the chronic progressive illness may be conceivable, but superimposing the acute illnesses and injuries that the very poor live with and manage creates jagged peaks and valleys in a downward course. How quickly the life-threatening illness will progress becomes a prognostication puzzle; some persons living on the street truly seem to have had nine lives. In addition to HIV disease, Lana’s liver disease may limit her survival. If she resumes using drugs and alcohol, her addiction could also hasten her death.

There is another issue to consider with Lana—adherence to treatment. Despite the prevalence of substance abuse among the poor, lack of attention to self-care activities cannot be assumed in all drug users. Some homeless persons who use drugs manage complex HIV antiretroviral regimens that require scrupulous attention to when to eat, which other medications may or may not be taken at the same time, and the necessary several-times-a-day dosing.32 Race, class, and housing status cannot be used as surrogate predictors of who abuses drugs and alcohol or who will adhere or not adhere to treatment demands.

**Psychosocial Factors Influencing Palliative Care Available to the Poor and Homeless**

Health care professionals committed to supporting patients’ right to a “good death” may be challenged when working with the poor and the homeless. The good death is described as: (1) free from avoidable distress and suffering, (2) in accord with the patient and family’s wishes, and (3) consistent with clinical, cultural, and ethical standards.7 Bad deaths, in contrast, are accompanied by neglect, violence, or unwanted and senseless medical interventions.7 Persons who are poor or homeless are at risk for bad deaths. Many persons have had episodic contact with the health care system during acute illnesses or life-threatening trauma and may wind up receiving life-saving therapies such as mechanical ventilation, vasopressors, dialysis, and other therapies. All too often, the client does not have an advance directive or a surrogate decision-maker to articulate his or her wishes. Furthermore, in the absence of a competent patient or family directing otherwise, the technological imperative of hospitals and physicians in training may see saving a life at any cost of greater value.5 Nevertheless, what constitutes a good or bad death is a question that can only be answered by the individual person and cannot be predicted based on group membership or economic resources.5

Basic survival needs (food, shelter, clothing, protection) are of primary concern to the poor, often of greater and more pressing importance than the existential crisis of facing one’s own mortality. Seeing others die prematurely, often under violent or disturbing circumstances, may be an all-too-common experience for this population.34 Table 36–5 lists challenges to providing a good death in this population. The lack of resources, both economic and human, limit the palliative options available to the person who is poor. In the movie The Wizard of Oz, Dorothy’s refrain, “There’s no place like home, there’s no place like home,” speaks of an almost faraway magical experience that many who are poor and dying cannot even imagine. Housing is so essential to health that, for those of us who do not worry about having a roof over our heads at night, its importance is taken for granted. Many persons who are poor and don’t have enough to get by are often trying to figure out how to find a place to stay. And for those with a place, the concerns may be keeping the utilities (lights, heat, water) on and having enough money for other needs.

In addition to basic survival needs of the poor that influence their end-of-life experiences are their relationships with the healthcare professionals who take care of them. Health care professionals can and often do stigmatize patients for their appearance or lack of hygiene. Sometimes the presence of
body odor leads to rejection. Historical events and power differential in patient-provider roles can also affect such relationships. For example, the African-American experience with the medical care system includes the Tuskegee experiment and other instances of abuse. Many African Americans feel betrayed by the predominantly white medical care system and believe their trust in the system has been violated.35

Many of the poor receive care in public health care systems or indigent care settings that often serve as teaching hospitals, and where continuity of care is an illusion.10 Additionally, discussions about limiting therapy or do-not-resuscitate (DNR) decisions may be regarded as an attempt by the dominant culture to withhold possibly life-sustaining therapy. Some individuals and communities fear being treated “like a guinea pig” and refuse to participate in clinical trials when offered. The sometimes conflicted relationships that poor people have with health care providers and systems related to care at the end of life is again powerfully captured by Moller:

... Perhaps even more poignant than the anger and disappointment of dissatisfied patients is the absence of resentment on the part of those who have every reason to be upset with the care they receive. It is fair to suggest that, for some, this lack of assertiveness and anger has its roots deep within the experience of poverty.

Living every day with chaos, stress, and the indignity of inner-city poverty creates, for many, a level of tolerance that most of us would find intolerable. In this regard, it is not unusual for patients to accept care with which they are unhappy because they have accepted a lifetime of economic and social indignities about which they are unhappy. In a strange sense, many patients often felt their suffering in the face of disease was just, “one more bad thing to endure.” Thus despite many variations in form and meaning, disease and dying are often borne with a sense of equanimity that flows from constant adjustments required by a life lived in poverty [p. 1].10

Matt, a Patient with Squamous Cell Cancer

Matt, a 58-year-old African-American man, grew up in Georgia. He was drafted after high school. When he finished his military service in Vietnam, he settled in a West Coast city far away from his family. He lost touch with his family after years of “serious” alcohol and drug abuse, despite periods of sobriety. Matt’s other medical problems include hypertension,
posttraumatic stress disorder, and an 80-pack-year history of smoking. Matt had been sober for 5 years until he experienced flashbacks of Vietnam following the invasion of Iraq, at which time he tried to hang himself. He was hospitalized in a psych unit and responded to antidepressants and group therapy. Six months later, after persistent sore throat, difficulty swallowing, and weight loss, he went to a drop-in clinic at the food bank. He was sent to the emergency room at a teaching hospital and was eventually diagnosed with stage IV squamous cell cancer of the hypopharynx. Matt had a radical neck dissection, chemotherapy, and radiation therapy. He agreed to placement in a nursing home while he was receiving chemotherapy and radiation therapy (RT). Matt returned to the oncology clinic for follow-up for an enlarged neck mass, and the oncology fellow told him that he suspected tumor recurrence and wondered if Matt had thought about hospice. Matt became angry and expressed doubt that this doctor knew what he was doing, because the ENT doctor (also white) had told him the mass may be inflammation caused by the RT. He was clear that he was not ready to die and insisted that he was not afraid. Matt felt like he had gotten his life back and wasn’t ready to “cash it in yet—I don’t want anything to do with hospice.” His supports included a local church that ministers to the urban poor, his AA sponsor, and a case manager who has followed him since his hospitalization.

Matt’s story raises a number of complex issues influenced by culture, historical discrimination, and the process of end-of-life decision-making. For some African Americans, according to Crawley, death is seen as a struggle to overcome and, for others, a welcomed friend that precedes going home to heaven. Matt was not ready to go home; while his church and religion were sources of support, he regarded death as a struggle to be overcome. Matt received care in a public hospital from an oncology fellow whose different race, education, and occupation may have contributed to different world views. When to introduce the option of hospice is difficult. For some patients, poor and nonpoor alike, hospice is equated with death? Many of these questions are not unique to the poor and nonpoor alike; hospice is equated with giving up, introducing the option of hospice is difficult. For some patients, the standard for end-of-life care, are infrequently used by African Americans.

Where and How Homeless People Die

Limited data are available regarding the socioeconomic factors, places of death, and immediate causes of death of the homeless. Most poor people, like those who are not poor, die in institutions. For those who are homeless, dying on the street or in jail is another fact of life.

In 2003, 169 homeless persons died in San Francisco. The profile of the homeless who died were: male (85%), average age of 42 years, and disproportionately more whites and African Americans than live in San Francisco. Drug and alcohol were directly associated with 60% of these deaths. Chronic alcohol abuse and acute alcohol intoxication were also listed as causes of death in the homeless in Georgia. Hypothermia was also noted as a cause of death among the homeless in Chicago and in Georgia. Accidental deaths due to fires, falls, and pedestrian–motor vehicle accidents, plus drowning and violent deaths related to homicide and suicide were also reported in the homeless.

Researchers in Boston studied the use of health care by the homeless for the year prior to their deaths. Chart reviews were completed for all patients reported to the state death registry who had participated in a health care program for the homeless. The actual circumstances of the death were not studied; however, the causes of death as listed on death certificates were noted. For the 5-year study period, 558 deaths were reported. Unlike the previous results, which looked at coroner’s cases, 81% of the deaths were attributed to natural causes (such as HIV/AIDS-related conditions, heart disease, cancer, and other unspecified causes), and only 19% were due to external causes such as homicide, suicide, motor vehicle injuries, and drug overdoses. Similar to the homeless who died in San Francisco, most were male (86%), between 25 and 44 years of age (56%), white (59%), and had a history of substance abuse (76% used alcohol). In addition, 28% were mentally ill.

Palliative Care Models for Working with the Poor

Several hospitals serving the urban poor have developed palliative care programs to address their specific needs. The longest-running program (since 1986) is a nurse-directed program that serves critically ill patients who are unlikely to survive hospitalization in a trauma level I hospital in the Midwest. This supportive care team has documented decreased use of health care resources and family satisfaction. Another program, an interdisciplinary palliative care service based in a public hospital, follows patients and their families in the community and serves as a bridge when the patient is transferred to a nursing home or hospice for continuing care.
program was an interdisciplinary palliative care inpatient consult service that served a racially and ethnically diverse community (with many non-English–speaking patients). Despite achieving improved symptom management, increased patient/family participation in decision-making, and documentation of barriers to optimum end-of-life care, this program was eliminated because it was not able to generate sufficient revenue to sustain itself.44

Strategies for Working with the Poor and Homeless Who Happen to Be Dying

Working with the very poor can be challenging. Generations of internalized hopelessness, poor self-awareness, differing perceptions of time (everything seeming to take much longer), and difficulties navigating the many bureaucracies necessary to obtain services surely frustrate patients and caregivers alike.45 Some have suggested modifying expectations to these realities and recognizing small successes as strategies to address these factors.45

On the other hand, for many persons who live on the street, survival skills are keenly developed. Knowing when a food bank opens, where to get clothing, when shelter-bed waiting lines begin to form, or how to get benefit checks without an address requires remarkable ingenuity and discipline. Needless to say, as with persons who are not poor, wide variations in abilities, resources, and relationships with health care professionals exist.

Obviously, stable housing is critical to providing palliative care. Researchers noted the benefits of supportive housing to minority elders in East Harlem, including better psychological outcomes and increased use of informal supports.46 In a qualitative study of nurses who care for persons who are disenfranchised, the researcher used the metaphor of a wall to describe the separation that nurses believed their clients experienced from society.45 The disenfranchised in this study included the poor, mentally ill, immigrants, persons with substance abuse, and/or those with stigmatizing life-threatening illness. The nurses described three key themes in how they engaged their disenfranchised clients: (1) making a human connection with the client, (2) creating a community connection for their disconnected clients, and (3) making self-care possible.

In summary, developing therapeutic relationships with the poor and homeless requires (1) expecting the person’s trust to be earned over time (sometimes a long time) and not be taken for granted; (2) respecting the person’s humanity, no matter how they look, what they say, and what feelings in us they evoke; (3) appreciating the person’s unique story as influencing his/her response to illness and death; and, finally, (4) recognizing and addressing maladaptive behaviors.29,39,48 Table 36–6 includes a list of helpful suggestions to reach a difficult-to-engage client.

<table>

<th>Helpful Suggestions When Engaging a Difficult-to-Engage Client</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Address anyone over 40 years of age by the title of Mr. or Ms. Ask permission to be on a first-name basis.</td>
<td></td>
</tr>
<tr>
<td>• Do not hesitate to shake hands.</td>
<td></td>
</tr>
<tr>
<td>• Be prepared to meet people who are more intelligent, more perceptive, and more wounded than you expect.</td>
<td></td>
</tr>
<tr>
<td>• Be tolerant. How would you react if you were in that situation?</td>
<td></td>
</tr>
<tr>
<td>• Don’t make promises you can’t keep.</td>
<td></td>
</tr>
<tr>
<td>• Don’t take it personally.</td>
<td></td>
</tr>
<tr>
<td>• Taking time out helps prevent burnout.</td>
<td></td>
</tr>
<tr>
<td>• Get to know the community.</td>
<td></td>
</tr>
<tr>
<td>• If you feel you have to save the human race, do it one person at a time.</td>
<td></td>
</tr>
<tr>
<td>• Providing material assistance (e.g., clean socks, food, hygiene kits) opens people up.</td>
<td></td>
</tr>
<tr>
<td>• Usually the most difficult clients are those most in need. Throw the word noncompliant out of your vocabulary.</td>
<td></td>
</tr>
<tr>
<td>• Make eye contact. If the person does not like eye contact or becomes agitated, avoid using it.</td>
<td></td>
</tr>
<tr>
<td>• Keep in mind that people who live intense lives may not particularly like unasked-for physical contact.</td>
<td></td>
</tr>
<tr>
<td>• Don’t be afraid to ask “stupid” questions; patients’ answers are better than your assumptions.</td>
<td></td>
</tr>
<tr>
<td>• Adjust your expectations and accept small victories with satisfaction.</td>
<td></td>
</tr>
</tbody>
</table>

In addition to the interpersonal interventions to engage the client in a therapeutic interaction, nurses are often required to become knowledgeable about the availability of and the services provided by community agencies. Knowing which agencies or services are involved with a client and communicating with them assures consistency of approach and continuity of care. Advocacy is often required to access services such as pain management, substance abuse treatment, mental health services, and social services for housing and money management. To truly improve end-of-life care for the poor, nurses need to advocate for public policies that assure access to safe and stable housing, health insurance, and client-centered, community-based primary care.

**Conclusion**

Providing palliative care to the poor, especially the homeless, is extremely challenging. Comorbid illnesses, illnesses associated with poverty, and clarifying the etiology of presenting symptoms may seem almost impossible at times. Psychosocial risk factors and strained relationships with health care providers sometimes result in the client receiving futile or unwanted medical interventions at an advanced stage of illness. Clarifying with a patient what constitutes a good death for him or her can be humbling when the patient tells you he or she wants medical interventions at an advanced stage of illness. Clarifying with them assures consistency of approach and continuity of care needs of this vulnerable population will require innovative practice and education models.

Patients with Acquired Immunodeficiency Syndrome

I thank God that there are medications to treat AIDS, but there are serious side effects and they can make you feel quite sick. Yet, I want to live and I will do everything possible to stay alive. Some people say AIDS is now a chronic disease. There are other medications to treat my symptoms, and there is my belief in God that lifts my spirit. My family helps me care for my kids, but it is hard on everyone. We all need support because we are all suffering one way or another.—A patient

Key Points

- With HIV/AIDS, the severity, complexity, and unpredictability of the illness trajectory have blurred the distinction between curative and palliative care.
- The focus of AIDS care must be on improving quality of life by providing care for the management of pain and other symptoms, while addressing the emotional, social, and spiritual needs of patients and their families throughout the illness trajectory.
- With up-to-date knowledge regarding HIV disease, including changes in epidemiology, diagnostic testing, treatment options, and available resources, nurses can offer effective and compassionate care to patients and families at all stages of HIV disease.

In 20 years, acquired immunodeficiency syndrome (AIDS) has escalated from a series of outbreaks in scattered communities in the United States and Europe to a global health crisis. Although the emerging biomedical paradigm of highly active antiretroviral therapy (HAART) has significantly reduced the mortality from human immunodeficiency virus (HIV) in the developed world and has transformed AIDS into a manageable chronic illness, the reality worldwide is that people are not “living with AIDS,” but rather, “dying from AIDS” due to a lack of access to medications and appropriate health care. Even in developed countries, AIDS remains the leading cause of serious illness and death for young adults, and at this point in time, there is a false dichotomy created between disease-specific, curative therapies and symptom-specific palliative therapies. AIDS has stimulated the need to evaluate clinical practice when curative and palliative care interface and raises some interesting and interconnected issues about the care of individuals with life-threatening, progressive illnesses. Both the public and health professionals have been troubled by the reality of overtreatment and undertreatment of pain and symptoms in individuals with life-threatening illnesses, particularly at the end of life. Such concern extends to the care of patients with HIV and the resultant illness of AIDS because no cure has yet been found. The focus of care must, therefore, be on improving quality of life by providing palliative care for the management of pain and other physical symptoms while addressing the emotional, social, and spiritual needs of patients and their families throughout the illness trajectory. Even though current therapies have increased the life expectancy of people with HIV/AIDS, the chance of their experiencing symptoms related not only to the disease but to the effects of therapies also increases. Furthermore, palliative measures can be beneficial in ensuring tolerance of and adherence to difficult pharmacological regimens.

Although little attention has been given in the past to palliative care as a component of AIDS care, it is now realized that the palliation of pain, symptoms, and suffering must occur throughout the course of a life-threatening disease, not just in
Overview and Update: Incidence, Historical Background, Epidemiology, and Pathogenesis

Incidence of HIV/AIDS

HIV/AIDS is a worldwide epidemic affecting more than 40 million people. An estimated 5 million acquired HIV in 2003, with an estimated 3 million people dying from AIDS. The Centers for Disease Control and Prevention (CDC) in 2004 reported that through December 2002, there were more than 877,275 reported cases in the United States since the beginning of the epidemic. 718,002 cases were males, 159,271 cases females, and 9,300 cases estimated in children under age 13. In the United States, the estimated number of deaths of persons with AIDS is 501,669, including 496,354 adults and adolescents, and 5,315 children under age 15. HIV is the leading cause of death of all Americans between the ages of 25 and 44 years, with the highest incidence and prevalence now among African Americans, women, and heterosexuals. Given that there are no approved vaccines against HIV/AIDS or cures for the disease, AIDS remains a life-threatening and progressive illness that marks the final stage of a chronic viral illness, identified by the occurrence of particular opportunistic infections, cancers, and neurological manifestations.

Historical Background of HIV/AIDS

In the early 1980s, cases were reported of previously healthy homosexual men who were diagnosed with Pneumocystis carinii pneumonia and an extremely rare tumor known as Kaposi’s sarcoma (KS). The number of cases doubled every 6 months, with further occurrence of unusual fungal, viral, and parasitic infections, and it was realized that the immune systems of these individuals were being compromised. Over time, the CDC learned that a complex of diseases producing immunocompetence was experienced outside the homosexual community, among heterosexual partners, intravenous (IV) substance users, persons with hemophilia, individuals receiving infected blood products, and children born to women with the disease. These epidemiological changes alerted health professionals to the existence of an infectious agent transmitted via infected body fluids, particularly through sexual transmission and blood products.

Origins of HIV can be traced through serum studies to 1959, when crossover mechanisms between humans and primates via animal bites or scratches in Africa led to HIV transmission. In 1981, the virus was identified and named lymphadenopathy-associated virus (LAV). By 1984, the term had been changed to human T-lymphocytic virus type III (HTLV-III), and in 1986 renamed the human immunodeficiency virus type 1 (HIV-1). HIV-1 accounts for nearly all the cases reported in the United States, while a second strain, HIV-2, accounts for nearly all the cases reported in West Africa. There have only been 17 cases of HIV-2 reported in the United States, the majority being immigrants from Africa.

Globally, AIDS is characterized as a volatile, unstable, and dynamic epidemic, which has spread to new countries around the world. It has become increasingly complex due to the viruses’ ability to mutate and crosses all socioeconomic, cultural, political, and geographic borders. To date, scientific progress has been made in combating the infection: (1) the virus has been identified; (2) a blood-screening program has been implemented; (3) vaccines are being tested; (4) biological and behavioral cofactors have been identified related to infection and disease progression; (5) prophylactic treatments are available to prevent opportunistic infections; (6) newly developed HIV RNA quantitative assays, which measure viral load (VL), have become available to guide the treatment of the disease; and (7) the latest advances in treatment involve the use of combination antiretroviral therapies. However, epidemiological evidence heightens concern regarding changes in the population affected and the morbidity and mortality still associated with the disease.

HIV Epidemiology

Epidemiological studies confirm that HIV-1 is transmitted through semen, cervical and vaginal secretions, breast milk, contaminated drug equipment, transfusions and blood products, tissue transplants, perinatal exposure, and occupational exposure in health care settings. Although HIV diagnosis has remained stable in the United States from 1999 to 2002, the rate of HIV infection has dramatically increased among African Americans (75.6 per 100,000), compared with Hispanics (29.3 per 100,000) and Caucasians (8.0 per 100,000). Diagnosis rates remain higher among males (27.7 per 100,000) than females (10.7 per 100,000). Furthermore, the rate of HIV diagnosis rose 5% per year among men who have sex with men of all races, and remains stable among heterosexuals and IV substance abusers.

In the HAART era, there has been a decrease in the incidence of KS and cervical cancer, although the incidence of non-Hodgkin’s lymphoma has not decreased. In contrast, in the HAART period, the incidence of lung cancer, Hodgkin’s disease, anorectal cancer, melanoma, and head and neck cancers has increased.

Until a vaccine is available, sex education, the use of condoms, and drug-abuse treatment, including the provision of clean needles, have been shown to limit the horizontal spread...
HIV Pathogenesis and Classification

Like all viruses, the HIV virus survives by reproducing itself in a host cell, usurping the genetic machinery of that cell, and eventually destroying the cell. The HIV is a retrovirus whose life cycle consists of (1) attachment of the virus to the cell, which is affected by cofactors that influence the virus's ability to enter the host cell; (2) uncoating of the virus; (3) reverse transcription by an enzyme called reverse transcriptase, which converts two strands of viral RNA to DNA; (4) integration of newly synthesized proviral DNA into the cell nucleus, assisted by the viral enzyme integrase, which becomes the template for new viral components; (5) transcription of proviral DNA into messenger RNA; (6) movement of messenger RNA outside the cell nucleus, where it is translated into viral proteins and enzymes; and (7) assembly and release of mature virus particles out of the host cell.

The host cell therefore produces viral proteins instead of the cell's normal regulatory proteins, resulting in the eventual destruction of the host cell. Given that the virus has an affinity for CD4 molecules, any cells that have the CD4 molecule on their surface, such as T lymphocytes and macrophages, become major viral targets. Recently, research has identified that chemokines and chemokine receptors play important roles in HIV pathogenesis by inhibiting HIV infection. Because CD4 cells are the master coordinators of the immune response, chronic destruction of these cells severely compromises individuals' immune status, leaving them susceptible to opportunistic infections. Macrophages are also directly targeted by the virus and may serve as reservoirs for the virus for months after initial infection, as well as contributing to HIV-related dementia and other neurological syndromes. HIV and AIDS are not synonymous terms but, rather, refer to the natural history or progression of the infection, ranging from asymptomatic infection to life-threatening illness characterized by opportunistic infections and cancers. This continuum of illness is associated with a decrease in CD4 cell count and a rise in HIV-RNA VL. In monitoring disease progression, it should be noted, however, that although low CD4 cell counts are generally correlated with high VLs, some patients with low CD4 counts have low VLs and vice versa. The most reliable current measurement of HIV activity, therefore, is the VL, and the more consistent surrogate marker is the percentage of lymphocytes that are CD4 cells, rather than the absolute CD4 cell count.

In 1993, the CDC reclassified HIV disease according to the CD4 T lymphocyte count and clinical conditions associated with HIV infection. The classification of HIV disease is as follows: Primary or acute infection occurs when the virus enters the body and replicates in large numbers in the blood. This leads to an initial decrease in the number of T cells. Viral load climbs during the first 2 weeks of the infection. Within 5 to 30 days of infection, the individual experiences flu-like symptoms characteristic of a viremia such as fever, sore throat, skin rash, lymphadenopathy, and myalgia. Other manifestations of primary HIV infection include fatigue, splenomegaly, anorexia, nausea and vomiting, meningitis, retro-orbital pain, neuropathy, and mucocutaneous ulceration. The production of HIV antibodies results in seroconversion, which generally occurs within 6 to 12 weeks of the initial infection. The amount of virus present after the initial viremia and the immune response is called the viral set point.

Clinical latency refers to the chronic, clinically asymptomatic state in which there is a decreased VL and resolution of symptoms of the primary infection. It was previously thought that in this period, the virus lay dormant in the host cells for a period of 5 to 7 years. However, recent advances in the understanding of the pathogenesis of the virus reveal that there is continuous viral replication in the lymph nodes. Because more than 10 billion copies of the virus can be made every day during this period, early medical intervention with combination antiretroviral therapy is recommended.

Early symptomatic stage occurs after years of infection and is apparent by conditions indicative primarily of defects in cell-mediated immunity. Early symptomatic infection occurs when CD4 counts fall below 500 cells/mm$^3$ and the HIV VL copy count increases above 10,000/mL up to 100,000/mL, which indicates a moderate risk of HIV progression and a median time to death of 6.8 years. There are frequently mucosal clues, ranging from oral candidiasis and hairy leukoplakia to ulcerative lesions. Gynecological infections are the most common reasons women have a medical examination. There are also dermatological manifestations, which include bacterial, fungal, viral, neoplastic, and other conditions such as exacerbation of psoriasis, severe pruritus, or the development of recurrent pruritic papules.

Late symptomatic stage begins when the CD4 count drops below 200 cells/mm$^3$ and the VL increases above 100,000/mL. This CD4 level is recognized by the CDC as the case definition for AIDS. Severe opportunistic infections or cancers characterize this stage and result in multiple severe symptoms. In addition to such illnesses as KS, Pneumocystis carinii pneumonia, HIV encephalopathy, and HIV wasting, diseases such as pulmonary tuberculosis, recurrent bacterial infections, and invasive cervical cancer have been added to the list of AIDS-indicative illnesses. Advanced HIV disease stage occurs when the CD4 cell count drops below 50 cells/mm$^3$ and the immune system is so impaired that death is likely within 1 year. Common conditions are central nervous system (CNS) non-Hodgkin's lymphoma, KS, cytomegalovirus (CMV) retinitis, or Mycobacterium avium complex (MAC). Unfortunately, persons with...
advanced HIV disease diagnosed with AIDS increasingly represents persons whose diagnosis was too late for them to benefit from treatment, persons who either did not seek or had no access to care, or persons for whom treatment failed. In the late stages of the disease, most individuals have health problems such as pneumonia, oral candidiasis, depression, dementia, skin problems, anxiety, incontinence, fatigue, isolation, bed dependency, wasting syndrome, and significant pain. Research regarding AIDS patients experiencing advanced disease confirms the multitude of patient symptoms and factors that contribute to mortality. In a study of 83 hospitalized AIDS patients, factors contributing to higher mortality include the type of opportunistic infections, serum albumin level, total lymphocyte count, weight, CD4 count, and neurological manifestations. Of 363 patients with AIDS referred to community palliative care services, the most severe problems throughout care were patient and family anxiety and symptom control. In the last month of life, a retrospective study of 50 men who died from AIDS indicated that the most distressing symptoms included pain, dyspnea, diarrhea, confusion, dementia, difficulty swallowing and eating, and loss of vision. Dehydration, malnutrition, and peripheral neuropathy were also important problems.

Palliative Care as a Natural Evolution in HIV/AIDS Care

From the earliest stages of HIV disease, symptom control becomes an important goal of medical and nursing care to maintain the patient’s quality of life. Palliative care for patients with HIV/AIDS should therefore be viewed not as an approach to care only in the advanced stage of the illness, but as an aspect of care that begins in the early stage of illness and continues as the disease progresses.

With the occurrence of opportunistic infections, specific cancers, and neurological manifestations, AIDS involves multiple symptoms not only from the disease processes but also from the side effects of medications and other therapies. Patients with AIDS present with complex care issues because they experience bouts of severe illness and debilitation alternating with periods of symptom stabilization. In one model of care, AIDS palliation begins when active treatment ends. Although this model limits service overlap and is economical, it creates not only the ethical issue of when to shift from a curative to a palliative focus, but also promotes discontinuity of care and possible discrimination. In contrast, a second model of AIDS care recognizes that AIDS treatment is primarily palliative, directed toward minimizing symptoms and maximizing the quality of life, and necessitates the use of antiretroviral drugs, treatment of infections and neoplasms, and provision of high levels of support to promote the patient’s quality of life over many years of the illness. Selwyn and Rivard emphasize that although AIDS is no longer a uniformly fatal disease, it is an important cause of mortality, particularly for young adults and ethnically diverse populations with comorbidities such as hepatitis B and C, end-organ failure, and various malignancies.

Although thousands of individuals have suffered and died from AIDS each year, the palliative care needs of HIV/AIDS patients have been largely neglected by organizations involved in medical care. This has occurred because the division between curative-aggressive care and supportive-palliative care is less well defined and more variable than in other life-threatening illnesses such as cancer. With HIV/AIDS, the severity, complexity, and unpredictability of the illness trajectory have blurred the distinction between curative and palliative care. Other challenges associated with HIV/AIDS are the societal stigmatization of the disease and, therefore, the greater emotional, social, and spiritual needs of those experiencing the illness, as well as their family and professional caregivers who experience their own grief and bereavement processes.

Resources aimed at prevention, health promotion and maintenance, and end-of-life care must be available through health care policies and legislation. Not only the treatment of chronic debilitating conditions, but also the treatment of superimposed acute opportunistic infections and related symptoms is necessary to maintain quality of life. For example, IV therapy and blood transfusions, as well as health prevention measures such as ongoing IV therapies to prevent blindness from CMV retinitis, must be available to patients with AIDS to maintain their quality of life.

Palliative care is therefore a natural evolution in AIDS care. Core issues of comfort and function, fundamental to palliative care, must be addressed throughout the course of the illness, and may be concurrent with restorative or curative therapies for persons with AIDS. The management decisions for patients with advanced AIDS will revolve around the ratio between benefits and burdens of the various diagnostic and treatment modalities, and the patient’s expectations and goals, as well as anticipated problems. In the face of advanced HIV disease, health care providers and patients must determine the balance between aggressive and supportive efforts, particularly when increasing debility, wasting, and deteriorating cognitive function are evident. At this point, the complex needs of patients and families with HIV/AIDS require the coordinated care of an interdisciplinary palliative care team, involving physicians, advanced practice nurses, staff nurses, social workers, dietitians, physiotherapists, and clergy. Given that in palliative care the unit of care is the patient and family, the palliative care team offers support not only for patients to live as fully as possible until death, but also for the family to help them to cope during the patient’s illness and in their own bereavement.

Palliative care core precepts of respect for patient goals, preferences, and choices, comprehensive caring, and acknowledgment of caregivers’ concerns support the holistic and comprehensive approach to care needed by individuals and families with HIV/AIDS. The components of high-quality HIV/AIDS palliative care, as identified by health care providers, include competent, skilled practitioners; confidential, nondiscriminatory, culturally sensitive care; flexible and responsive care; collaborative and coordinated care; and fair access to care.
Although the hospice and palliative care movement developed as a community response to those who were dying, primarily of cancer, the advent of the AIDS epidemic made it necessary for hospices to begin admitting patients with AIDS. This meant applying the old model of cancer care to patients with a new infectious, progressive, and terminal disease. Unlike the course of cancer, which is relatively predictable once the disease progresses beyond cure, AIDS patients experience a series of life-threatening opportunistic infections. It is not until wasting becomes apparent that the course of AIDS achieves the predictability of cancer. Furthermore, while the underlying goal of AIDS care remains one of palliation, short-term aggressive therapies are still needed to treat opportunistic infections. Also, unlike cancer palliation, AIDS palliation deals with a fatal infectious disease of primarily younger people, which requires ongoing infection control and the management of symptoms.

**Barriers to Palliative Care**

The neglect of the palliative care needs of patients with HIV disease also relates to certain barriers to care, such as reimbursement issues. Specifically, public and private third-party payers have reimbursed end-of-life care only when physicians have verified a life expectancy of less than 6 months to live. Given the unpredictability of the illness trajectory, many patients with AIDS have been denied access to hospice care. Currently, these policies are under review, and the 6-month limitation is being extended so that patients with AIDS will be eligible for comprehensive care, with control of pain and other symptoms along with psychological and spiritual support offered by hospice/palliative care.

As a second barrier to hospice/palliative care, patients with AIDS have been denied, until recently, access because of the need to continue antiretroviral therapies and other medications to prevent opportunistic infections. Given that the estimated cost of treatment for AIDS patients in hospices could amount to twice the cost of treating patients with cancer, particularly when the costs of medications are included, cost remains an important issue for hospices. Financing of such therapies for patients with AIDS is now being addressed by hospice/palliative care organizations.

The third barrier to palliative care is the patients themselves, many of whom are young, clinging to the hope of a cure for AIDS and unwilling to accept hospice care. However, the current emphasis on beginning palliative care at the time of diagnosis of a life-threatening illness may shift the perception of palliative care as only end-of-life care, and help promote palliative care as an aggressive approach to care throughout the course of the illness to ensure their quality of life. Indeed, media and Internet coverage of government and private initiatives to improve the care of the seriously and terminally ill in the United States is informing patients, families, and nurses of the philosophy and precepts of palliative care, the availability of palliative care for life-defining illnesses, and the rights of patients to receive excellent end-of-life care, as well as the obligations of health professionals to provide such care across health care settings.

**Criteria for Palliative Care**

Grothe and Brody suggest that four criteria be considered regarding the admission of AIDS patients to hospice: functional ability, statistical prognosis, CD4 count and VL, and history of opportunistic infections. These criteria give a better understanding of the patient’s prognosis and needs. The complex needs of patients with advanced AIDS also indicate the need for an interdisciplinary approach to care offered by hospice/palliative care. Bloom and Flannery encourage the continual review of hospice policies in accordance with the changes in the disease and encourage change in the community to provide an effective continuum of care. Indeed, developing different models of care such as enhanced home care, hospice care, day care, or partnerships with community hospitals or agencies and conducting cost-benefit analysis will be important in meeting the health care needs of patients with AIDS and their families in the future.

Important advances are currently being made in the field of palliative medicine and nursing, involving an active set of behaviors that continue throughout the caregiving process to manage the pain and suffering of individuals with HIV/AIDS. Health professionals have the responsibility to be knowledgeable about the various treatment options and resources available for pain and symptom management. They must know about pharmacological agents’ actions, side effects, and interactions, as well as alternative routes of medication administration. And they must be able to inform patients of their options for care—documenting their preferences, wishes, and choices; performing a complete history and physical assessment; and collaborating with other members of the interdisciplinary team to develop and implement a comprehensive plan of care.

**Health Promotion and Maintenance in Promoting the Quality of Life of Persons with HIV/AIDS**

As palliative care becomes an increasingly important component of AIDS care from diagnosis to death, and given the definition of palliative care as the comprehensive management of the physical, psychological, social, spiritual, and existential needs of patients with incurable progressive illness, palliative care must involve ongoing prevention, health promotion, and health maintenance to promote the patient’s quality of life throughout the illness trajectory. With HIV/AIDS, health promotion and maintenance involves promoting behaviors that will prevent or decrease the occurrence of opportunistic infections and AIDS-indicator diseases, promoting prophylactic and therapeutic treatment of AIDS-indicator conditions, and preventing behaviors that promote disease expression.

With no current prospect for cure, the health management of patients with HIV/AIDS is directed toward prolonging survival and maintaining quality of life. Nurses generally refer to quality of life as the impact of sickness and health care on an ill person’s daily activities and sense of well-being. Furthermore, quality of life varies with disease progression from HIV...
to AIDS. To understand quality of life means to understand the patient’s perceptions of his or her ability to control the physical, emotional, social, cognitive, and spiritual aspects of the illness.42 Quality of life is therefore associated with health maintenance for individuals with HIV/AIDS, particularly as it relates to functioning in activities of daily living, social functioning, and physical and emotional symptoms.43 In a study regarding the functional quality of life of 142 men and women with AIDS, Vosvick and colleagues44 concluded that maladaptive coping strategies were associated with lower levels of energy and social functioning and that severe pain interfered with daily living tasks and was associated with lower levels of functional quality of life (physical functioning, energy/fatigue, social functioning, and role functioning). Therefore, health promotion interventions should be aimed at developing adaptive coping strategies and improving pain management.

Health promotion and maintenance for patients with HIV/AIDS must acknowledge patients’ perceived health care needs. Based on a study of 386 HIV-infected persons, it was determined that the health care challenges perceived by patients with HIV/AIDS across hospital, outpatient, home, and long-term care settings included decreased endurance, physical mobility, and sensory perception, as well as financial issues—specifically lack of income and resources to cover living and health care expenses.45 Furthermore, Kemppainen46 reported, based on a sample of 162 hospitalized men and women with AIDS, that the strongest predictor of decreased quality of life was depression, which accounted for 23% of the variance, with symptoms accounting for 9.75% and female gender accounting for an additional 8%. In addition, active involvement in the process of nursing care contributed 13.4% to the variance in quality of life. These results indicate the health care challenges and physical, emotional, and interactional needs of patients with AIDS and, that in addition to managing pain and other symptoms, a comprehensive and compassionate approach to care is necessary as the illness progresses. Furthermore, enhancing immunocompetence is critical at all stages of illness, as well as treating the symptoms brought on by the disease or related to prophylactic or treatment therapies. Palliation of physical, emotional, and spiritual symptoms, particularly as experienced in the late symptomatic and advanced stages of HIV disease, is considered the final stage of a health-and-disease-prevention approach and will be discussed later in this chapter.47

Through all stages of HIV disease, health can be promoted and maintained through diet, micronutrients, exercise, reduction of stress and negative emotions, symptom surveillance, and the use of prophylactic therapies to prevent opportunistic infections or AIDS-related complications.

Diet

A health-promoting diet is essential for optimal functioning of the immune system. Deficiencies in calorie and protein intake impair cell-mediated immunity, phagocytic function, and antibody response. Therefore, an alteration in nutrition is associated with impaired immune system function, secondary infections, disease progression, psychological distress, and fatigue. In patients with AIDS, common nutritional problems are weight loss, vitamin and mineral deficiencies, loss of muscle mass, and loss or redistribution of fat mass. The redistribution of fat is characterized by increased abdominal girth, loss of fat from the face, and a “buffalo hump” on the back of the neck, which may be due to the administration of protease inhibitors.47 Patients with HIV/AIDS often have reduced food or caloric intake, malabsorption, and altered metabolism. Reduced food or caloric intake is frequently due to diseases of the mouth and oropharynx, such as oral candidiasis, anular cheilitis, gingivitis, herpes simplex, and hairy leukoplakia.48 Incidence of diseases of the gastrointestinal (GI) tract that can cause malabsorption, such as CMV, MAC, cryptosporidiosis, and KS increases for individuals with CD4 counts of 50 or less, and may adversely affect their nutritional status.49 Metabolic alterations may be due to HIV infection or secondary infections, as well as abnormalities in carbohydrate, fat, and protein metabolism.47 The Task Force on Nutrition in AIDS (1989) recommended that the goals of sound nutritional management should include: (1) provision of adequate nutrients; (2) preservation of lean body mass; and (3) minimization of symptoms associated with malabsorption. Hussein50 believes that a good diet is one of the simplest ways to delay HIV progression and will bolster immune system function and energy levels and help patients live longer and more productive lives. A diet with a variety of foods from the five basic food groups, including 55% of calories from carbohydrates, 15% to 20% of calories from proteins, and 30% of calories from fats, is important in supporting immune function.51 It is recommended to have two or three servings daily from the protein and dairy groups, seven to 12 servings from the starch and grain group, two servings of fruits and vegetables rich in vitamin C, as well as three servings of other fruits and vegetables.10

Micronutrients

Research has indicated that HIV-infected individuals have lower levels than noninfected individuals of magnesium, total carotenes, total choline, and vitamins A and B6, yet higher levels of niacin.52 A linkage has been reported between vitamin A (beta carotene) deficiency and elevated disease progression and mortality.53 Correcting both vitamin A and B6 deficiencies has been hypothesized to restore cell-mediated immunity, and vitamin-supplement trials are underway. Current research supports the increase in dietary intake of n-3 polyunsaturated fatty acids, arginine, and RNA to increase body weight and stave off wasting due to malabsorption. Increase in concentrations of amino acids such as arginine has also been found to preserve lean muscle mass.54

Exercise

A consistent outcome of the effects of exercise on immune function is the increase in natural killer-cell activity, though variable results are reported on the effects of exercise on neutrophil, macrophage, and T and B cell function and proliferation.44 In
a review of exercise studies, LaPerriere and colleagues\textsuperscript{36} reported a trend in CD4 cell count elevation in all but one study, with the greatest effect from aerobic exercise and weight training. The CDC\textsuperscript{36} recommend a physical exercise program of 30 to 45 minutes four or more times a week as a health-promoting activity to increase lung capacity, endurance, energy, and flexibility, and to improve circulation.

Massage has also been linked to natural killer-cell activity and overall immune regulation as reported in a research study of 29 HIV-infected men who received daily massages for 1 month.\textsuperscript{57} Patient reports of less anxiety and greater relaxation related to exercise and massage are regarded by both patients and practitioners as important laboratory markers.\textsuperscript{32}

**Stress and Emotions**

Stress and negative emotions have also been associated with immunosuppression and vulnerability to disease. In a study of 96 HIV-infected homosexual men without symptoms or antiretroviral medication use, Leserman and colleagues\textsuperscript{38} reported that higher cumulative average stressful life events, higher anger scores, lower cumulative average social support, and depressive symptoms were all predictive of a faster progression to both the CDC AIDS classification and a clinical AIDS condition. Stress of living with HIV/AIDS is related to the uncertainty regarding illness progression and prognosis, stigmatization and discrimination, and financial concerns as disabilities increase with advancing disease. Persons with AIDS frequently cite the avoidance of stress as a way of maintaining a sense of well-being.\textsuperscript{59} The use of exercise and massage and other relaxation techniques, such as imagery, meditation, and yoga, are reported as valuable stress-management techniques.\textsuperscript{60} Cognitive-behavioral interventions have also been shown to improve certain aspects of quality of life of women with AIDS (n = 330), specifically in terms of cognitive functioning, health distress, and overall health perceptions. However, no changes were observed in energy/fatigue, pain, or role or social functioning.\textsuperscript{61}

Health promotion also involves health beliefs and coping strategies that support well-being despite protracted illness. A study of 53 patients diagnosed with AIDS demonstrated that long-term survivors used numerous strategies to support their health, such as having the will to live, positive attitudes, feeling in charge, a strong sense of self, expressing their needs, and a sense of humor. Other health-promotion strategies frequently used by these patients included remaining active, seeking medical information, talking to others, socializing and pursuing pleasurable activities, good medical care, and counseling.\textsuperscript{62} Cohen\textsuperscript{38} examined the relationship between the use of humor to cope with stress (coping humor) and perceived social support, depression, anxiety, self-esteem, and stress, based on a sample of 103 HIV/AIDS patients. The results indicated that patients who used more coping humor were less depressed, expressed higher self-esteem, and perceived greater support from friends. However, the use of coping humor did not buffer stress, anxiety, or immune-system functioning. Stress can also be associated with the financial issues experienced by patients with HIV/AIDS.

Therefore, health promotion may involve financial planning, identification of financial resources available through the community, and public assistance offered through Medicaid.

It must also be recognized that additional physical and emotional stress is associated with the use of recreational drugs such as alcohol, chemical stimulants, tobacco, and marijuana because these agents have an immunosuppressant effect and may interfere with health-promoting behaviors.\textsuperscript{64} The use of such substances may also have a negative effect on interpersonal relationships and are associated with a relapse to unsafe sexual practices.\textsuperscript{65} Interventions for health promotion include encouraging patients to participate in self-health groups and harm-reduction programs to deal with substance-abuse problems.

**Symptom Surveillance**

Throughout the course of their illness, individuals with HIV disease require primary care services to identify early signs of opportunistic infections and to minimize related symptoms and complications. This includes a complete health history, physical examination, and laboratory data including determination of immunological and viral status.

**Health History.** In the care of patients with HIV/AIDS, the health history should include the following\textsuperscript{16}:

- History of present illness, including a review of those factors that led to HIV testing
- Past medical history, particularly those conditions that may be exacerbated by HIV disease or its treatments, such as diabetes mellitus, hypertriglyceridemia, or chronic or active hepatitis B infection
- Childhood illnesses and vaccinations for preventing common infections such as polio, DPT, or measles
- Medication history, including the patient’s knowledge of the types of medications, side effects, adverse reactions, drug interactions, and administration recommendations
- Sexual history, regarding sexual behaviors and preferences and history of sexually transmitted diseases, which can exacerbate HIV disease progression
- Lifestyle habits, such as the past and present use of recreational drugs, including alcohol, which may accelerate progression of disease; cigarette smoking, which may suppress appetite or be associated with opportunistic infections such as oral candidiasis, hairy leukoplakia, and bacterial pneumonia
- Dietary habits, including risks related to food-borne illnesses such as hepatitis A
- Travel history, to countries in Asia, Africa, and South America, where the risk of opportunistic infections increase
- Complete systems review, to provide indications of clinical manifestations of new opportunistic infections or cancers, as well as AIDS-related complications both from the disease and its treatments
Physical Examination. A physical exam should begin with a general assessment of vital signs and height and weight, as well as overall appearance and mood. A complete head-to-toe assessment is important and may reveal various findings common to individuals with HIV/AIDS such as:

- Oral cavity assessment may indicate candida, oral hairy leukoplakia, or KS.
- Funduscopic assessment may reveal visual changes associated with CMV retinitis; glaucoma screening annually is also recommended.
- Lymph node assessment may reveal adenopathy detected at any stage of disease, yet is indicative of disease progression.
- Dermatological assessment may indicate various cutaneous manifestations that occur throughout the course of the illness such as HIV exanthema, KS, or infectious complications such as dermatomicosis.
- Neuromuscular assessment may indicate various central, peripheral, or autonomic nervous systems disorders and signs and symptoms of conditions such as meningitis, encephalitis, dementia, or peripheral neuropathies.
- Cardiovascular assessment may reveal cardiomyopathy related to the use of antiretroviral therapy.
- GI assessment may indicate organomegaly, specifically splenomegaly or hepatomegaly, particularly in patients with a history of substance abuse, as well as signs related to parasitic intestinal infections; annual stool of guaiac and rectal examination, as well as sigmoidoscopy every 5 years, are also parts of health maintenance.
- Reproductive system assessment may reveal occult sexually transmitted diseases or malignancies, as well vaginal candidiasis, cervical dysplasia, pelvic inflammatory disease, or rectal lesions in women with HIV/AIDS, as well as urethral discharge and rectal lesions or malignancies in HIV-infected men. Health maintenance in individuals with HIV/AIDS also includes annual mammograms in women, as well as testicular exams in men and prostate-specific antigen (PSA) annually.

Laboratory Data. CD4 counts, both the absolute numbers and the CD4 percentages, should be evaluated to assist the health practitioner in therapeutic decision-making about treatments of opportunistic infections and antiretroviral therapy. Quantitative RNA determination or VL is also an important marker for disease progression and to measure the effectiveness of antiretroviral therapy. The DHHS’s Panel on Clinical Practices for the Treatment of HIV recommends that VLs be measured upon diagnosis and every 3 to 4 months subsequently. CD4 cell counts should also be measured at the time of diagnosis in an untreated patient and every 3 to 6 months afterward. Immediately before a patient is started on HAART, the patient’s HIV-RNA (VL) should be measured, and again 2 to 8 weeks after treatment is initiated, to determine the effectiveness of the therapy. With adherence to the medication schedule, it is expected that the HIV-RNA will decrease by approximately 1.0 log10 and will continue to decline over the next 16 to 20 weeks until the VL has reached undetectable levels (<50 copies/mL). If a patient does not significantly respond to therapy, the clinician should evaluate adherence, repeat the test, perform a genotyping or phenotyping resistance assay, and rule out malabsorption or drug interactions. It is anticipated that patients with low VLs and high baseline CD4 cell counts will respond positively to therapy.

The decision regarding laboratory testing is based on the stage of HIV disease, the medical processes warranting initial assessment or follow-up, and consideration of the patient-benefit-to-burden ratio. Complete blood counts are often measured with each VL determination or with a change of antiretroviral therapy, particularly with patients on drugs known to cause anemia. Chemistry profiles are done to assess liver function, lipid status, and glycemia every 3 to 6 months or with a change in therapy, and are determined by the patient’s antiretroviral therapy, baseline determinations, and co-infections. Abnormalities in these profiles may occur as a result of antiretroviral therapy. Increasing hepatic dysfunction is evident by elevations in the serum transaminases (AST, ALT, ALP, LDH). Blood work should also include hepatitis C serology (antibody), hepatitis B serology and Toxoplasma IgG serology.

Urine analysis should be done annually unless the person is on antiretroviral therapy, which may require more frequent follow-up to check for toxicity. Annual Papanicolaou (Pap) smears are also indicated, with recommendations for Pap smears every 3 to 6 months in HIV-infected women who are symptomatic. Syphilis studies should be done annually; however, patients with low positive titers should have follow-up testing at 3, 6, 9, 12, and 24 months. Gonorrhea and chlamydia tests are encouraged every 6 to 12 months if the patient is sexually active. In addition, CMV serology for patients with CD4 cell counts under 100 cells/mm3 should be measured every 6 months. Individuals with CD4 cell counts below 100 cells/mm3 and who had negative toxoplasmosis antibodies at baseline should also be tested and started on TMP-SMZ (Bactrim) for prophylaxis.

Annual tuberculin skin testing (TST) is also important for HIV-infected individuals. A TST is considered positive in patients with induration of greater than or equal to 5 mm. With a positive TST, a yearly chest radiograph is warranted.

Prophylaxis

The primary strategy to prevent the development of opportunistic infections is to avoid exposure to microorganisms in the environment. Secondly, the immune system can be supported and maintained through the administration of prophylactic and/or suppressive therapies, which decrease the frequency or severity of opportunistic infections. Primary prophylaxis is the administration of a pharmacological agent to prevent initial infection, while secondary prophylaxis is the administration of a pharmacological agent to prevent future
occurances of infection. However, due to the effectiveness of HAARTs, there has been a significant decrease in the incidence of opportunistic infections. As a result, prophylaxis for life for HIV-related co-infections is no longer necessary in many cases. If HAART restores immune-system function as evident by a rise in CD4 counts, clinicians may stop administering primary prophylaxis under defined conditions. The advantages to ending prophylaxis are that the occurrence of opportunistic infections, which adversely affect quality of life, is no longer necessary in many cases. If a patient is acutely ill with an opportunistic infection or other complication of HIV disease, the timing of antiretroviral therapy initiation should be based on drug toxicity, ability to adhere to the treatment regimen, drug interactions, and laboratory abnormalities. However, maximally suppressive regimens should be used, and patients with advanced AIDS should not discontinue therapy during an acute opportunistic infection or malignancy unless there is drug toxicity, intolerance, or drug interactions.

Given that many studies show that baseline levels of HIV RNA may be lower and CD4 cell counts may be higher when AIDS is first diagnosed in women, federal treatment guidelines suggest that clinicians initiate HAART in women even when the CD4 cell counts are higher than 350 cells/mm³, although a specific threshold has not been established.

Recommended Antiretroviral Therapy. Since the advent of highly active antiretroviral therapy (HAART) in 1995, updated guidelines by the DHHS in July 2003 call for the use of three or more antiretroviral agents. The recommendations are for three alternative HAART regimens that sequence the medications and preserve one class of drug for future use. Currently, triple drug therapy is a first-line option in lowering VL and limiting the destruction of the immune system. Clinical trials indicate that the most effective course of treatment is by combining three or more drugs from the following three categories:

Notes: Information included in these guidelines might not represent Food and Drug Administration (FDA) approval or approved labeling for the particular products or indications in question. Specifically, the terms "safe" and "effective" might not be synonymous with the FDA-defined legal standards for product approval. The Research Institute is manufactured by Marquest, Englewood, Colorado. Letters and Roman numerals in parentheses after regimens indicate the strength of the recommendation and the quality of evidence supporting it.

Abbreviations: Anti-HBc = antibody to hepatitis B core antigen; b.i.w. = twice a week; DS = double-strength tablet; HAART = highly active antiretroviral therapy; IgG = immunoglobulin G; q.d. = daily; q.m. = monthly; q.w. = weekly; SS = single-strength tablet; t.i.w. = three times a week; and TST = tuberculin skin test.

† Prophylaxis should also be considered for persons with a CD4⁺ percentage of <14%, for persons with a history of an AIDS-defining illness, and for pregnant women with CD4⁺ counts >200 but <450/µL. TMP-SMZ also reduces the frequency of toxoplasmosis and some bacterial infections. Patients receiving dapsone should be tested for glucose-6-phosphate dehydrogenase deficiency. A dosage of 50 mg q.d. is probably less effective than that of 100 mg q.d. The efficacy of parental pentamidine (e.g., 4 mg/kg/mo) is uncertain. Fansidar (sulfadoxine-pyrimethamine) is rarely used because of severe hypersensitivity reactions. Patients who are being administered therapy for toxoplasmosis with sulfadiazine-pyrimethamine are protected against Pneumocystis carinii pneumonia and do not need additional prophylaxis against PCP.

‡ Directly observed therapy is recommended for isoniazid, 900 mg b.i.w.; isoniazid regimens should include pyridoxine to prevent peripheral neuropathy. Rifampin should not be administered concurrently with protease inhibitors or nonnucleoside reverse transcriptase inhibitors. Rifabutin should not be given with hard-gel saquinavir or delavirdine; caution is advised if the drug is coadministered with soft-gel saquinavir. Rifabutin may be administered at a reduced dose (150 mg q.d.) with indinavir, nelfinavir, or amprenavir; at a reduced dose of 150 mg q.d. (or 150 mg t.i.w.) with ritonavir; or at an increased dose (400 mg q.d.) with efavirenz; information is lacking regarding coadministration of rifabutin with nevirapine. Exposure to multidrug-resistant tuberculosis might require prophylaxis with two drugs; consult public health authorities. Possible regimens include pyrazinamide plus either ethambutol or a fluoroquinolone.

§ Protection against toxoplasmosis is provided by TMP-SMZ, by dapsone plus pyrimethamine, and possibly by atovaquone. Atovaquone may be used with or without pyrimethamine. Pyrimethamine alone probably provides little, if any, protection.

* See footnote regarding use of rifabutin with protease inhibitors or nonnucleoside reverse transcriptase inhibitors.

** Vaccination should be offered to persons who have a CD4⁺ count <200/µL, although the efficacy might be diminished. Revaccination 5 years after the first dose, or sooner if the initial immunization was given when the CD4⁺ count was <200/µL, and the CD4⁺ count has increased to >200/µL on HAART, is considered optional. Some authorities are concerned that immunizations might stimulate the replication of HIV. However, one study showed no adverse effect of pneumococcal vaccination on patient survival (McNabben et al., 1999), reference 134.

11 These immunizations or prophylactic regimens do not target pathogens traditionally classified as opportunistic but should be considered for use in HIV-infected patients as indicated. Data are inadequate concerning clinical benefit of these vaccines in this population, although it is logical to assume that these patients who develop antibody responses will derive some protection. Some authorities are concerned that immunizations might stimulate HIV replication, although for influenza vaccination, a large observational study of HIV-infected persons in clinical care showed no adverse effect of this vaccine, including multiple doses, on patient survival (I. Ward, CDC, personal communication). Hepatitis B vaccine has been recommended for all children and adolescents and for all adults with risk factors for HBV. Rimantadine and amantadine are appropriate during outbreaks of influenza A. Because of the theoretical concern that increases in HIV plasma RNA after vaccination during pregnancy might increase the risk of perinatal transmission of HIV, providers may wish to defer vaccination until after antiretroviral therapy is initiated. In addition, the risk of HIV-associated mortality and antiviral treatment against influenza, see-CDC. Prevention of hepatitis A through active or passive immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP). MMWR 1996;45(No. RR-13); CDC. Hepatitis B virus: a comprehensive strategy for eliminating transmission in the United States through universal childhood vaccination: recommendations of the Advisory Committee on Immunization Practices (ACIP). MMWR 1991;40(No. RR-13); and CDC. Prevention and control of influenza: recommendations of the Advisory Committee on Immunization Practices (ACIP). MMWR 1999;48(No. RR-4). In a few unusual occupational or other circumstances, prophylaxis should be considered; consult a specialist.

* Acyclovir is not protective against CMV. Valacyclovir is not recommended because of an unexplained trend toward increased mortality observed in persons with AIDS who were being administered this drug for prevention of CMV disease.

The NRTIs were the first class of antiretroviral agents approved for the treatment of HIV disease and included the drug known as AZT, also known as zidovudine. NRTIs limit HIV replication early in the HIV life cycle by inhibiting the enzyme reverse transcriptase, necessary for transcription of viral RNA into DNA. For many years, zidovudine was used as monotherapy, but this is no longer the accepted standard of care. NRTIs include zidovudine (AZT, ZVD, Retrovir), didanosine (ddi, Videx), zalcitabine (ddC, Hivid), stavudine (d4T, Zerit), lamivudine (3TC, Epivir), abacavir (Ziagen), tenofovir (Viread), and emtricitabine (Emtriva).\textsuperscript{67} The NRTI abacavir, in combination with ZDV and 3TC, appears to suppress VL to a similar degree when compared to a PI plus two NRTIs after 48 weeks of follow-up. However, abacavir is associated with potentially life-threatening hypersensitivity syndrome.\textsuperscript{71}

To limit the number of medications taken, thereby promoting medication adherence, a combination antiretroviral drug called Combivir, which combines two NRTIs, lamivudine 150 mg and zidovudine 300 mg, is available as a single tablet. Combivir is often taken with a PI.

The second category of antiretrovirals developed were the NNRTIs. Like the NRTIs, they function by inhibition of the enzyme reverse transcriptase. Because of the potential risk of resistance, these drugs are not recommended for monotherapy, but can be used as triple drug therapy along with an NRTI and a PI. The NNRTIs are nevirapine (Viramune), delavirdine (Rescriptor), and efavirenz (Sustiva). However, not all PIs can be given with NNRTIs; for example, saquinavir should not be given with efavirenz.

The third category of antiretrovirals are the PIs, which are highly potent with limited toxicity. PIs function by inhibiting the action of protease by binding to the cleavage site of replicating HIV and halting the production of new infectious virions. The PIs include saquinavir (Invirase, Fortovase), nelfinavir (Viracept), ritonavir (Norvir), indinavir (Crixivan), amprenavir (Agenerase), atazanavir (Reyzataz), and lopinavir/ritonavir (Kaletra).

The fourth category of antiretrovirals are the viral entry inhibitors, which inhibit the fusion of HIV-1 with CD4 T cells by binding to a region of the cell envelope that is involved with the fusion process. Enfuvirtide (Fuzeon) is the first approved viral entry inhibitor.\textsuperscript{67} A summary of the current antiretroviral medications is presented in Table 37–3.

To achieve maximal viral suppression, treatment with one potent PI and two NRTIs has proven effective in initial therapy. The NNRTI efavirenz used in combination with two NRTIs

### Nonnucleoside Reverse Transcriptase Inhibitors (NNRTIs)

<p>| Nevirapine (Viramune)                    | 200 mg, every day for 2 weeks, then 200 mg every 12 hr or 400 mg qd | Rash, pruritus, fever, thrombocytopenia, elevated liver enzymes                     | Discontinue if severe rash develops. Monitor liver function tests. Should not be used concurrently with hormonal contraception. | Decreases protease inhibitor levels (induces cytochrome P450 enzymes) |
| Delavirdine (Rescriptor)                | 400 mg tid or 600 mg bid                                      | Rash, fever, elevated liver enzymes                                                | Take on an empty stomach. Monitor liver function test. Should be taken 1 hr before or after ddI or antacids. | Increases protease inhibitors, clarithromycin, dapsone, rifabutin, ergot alkaloids, dihydropyridines, quinidine, and warfarin levels (inhibits cytochrome P450 enzymes). |
| Efavirenz (Sustiva)                     | 600 mg PO with protease inhibitor or NRTI                    | Psychiatric and nervous system symptoms such as dizziness, abnormal dreams, impaired concentration, delusions, insomnia, abnormal behavior, and rash | Taken with or without food. If taken with food, a high-fat meal should be avoided. If taken at bedtime, there is improved tolerability of nervous system side effects. | Drugs that induce CYP3A4 activity such as phenobarbital, rifampin, and rifabutin, would be expected to increase the clearance of efavirenz, therefore resulting in lower plasma concentrations. Warfarin plasma concentrations and effects are potentially increased or decreased with efavirenz. The dose of indinavir should be increased from 800 mg to 1000 mg if co-administered with efavirenz. Saquinavir and clarithromycin plasma concentrations are decreased by efavirenz. |</p>

*Source: Adapted from Murphy & Flaherty (2003), reference 67, and Porche (1999), reference 69.*
has also been shown to produce maximal viral suppression.\textsuperscript{71} The three alternative HAART regimens include:

- Triple NRTI combination
- One NNRTI (Nevirapine) plus two NRTIs
- A combination of one PI, one NNRTI, and one NRTI\textsuperscript{67}

The advantages of class-sparing regimens, such as a regimen that is PI based and NNRTI sparing, is that clinical and virological efficacy is well documented, CD$_4$-count increases are more robust than with other approaches, two steps of the viral replication process are targeted, and resistance requires multiple mutations. The disadvantages may be related to adherence and long-term side effects such as lipodystrophy, hyperlipidemia, and insulin resistance, as well as increases in cardiovascular disease and bone abnormalities (osteonecrosis, osteoporosis, and osteopenia).\textsuperscript{67} Other adverse effects associated with HAART include hepatotoxicity, hepatic steatosis, lactic acidosis, and skin rash.\textsuperscript{67} Change from one potent induction regimen to another potent regimen may be necessary if the patient's triglyceride and cholesterol levels become elevated, as lipodystrophy can be induced by protease inhibitors. Although the addition of hydroxyurea to certain antiretroviral regimens may enhance the activity of these agents, the role of hydroxyurea in HIV treatment remains uncertain given the relative lack of information from controlled trials and the number of toxicities.\textsuperscript{71}

New Treatment Strategies. In addition to the newly approved viral entry inhibitors, new treatment strategies include mega HAART, structured treatment interruptions (STI), and immune-based therapies.\textsuperscript{67} Mega-HAART has been successful in achieving viral suppression in individuals with extensive resistance to antiretroviral medications. In mega-HAART, up to 9 antiretroviral medications are administered. It is believed that no single virion is resistant to all nine drugs and, therefore, these drugs may reduce VL. However, given the drug toxicities and expense, most patients cannot tolerate this regimen for extended periods.\textsuperscript{67} Although it was believed that individuals who have a significant antiretroviral drug resistance would benefit from interruptions of all antiretroviral medications to allow for a more drug-sensitive strain of HIV-RNA to emerge, current federal guidelines do not recommend the use of STIs in individuals with advanced illness until further research can be done. This is because STI are associated with a significant increase in VL, a significant decline in CD$_4$ counts, and clinical disease progression.\textsuperscript{67} In addition, there is intense investigation of immune-based therapies such as cytokines, particularly interleukin-2, which is used in combination with antiretroviral therapies to boost the immune system and increase CD$_4$ cell counts.\textsuperscript{67}

Reasons to Change a Regimen. A change in regimen may be necessary due to insufficient viral suppression evident by an increase in VL, inadequate increase in CD$_4$ cell counts, or evidence of disease progression, as well as adverse clinical effects on the patient, or compromised adherence caused by the inconvenience of difficult regimens. However, the decision to change therapy should take into account whether other drug choices are available because another regimen may also be poorly tolerated or fail to result in better viral suppression, and such a change may limit future treatment options.\textsuperscript{67} The criteria for considering changing a patient's antiretroviral regimen include:

- Less than a 0.5 to 0.75 log$_{10}$ reduction in plasma HIV-RNA by 4 weeks after initiation of therapy or less than a 1.0 log$_{10}$ reduction in 8 weeks
- Failure to suppress plasma HIV RNA to undetectable levels within 4 to 6 months after initiating therapy
- 3-fold or greater increase from the nadir of plasma HIV-RNA not attributable to intercurrent infection, vaccination, or test methodology
- Persistent decline in CD$_4$ cell numbers measured on two separate occasions
- Clinical deterioration\textsuperscript{67}

Clinicians should consult with HIV/AIDS specialists when considering a change in regimen. Furthermore, the change in an antiretroviral regimen can be guided by drug-resistance tests, such as genotyping and phenotyping assays. Drug resistance is a major short-term risk associated with any level of viral replication.\textsuperscript{67}

Concern Regarding Drug Interactions. Considerations are also to be given to possible drug interactions such as pharmacokinetic interactions, which occur when administration of one agent changes the plasma concentration of another agent, and pharmacodynamic interactions, which occur when a drug interacts with the biologically active sites and changes the pharmacological effect of the drug without altering the plasma concentration. For example, in palliative care, drug interactions have been reported for patients who are receiving methadone for pain management and who begin therapy with an NNRTI, nevirapine. These individuals have reported symptoms of opioid withdrawal within 4 to 8 days of beginning nevirapine due to its effect on the cytochrome P-450 metabolic enzyme CYP3A4 and its induction of methadone metabolism.\textsuperscript{72} See Table 37–3 on antiretroviral medications for dosages, common side effects, special instructions, and drug interactions.

Use and Continuation of Antiretrovirals in the Hospice/Palliative Care Setting and in Patients with Organ Failure. At present, the aims of antiretroviral therapy are to prevent progression to AIDS, prevent the direct effects and symptoms of HIV disease, such as dementia, neuropathy, and diarrhea, and prevent the complications of AIDS. According to Von Gunten and colleagues,\textsuperscript{67} the continuation of antiretroviral therapy in hospice or palliative settings is often contingent on the feelings of patients regarding the therapy. Patients can be asked, “How do you feel when you take your antiretroviral medications?” Because medications may still symbolize hope, patients who
enter hospice may have a greater acceptance of their mortality and wish to stop antiretrovirals because of the side effects. Other patients may wish to continue antiretroviral therapy because of its symptom relief and the prevention of future symptoms related to opportunistic infections. Von Gunten and colleagues suggest the following plan:

1. If the drug causes burdensome symptoms, discontinue.
2. If the patient no longer wants the drug, discontinue.
3. If the patient is asymptomatic and wants the drug, continue with close clinical assessment.
4. Discontinue the measurement of VLs and CD4 counts and help the patient focus on relief of symptoms.

In the hospice and palliative care settings, it is important for clinicians to discuss with patients and families their goals of care to make important decisions regarding the appropriateness of curative, palliative, or both types of interventions. More specifically, examples of clinical decisions about palliative or disease-specific care include:

- The use of blood transfusions, psychostimulants, or corticosteroids to treat fatigue in patients with late-stage AIDS
- Aggressive antiemetic therapy for PI-induced nausea and vomiting, or discontinuation of such antiretroviral therapies, given severe side effects
- Continued suppressive therapy for CMV retinitis to prevent blindness, or use of amphotericin B for azole-resistant candidiasis for patients who wish to continue eating, or other prophylactic medications in dying patients
- Palliative treatment of disseminated MAC in patients with advanced disease who are unwilling to take anti-infectives or withdrawal of MAC or PCP prophylaxis in patients who are expected to die soon
- Use of HAART for short-term palliation of symptoms related to high VLs, or withdrawal of HAART after evident treatment failure, with assessment of medical risk-benefit and emotional value of therapy
- Decisions to initiate HAART in newly diagnosed late-stage patients

Selwyn and Rivard suggest that decisions regarding these issues need to be based on the specific goals of care, such as quality of life or life prolongation, the use of palliative care interventions to relieve the side effects of other medications, and the use of certain disease-specific therapies to enhance quality of life, as well as the decision to not prolong life when a certain threshold is met, such as progressive dementia.

The use of antiretrovirals must also be seriously considered for patients who have organ dysfunction or failure, given changes in hepatic and renal function and the effects on drug elimination. For example, patients with renal impairment may be at greater risk for zidovudine-induced hematological toxicity due to lowered production of erythropoietin.

Medication adherence is defined as the ratio of medication doses taken to those prescribed with a cutoff of 80% to categorize the patient as adherent. However, there is concern that with HAART therapy optimal viral suppression requires 90% to 95% adherence. Simplifying the patient’s HAART regimen to decrease the number of medications taken and the number of times the patient has to take medications can improve adherence.

Adherence to Therapy. Adherence, which is “the extent to which a person’s behavior coincides with medical and health advice,” is essential to health maintenance for patients with HIV/AIDS because nonadherence to antiretroviral therapy may lead not only to resistance to a whole class of drug, especially PIs, but also may affect systemic drug concentration, intracellular drug concentration, drug potency, viral resistance, and viral inhibition.

Factors not predictive of adherence include age, sex, race, education, occupation, and socioeconomic status, while factors predictive of adherence include:

- Patient characteristics, such as physical and emotional health, material resources, cultural beliefs, self-efficacy, social support, personal skills, and HIV knowledge
- Clinician factors, including interpersonal style, availability, as well as assessment, communication, and clinical skills
- Medication regimen factors, such as frequency, number, and size of pills, taste of pills, storage, side effects, effectiveness, and cost
- Illness factors, including symptoms duration, severity, and stigma

Adherence to medication regimens can be improved through educational, behavioral, and social interventions, specific to the patient, clinician, and medication regimen (Table 37–5). An established partnership and an open, trusting, and supportive relationship between patient and clinician remain key factors in promoting not only adherence to medication regimens, but support of all health-promotion and management initiatives to delay disease progression and AIDS-related complications.

### AIDS-Related Opportunistic Infections and Malignancies

Opportunistic infections are the greatest cause of morbidity and mortality in individuals with HIV disease. Given the compromised immune system of HIV-infected individuals, there is a wide spectrum of pathogens that can produce primary, life-threatening infections, particularly when the CD4 cell counts fall below 200 cells/mm³. Given the weakened immune systems of HIV-infected persons, even previously acquired infections can be reactivated. Most of these opportunistic infections are incurable and can at best be palliated to control the acute stage of infection and prevent recurrence through long-term suppressive therapy. In addition, patients with HIV/AIDS often experience concurrent or consecutive opportunistic infections that are severe and cause a great number of symptoms. In Table 37–6, the various categories of opportunistic infections and malignancies are reviewed with regard to epidemiology/pathogenesis, presentation and assessment, diagnosis, and interventions.

### Pain and Symptom Management in HIV Disease

Patients with HIV/AIDS require symptom management not only for chronic debilitating opportunistic infections and malignancies, but also for the side effects of treatments and other therapies. There are five broad principles fundamental to successful symptom management: (1) taking the symptoms seriously, (2) assessment, (3) diagnosis, (4) treatment, and (5) ongoing evaluation.

- Taking the symptoms seriously implies that symptoms often are not observable and measurable. Therefore, self-report of the patient should be taken seriously by the practitioner and acknowledged as a real experience of the patient. An important rule in symptom management is to anticipate the symptom and attempt to prevent it. Assessment and diagnosis of signs and symptoms of disease and treatment side effects requires a thorough history and physical examination. Questions as to when the symptom began and its location, duration, severity, and quality, as well as factors that exacerbate or alleviate the symptom, are important to ask. Patients can also be asked to rate the severity of a symptom by using a numerical scale from 0 to 10, with 0 being “no symptom” to 10 being “extremely severe.” Such scales can also be used to rate how much a symptom interferes with activities of daily life, with 0 meaning “no interference” and 10 meaning “extreme interference.”

- Many patients seek medical care for a specific symptom, which requires a focused history, physical exam, and diagnostic testing. Throughout the continuum of HIV disease, CD4 counts and percentages, VLs, and blood counts and chemistries may provide useful information for the management of the disease and its symptoms. Assessment of current medications and complementary therapies, including vitamin therapy, past medical illness that may be exacerbated by HIV disease, and the administration regimen of chemotherapy and radiation therapy should also be ascertained to determine the effects of treatment, side effects, adverse effects, and drug interactions. However, when treatment is no longer effective, as in the case of extremely advanced disease, practitioners must reevaluate the benefits versus burden of diagnostic testing and treatments, particularly the need for daily blood draws or more invasive and uncomfortable procedures. When the decision of the practitioners, patient, and family is that all testing and aggressive treatments are futile, their discontinuation is warranted.

- Treatment of opportunistic infections and malignancies often requires support of the patient’s immune system, antiretroviral therapy to decrease the VL and improve CD4 cell counts, and medications and therapies to cure the patient of opportunistic infections or merely palliate the associated symptoms. Indeed, the treatment of symptoms to improve quality of life plays an important role in the management of HIV disease throughout the course of the illness. In the case of many infections, acute treatment is followed by the regular dosing or maintenance therapy to prevent symptom recurrence. To maximize the quality of life, each patient’s treatment regimen and plan of care should be individualized, with documentation of the treatment response and ongoing evaluation.

- Ongoing evaluation is key to symptom management and to determining the effectiveness of traditional, experimental, and complementary therapies. Changes in therapies are often necessary because concurrent or sequential illness or conditions occur.

In an article regarding the symptom experience of patients with HIV/AIDS, Holzemer emphasizes a number of key tenets, specifically: (1) the patient is the gold standard for understanding the symptom experience; (2) patients should not be

<tr>
<td><strong>Fungal Infections</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><em>Candida albicans</em></td>
<td>Ubiquitous organism.</td>
<td>Oral <em>Candida</em> manifests as pseudomembranous white patches, easily removed, leaving erythematous or bleeding mucosa. Vaginal candidiasis manifests with pruritus and curdlike vaginal discharge. Esophageal candidiasis manifests with dysphagia. <em>Candida</em> leukoplakia cannot be removed.</td>
<td>Often presumptive by tissue inspection. Wet mount and/or potassium hydroxide (KOH) smear showing budding hyphae. Esophageal diagnosis by endoscopy with biopsy. Diagnosis by culture is unreliable.</td>
<td>Mucocutaneous infection treated locally with clotrimazole troches, nystatin suspension, fluconazole, miconazole, or amphotericin B</td>
</tr>
<tr>
<td><em>Coccidioides immitis</em> (Coccidioidomycosis)</td>
<td>Endemic to south western United States. Acquired by inhalation of spores. Occurs with CD4+ count &lt;250 µL.</td>
<td>May be asymptomatic or with progressive signs of fever, malaise, weight loss, cough, fatigue.</td>
<td>Chest radiographs may show diffuse interstitial or nodular infiltrates. Definitive diagnosis by culture or direct visualization of the organism in sputum, urine, or CSF.</td>
<td>System amphotericin B, followed by lifelong suppressive therapy with oral fluconazole</td>
</tr>
<tr>
<td><em>Cryptococcus neoformans</em> (Cryptococcosis)</td>
<td>Ubiquitous organism. Aerosolized and inhaled. Most common life-threatening infection in AIDS. <em>Cryptococcus</em> meningitis has a high mortality rate.</td>
<td>Meningitis is most common clinical manifestation, with headache, fever, stiff neck, photophobia, lethargy, and confusion. Symptoms develop over 2–4 wk. Cranial nerve palsies occur. Decreased vision can lead to blindness. Cryptococcal pneumonia may present with cough, dyspnea. Infection may disseminate to bone marrow, kidney, liver, spleen, lymph nodes, heart, oral cavity, and prostate.</td>
<td>Serum cryptococcal antigen is 99% indicative. Examination of CSF. Infection of extrameningeal sites diagnosed with India ink and culture of tissues and specimens. MRI or CT scan can show cryptococcoma. Chest radiographs show diffuse or focal infiltrates with or without mediastinal adenopathy.</td>
<td>Acute therapy with amphotericin B with or without fluconazole, then lifelong suppression with fluconazole</td>
</tr>
<tr>
<td><em>Histoplasma capsulatum</em></td>
<td>Endemic to midwest and south central United States. Spores are inhaled. Occurs with CD4+ counts &lt;100 µL.</td>
<td>Cough with fever. Often disseminated disease rather than pneumonitis. Signs and symptoms include fever, weight loss, night sweats, nausea, diarrhea, abdominal pain.</td>
<td>Chest radiographs show diffuse bilateral interstitial infiltrates. One third have normal chest radiograph; 5–10% have cutaneous lesions</td>
<td>Amphotericin B for serious illness or itraconazole or fluconazole for mild disease. Lifelong therapy of itraconazole or fluconazole</td>
</tr>

<td><strong>Mycobacterial Infections</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><em>Mycobacterium tuberculosis</em> (TB)</td>
<td>Increase in infections attributable to the high incidence of HIV infection. HIV infection may lead to reactivation of latent TB infection. Outbreaks of multidrug-resistant TB. Caused by inhalation of infectious particles that are aerosolized. Can have latent infection with no symptoms of active TB. Extrapulmonary TB may occur in 70% of HIV-infected patients; TB decreases CD4+ count and increases viral load.</td>
<td>Fever, weight loss, night sweats, and fatigue are initial complaints. With pulmonary TB, dyspnea, hemoptysis, and chest pain may occur. Extrapulmonary sites such as lymph nodes, bones, bone marrow, joints liver, spleen, skin, and CSF may show TB.</td>
<td>Positive PPD is defined as &gt;5 mm of induration at 48–72 h using Mantoux intradermal method. Check for anergy with use of mumps and <em>Candida</em>. Chest radiographs show apical or cavitary infiltrates, and may show intrathoracic adenopathy. Diagnosis confirmed by sputum for acid-fast bacilli (AFB) stain. Blood cultures for AFB should be obtained.</td>
<td>Four-drug regimen with isoniazid, rifampin, pyrazinamide, and either streptomycin or ethambutol. Prophylaxis with isoniazid or rifampin for individuals without current active TB.</td>
</tr>
<tr>
<td><em>Mycobacterium avium intracellulare</em> (MAC)</td>
<td>Composed of <em>M. avium</em> and <em>M. intracellulare</em>, two related species. Exists in water, soil, and foodstuffs. Person-to-person transmission is not likely. Most common cause of systemic bacterial infection in AIDS. Disseminated disease frequently the cause of mortality in advanced HIV disease.</td>
<td>Respiratory symptoms uncommon. MAC bacteremia is the most common syndrome. Fever, fatigue, weight loss, anorexia, nausea and vomiting, night sweats, diarrhea, abdominal pain, hepatosplenomegaly, and lymphadenopathy are common symptoms.</td>
<td>Positive cultures from normally sterile sites (e.g., blood, bone marrow, lymph nodes). Confirmed by biopsy with AFB stain. Lab studies usually demonstrate anemia and elevated alkaline phosphatase.</td>
<td>Macrolide (clarithromycin or azithromycin) and rifabutin and ethambutol for acute treatment. Prophylaxis with rifabutin or clarithromycin or azithromycin for individuals without current active TB.</td>

**Malignancies**

*Non-Hodgkin's lymphoma (NHL)*

Rate of NHL is 73 times higher in HIV-infected individuals than in the general population. Greater chance of NHL with CD4+ count <50/µL and in older white men. Caused by uncontrolled proliferation of lymphatic tissue, usually arising in the lymph nodes, spleen, liver, and bone marrow. Brain is the most common site of involvement. In patients with HIV disease, 80%—90% of the NHL is extranodal, making lymph node–based tumors uncommon.

<table>
<thead>
<tr>
<th>Nonspecific symptoms of unexplained fever, weight loss, and night sweats. Elevated serum LDH. Localizing symptoms depend on site of tumor. Neurological deficits if NHL of the brain. NHL of GI tract manifests with abdominal pain, weight loss, or GI bleeding. Small-bowel lymphoma may lead to obstructive jaundice and small-bowel intussusception.</th>
<th>Biopsy of specimens or cytological examination of tissue fluid. CT scan of brain or abdomen.</th>

<tr>
<td>Kaposi’s sarcoma (KS)</td>
<td>Classic KS is a rare, unusual neoplasm that usually affects older men of Jewish and Mediterranean ancestry; it is different from KS of HIV infection, which is most frequently seen in HIV-infected men, who have sex with men, and is the most common HIV-associated malignancy. It is associated with specific sexual practices and geographic locations.</td>
<td>Seen in any tissue but most often found in GI tract, mucous membranes, lymph nodes, and skin. Identified as patch, plaque, and/or nodular lesions of any size, color or configuration on the trunk, arms, head, or neck. Lesions in GI tract may be associated with bleeding pain, weight loss, and diarrhea.</td>
<td>GI lesions are visualized by barium studies and are best evaluated endoscopically. Histological examination of tissue biopsy to confirm the diagnosis.</td>
<td>Treatment based on immunological status and symptoms. KS lesions are highly sensitive to radiation therapy. Isolated KS lesions can be treated with cryotherapy or laser surgery. Interferon-alpha with antiretroviral agents may be beneficial, as may single agent or combination chemotherapy.</td>
</tr>
<tr>
<td>Cervical invasive cancer</td>
<td>HIV-infected women have a 7-to-10 greater chance of developing precancerous or cancerous cervical lesions and a higher rate of recurrence after cervical intraepithelial neoplasia (CIN) excisions. Progression of CIN (cervical dysplasia) to carcinoma of the cervix is slow in immunocompromised women. Incidence of AIDS-defining cervical cancer appears to be higher in women who are injecting substance users, are black, and live in the southern United States.</td>
<td>Early stages are asymptomatic and usually identified by PAP smear. Vaginal bleeding, usually postcoital, is most common symptom. Metrorrhagia and malodorous, blood-tinged vaginal discharge may be present. Advanced disease may cause pelvic, back or leg pain, hematuria, rectal bleeding, or bladder and bowel involvement.</td>
<td>PAP smear to determine the presence of abnormal cells, visible lesions, or both. Recommended that HIV-infected women have a PAP smear twice in the first year after diagnosis. If both are negative then a yearly PAP smear is recommended. If PAP smear is abnormal than a colposcopy is recommended.</td>
<td>Treatment of CIN and cervical cancer is carbon dioxide laser therapy, conization, cryosurgery, or electrocautery. Treatment of invasive cancer depends on the stage of the disease and may include surgery, radiation, or chemotherapy.</td>
</tr>
</tbody>
</table>

labeled “asymptomatic” early in the course of the infection because they often experience symptoms of anxiety, fear, and depression; (3) nurses are not necessarily good judges of patients’ symptoms, as they frequently underestimate the frequency and intensity of HIV signs and symptoms; however, following assessment, they can answer specific questions about a symptom, such as location, intensity, duration, etc.; (4) non-adherence to treatment regimens is associated with greater frequency and intensity of symptoms; (5) greater frequency and intensity of symptoms leads to lower quality of life; (6) symptoms may or may not correspond with physiological markers; and (7) patients use few self-care symptom management strategies other than medication.

**Pain Management.** Pain management must become more integrated in the comprehensive care offered to patients with AIDS because nearly two thirds of patients with HIV/AIDS report increasing pain as the disease progresses. General estimates of the prevalence of pain in HIV-infected individuals range between 25% and 80%, which is associated with psychological and functional morbidity. Shofferman and Brody reported that more than half of the patients cared for in hospice with advanced AIDS experienced pain. In a study by Breitbart and colleagues, only 8% of patients who reported severe pain (score of 8–10 on a pain intensity scale) in an AIDS-patient cohort received a strong opioid, as recommended by the World Health Organization (WHO) pain-management guidelines. Cleeland and colleagues also reported significant undermedication of pain in AIDS patients (85%), far exceeding the published reports of undertreated pain in cancer populations. In a longitudinal study of 95 patients with AIDS, Frich and Borgbjerg reported that the overall incidence of pain was 88%, and 69% suffered constant moderate to severe pain that interfered with daily living. The most common pain locations were the extremities (32%), head (24%), upper GI tract (23%) and lower GI tract (22%). Pain was associated with opportunistic infections, KS or lymphoma, as well as neuropathic pain in the extremities. The number of pain localizations increased significantly as death approached.

The inadequate assessment and treatment of pain often occurs because of societal, practitioner, and patient barriers and limitations. For example, with regard to pain management, society fears addiction to opioids and has not distinguished between the legitimate and illegal use of drugs. Practitioners may have inadequate knowledge and misconceptions about pain management, while patients often fear pain as suggesting advanced disease and are reluctant to report pain, desiring to be perceived as “good” patients.

Pain syndromes in patients with AIDS are diverse in nature and etiology. For patients with AIDS, pain can occur in more than one site, such as pain in the legs (peripheral neuropathy reported in 40% of AIDS patients), which is often associated with antiretroviral therapy such as AZT, as well as pain in the abdomen, oral cavity, esophagus, skin, perirectal area, chest, joints, muscles, and headache. Pain is also related to HIV/AIDS therapies such as antiretroviral therapies, antibacterials, chemotherapies such as vincristine, radiation, surgery, and procedures. Following a complete assessment, including a history and physical examination, an individualized pain management plan should be developed to treat the underlying cause of the pain, often arising from underlying infections associated with HIV disease.

The principles of pain management in the palliative care of patients with AIDS are the same as for patients with cancer, and include regularity of dosing, individualization of dosing, and using combinations of medications. The three-step guidelines for pain management as outlined by WHO should be used for patients with HIV disease. This approach advocates for the selection of analgesics based on the severity of pain. For mild to moderate pain, antinflammatory drugs such as NSAIDs or acetaminophen are recommended. However, the use of NSAIDs in patients with AIDS requires awareness of toxicity and adverse reactions because they are highly protein-bound, and the free fraction available is increased in AIDS patients who are cachetic or wasted. For moderate to severe pain that is persistent, opioids of increasing potency are recommended, beginning with opioids such as codeine, hydrocodone, or oxycodone (each available with or without aspirin or acetaminophen), and advancing to more potent opioids such as morphine, hydromorphone (Dilaudid), methadone (Dolophine), or fentanyl either intravenously or transdermally. In conjunction with NSAIDs and opioids, adjuvant therapies also recommended are:

- Tricyclic antidepressants, heterocyclic and noncyclic antidepressants, and serotonin reuptake inhibitors for neuropathic pain
- Psychostimulants to improve opioid analgesia and decrease sedation
- Phenothiazine to relieve anxiety or agitation
- Butyrophenones to relieve anxiety and delirium
- Antihistamines to improve opioid analgesia and relieve anxiety, insomnia, and nausea
- Corticosteroids to decrease pain associated with an inflammatory component or with bone pain
- Benzodiazepines for neuropathic pain, anxiety, and insomnia

Caution is noted, however, with use of PIs because they may interact with some analgesics. For example, ritonavir has been associated with potentially lethal interactions with meperidine, propoxyphene, and piroxicam. PIs must also be used with caution in patients receiving codeine, tricyclic antidepressants, sulindac, and indomethacin to avoid toxicity. Furthermore, for patients with HIV disease who have high fevers, the increase in body temperature may lead to increased absorption of transdermally administered fentanyl.

To insure appropriate dosing when changing the route of administration of opioids or changing from one opioid to another, the use of an equianalgesic conversion chart is suggested. As with all patients, oral medications should be used if possible, with round-the-clock dosing at regular intervals, and the use of rescue doses for breakthrough pain. Often, controlled-released morphine or oxycodone are effective drugs for patients.
with chronic pain from HIV/AIDS. In the case of neuropathic pain, often experienced with HIV/AIDS, tricyclic antidepressants such as amitriptyline, or anticonvulsants such as Neurontin can be very effective. However, the use of neuroleptics must be weighed against an increased sensitivity of AIDS patients to the extrapyramidal side effects of these drugs. If the cause of pain is increasing tumor size, radiation therapy can also be very effective in pain management by reducing tumor size, as well as the perception of pain. Tables 37–7 and 37–8 present the nonopioid analgesics for pain management in patients with AIDS and opioid analgesics for the management of mild to moderate pain and from moderate to severe pain in patients with AIDS, respectively.

Tolerance, Dependence, and Addiction. Physiological tolerance refers to the shortened or diminished effect of a drug due to exposure to the drug, and, therefore, the need for increasing doses to maintain effect. In the case of opioids, tolerance to analgesic properties of the drug appears to be uncommon in the clinical setting, while tolerance to adverse effects such as respiratory depression, somnolence, and nausea is common and favorable. Most patients can remain on stable doses of opioids for prolonged periods of time. If an increase in opioid dosage is needed, it is usually because of disease progression. Another expected physiological response to opioids is physical dependence, which occurs after 3 to 4 weeks of opioid administration, as evidenced by withdrawal symptoms after abrupt discontinuation. If a drug is to be discontinued, halving the daily dose every 1 to 2 days until the dose is equivalent to 15 mg of morphine will reduce withdrawal symptoms. Tolerance to opioids does not imply addiction, as addiction is a compulsive craving for a drug for effects other than pain relief and is extremely uncommon in patients who are terminally ill. Furthermore, studies have demonstrated that although tolerance and physical dependence commonly occur, addiction (psychological dependence) is rare and almost never occurs in individuals who do not have histories of substance abuse. However, it should be noted that a certain percentage of patients with HIV/AIDS will have a history of substance abuse, either past or current, that needs to be recognized so that their pain can be managed appropriately, as well as other symptoms for which they are self medicating. Health care providers in palliative care are often concerned with the administration of opioids to patients who have a history of substance abuse, who are in methadone maintenance programs, or who currently are abusing drugs. As a result, these patients often receive ineffective pain management. Consistent use of a standard pain scale and regular monitoring of drug consumption by one nurse and one physician can be helpful in ongoing assessment and pain management because it limits potential abuse. Oral administration of medications also lowers abuse potential. Given that substance-abusing patients have greater tolerance to morphine derivatives and benzodiazepines because of previous exposure to these drugs, increased dosage may be necessary for effective pain management, or the interval between doses should be shortened. Furthermore, the dosages of medications should be carefully monitored to avoid overdosing, given the possibility of hepatic failure in substance-abusing patients. Simultaneous use of agonists and antagonists are avoided in all populations because they provoke withdrawal symptoms.

Alleviating Opioid Side Effects. Although opioids are extremely effective in pain management for patients with HIV disease, their common side effects must be anticipated and minimized.

(continued)
In medically fragile populations, such side effects may also result from other comorbid conditions rather than from opioid analgesia itself; therefore, a complete assessment is warranted. Medications and treatments to alleviate opioid side effects include:

- Nausea and vomiting, treated with prochlorperazine (Compazine), metoclopramide (Reglan), haloperidol (Haldol), granisetron (Kytril), and ondansetron (Zofran). A change in the opioid may also be necessary.
- Constipation, treated by increasing fiber in the diet, stimulating cathartic drugs such as bisacodyl or senna, or hyperosmotic agents such as sorbitol or lactulose.
- Sedation, treated by reducing the opioid in each dose or decreasing the frequency, as well as the ingestion of caffeine, and administration of dextromethorphan or methylphenidate. Again, a change in the opioid may be warranted.
- Confusion, treated by lowering the opioid dose, changing to a different opioid or Haldol.

- Myoclonus, treated with clonazepam (Klonopin), diazepam (Valium), and baclofen (Lioresal), or a change in the opioid.
- Respiratory depression, prevented by starting at a low dose in opioid-naive patients, and being aware of relative potencies when changing opioids, as well as differences by routes of administration. Naloxone (Narcan) may be administered to reverse respiratory depression but should be used with caution in patients who are opioid tolerant because of the risk of inducing a withdrawal state. Dilute one ampule of naloxone (0.4 mg) in 10 mL of normal saline and titrate to the patient’s respirations.83

Sources: Ropka and Williams (1998), reference 13; Unzarski and Flaskeurd (1999), reference 10; Coyne et al. (2002), reference 133.

In 72 patients with AIDS, the most common symptoms were pain (97%), weakness (78%), and weight loss (53%).9 Based on a sample of 207 patients with AIDS, Holzemer and colleagues92 also found that 50% of the participants experienced shortness of breath, dry mouth, insomnia, weight loss, and headaches. The records of 50 men who died of AIDS between 1988 and 1992 indicated the distressing symptoms of dyspnea, diarrhea, confusion, dementia, difficulty eating, and swallowing. Therefore, care in the last month of life was often directed at the palliation of symptoms.21 Indeed, the last stage of HIV infection is often marked by increasing pain, GI discomfort, and depression.10 Patients may be suffering from inflammatory or infiltrative processes and somatic and visceral pain. Neuropathic pain is commonly a result of the disease process or the side effect of medications.93 Avis, Smith, and Mayer94 also reported, based on a sample of 92 HIV-positive men, that quality of life was more related to symptoms as measured by the Whalen’s HIV Symptom Index than CD4 counts or hemoglobin. With the myriad of symptoms experienced by patients with HIV disease across the illness trajectory, health care practitioners need to understand the causes, presentations, and interventions of common symptoms, as presented in Table 37–9, to enhance the quality of life of patients.

Nonpharmacological Interventions for Pain and Symptom Management. Nonpharmacological interventions for pain and symptom management can also be effective in the care of patients with HIV disease. Bed rest, simple exercise, heat or cold packs to affected sites, massage, transcutaneous electrical stimulation (TENS), and acupuncture can be effective physical therapies with this patient population. Psychological interventions to reduce pain perception and interpretation include hypnosis, relaxation, imagery, biofeedback, distraction, and patient education. In cases of refractory pain, nerve blocks and cordotomy are available neurosurgical procedures for pain management. Increasingly, epidural analgesia is an additional option that provides continuous pain relief.83

The 10 most commonly used complementary therapies and activities reported by 1106 participants in the Alternative Medical Care Outcomes in AIDS study were aerobic exercise (64%), prayer (56%), massage (54%), needle acupuncture (48%), meditation (46%), support groups (42%), visualization and imagery (34%), breathing exercises (33%), spiritual activities (33%), and other exercise (33%).95 Clearly, patients with HIV disease seek complementary therapies to treat symptoms, slow the progression of the disease, and enhance their general well-being. Nurses’ knowledge, evaluation, and recommendations regarding complementary therapies are important aspects of holistic care.

Psychosocial Issues for Patients With HIV/AIDS and Their Families

Uncertainty is a chronic and pervasive source of psychological distress for persons living with HIV disease, particularly as it relates to ambiguous symptom patterns, exacerbation and remissions of symptoms, selection of optimal treatment regimens, the complexity of treatments, and the fear of stigma and ostracism. Such uncertainty is linked with negative perceptions of quality of life and poor psychological adjustment.96 However, many practitioners focus on patient’s physical functioning and performance status as the main indicators of quality of life, rather than on the symptoms of psychological distress such as anxiety and depression.97,98 Farber and colleagues98 reported, based on a sample of 203 patients with HIV/AIDS, that positive meaning of the illness was associated with a higher level of psychological well-being and lower depressed mood, and contributed more than problem-focused coping and social support to predicting both psychological well-being and depressed mood. During the late stage of AIDS, minority women (n = 220) expressed high levels of psychological disturbance on the Psychiatric Symptom Index (PSI), which were significantly related to their mothers’ reports of having non-HIV related medical conditions, spending time in bed during the past 2 weeks, having more activity restrictions, and having difficulty caring for her child due to ill health.99 In a study of the problems and needs of HIV/AIDS patients during the last weeks of life, Butters and colleagues100 determined, based on the Support Team Assessment Schedule
(STAS), that symptom control, patient and family anxiety, spiritual needs, and communication between patient and family were their greatest needs. Furthermore, Friedland and colleagues identified the determinants of quality of life in a sample of 120 individuals with HIV/AIDS. Income, emotional support, and problem-oriented and perception-oriented coping were positively related to quality of life, while tangible support and emotion-focused coping were negatively related.

Ragsdale and Morrow emphasized the importance of focusing on the psychosocial aspects of life in patients with HIV/AIDS because patients reported a repetitive cycle of emotional changes with slight physical changes. Disfigurement, the symptoms associated with the disease and its treatment, and the contagious nature of the disease add to the psychological distress associated with HIV/AIDS.

Nurses must also be cognizant of such issues as the experience of multiple losses, complicated grieving, substance abuse, stigmatization, and homophobia, which contribute to patients’ sense of alienation, isolation, hopelessness, loneliness, and depression. Such emotional distress often extends to the patient’s family caregivers as they attempt to provide support and lessen the patient’s suffering, yet are often suffering from HIV disease themselves. Reciprocal suffering is experienced by family caregivers as well as patients, and there is the need to improve their quality of life through palliative care.

Psychosocial Assessment of Patients with HIV Disease

Psychosocial assessment of patients with HIV disease is important throughout the illness trajectory, particularly as the disease progresses and there is increased vulnerability to psychological distress. Psychosocial assessment includes the following:

- Past social, behavioral and psychiatric history, which includes the history of interpersonal relationships, education, job stability, career plans, substance use, preexisting mental illness, and individual identity
- Crisis points related to the course of the disease as anxiety, fear, and depression intensify, creating a risk of suicide
- Life-cycle phase of individuals and families, which influences goals, financial resources, skills, social roles, and the ability to confront personal mortality
- Influence of culture and ethnicity, including knowledge and beliefs associated with health, illness, dying, and death, as well as attitudes and values toward sexual behaviors, substance use, health promotion and maintenance, and health care decision-making
- Past and present patterns of coping, including problem-focused and/or emotion-focused coping
- Social support, including sources of support, types of supports perceived as needed by the patient/family, and perceived benefits and burdens of support
- Financial resources, including health care benefits, disability allowances, and the eligibility for Medicaid/Medicare

Depression and Anxiety in Patients with HIV Disease

Because AIDS is a life-threatening, chronic, debilitating illness, patients are at risk for such psychological disorders as depression and anxiety. Among persons living with HIV/AIDS, the prevalence of depression has been estimated at 10% to 25%, and is characterized by depressed mood, low energy, sleep disturbance, anhedonia, inability to concentrate, loss of libido, weight changes, and possible menstrual irregularities. It is also important to assess whether depressed patients are using alcohol, drugs, and opioids.

Patients with HIV disease who are diagnosed with depression should be treated with antidepressants that target their particular symptoms. For example, tricyclic antidepressants are indicated for anxious depression, insomnia, low daytime energy, and neuropathic pain; selective serotonin reuptake inhibitors (SSRIs) are indicated for lethargy, hopelessness, and hypersomnia; and stimulants are indicated for fatigue, hypersomnia, poor appetite, and improvement of cognitive function.

It is noted that monoamine oxidase inhibitors (MAOIs) may interact with multiple medications used to treat HIV disease and, therefore, should be avoided.

Given that depression is a common symptom in patients with HIV/AIDS, research studies have also focused on other factors that relate to depression in this patient population. Schrimshaw examined whether the source of unsupportive social interactions had differential main and interactive relations with depressive symptoms among ethnically diverse women with HIV/AIDS (n = 146). After controlling for demographic variables, it was found that unsupportive social interactions with family had a major effect in predicting more depressive symptoms, and that there was a significant interaction between unsupportive interactions from a lover/spouse and friends, which predicted high levels of depressive symptoms. Arrindell examined differential coping strategies, anxiety, depression and symptomatology among African American women with HIV/AIDS (n = 30). The results indicated that the majority of women used emotion-focused coping; however, there were no main effects for coping strategies on psychological distress and no significant difference between symptomatology and coping strategies. An inverse relationship was reported between psychological distress and social support, with less distress reported when women had financial assistance from their family and friends. There was a relationship reported between symptomatology and anxiety, with those who were asymptomatic reporting no anxiety.

Anxiety is often associated with the stresses of HIV, or may result from the medications used to treat HIV disease, such as anticonvulsants, sulfonamides, NSAIIDS, and corticosteroids. Generalized anxiety disorder is manifested as worry, trouble falling asleep, impaired concentration, psychomotor agitation, hypersensitivity, hyperarousal, and fatigue.

The treatment for patients with anxiety is based on the nature and severity of the symptoms and the coexistence of other mood disorders or substance abuse. Short-acting anxiolytics, such as lorazepam (Ativan), and alprazolam (Xanax)
are beneficial for intermittent symptoms, while buspirone (BuSpar), and clonazepam (Klonopin) are beneficial for chronic anxiety.105

For many patients experiencing psychological distress associated with HIV disease, participation in therapeutic interventions such as skills building, support groups, individual counseling, and group interventions using meditation techniques can provide a sense of psychological growth and a meaningful way of living with the disease.108–110 Such interventions are particularly helpful for patients with HIV/AIDS who may not have disclosed their sexual orientation or substance-abusing history to their families. Often, significant stress is associated with sharing such information, particularly when such disclosures occur during the stage of advanced disease. However, the need for therapeutic communication and support from all health professionals caring for the patient and their family exists throughout the illness continuum. Furthermore, fear of disclosure of the AIDS diagnosis and stigmatization in the community often raises concern in the family about the diagnosis stated on death certificates. Practitioners may therefore write a nonspecific diagnosis on the main death certificate and sign section B on the reverse side to signify to the registrar general that further information will be provided at a later date.

Often many members of a single family are infected and die because of the transmission of the disease to sexual partners and through childbirth. In the homosexual community and substance-abusing community, multiple deaths have also resulted in complicated mourning. The anxiety, depression, sadness, and loneliness associated with these multiple deaths and unending experiences of loss must be recognized and support offered. Community resources and referrals to HIV/AIDS support groups and bereavement groups are important in emotional adjustment to these profound losses.

**Spiritual Issues in AIDS**

The spiritual care of the patient and the ability of the community to support patients with HIV/AIDS may be unique opportunities for both personal and societal growth and transcendence. Mellors and colleagues 111 examined the relationship of self-transcendence and quality of life in a sample of 46 individuals with HIV/AIDS. The results demonstrated that overall self-transcendence for this sample was relatively high. Quality of life was higher than reported in previous research, yet those with disease progression, evident by the diagnosis of AIDS, had lower quality of life than those who were asymptomatic or symptomatic with CD4 counts greater than 200 cells/mm³. There was no significant difference in self-transcendence between groups, but those with AIDS were more inclined to accept death and refrained from dwelling on the past or unmet dreams. There was a moderate positive correlation between self-transcendence and quality of life.

As health professionals, assessment of patient’s spiritual needs is an important aspect of holistic care. Learning about patients’ spiritual values, needs, and religious perspectives is important in understanding their perspectives regarding their illness and their perception and meaning of life and its purpose, suffering, and eventual death. According to Elkins and colleagues,112 spirituality is a way of being or experiencing that comes about through an awareness of a transcendent dimension and identifiable life values with regard to self, others, nature, and God. An understanding of the patient’s relationship with self, others, nature, and God can inform interventions that promote spiritual well-being and the possibility of a “good death” from the patient’s perspective.

Patients living with and dying from HIV disease have the spiritual needs of meaning, value, hope, purpose, love, acceptance, reconciliation, ritual, and affirmation of a relationship with a higher being.105 Assisting patients to find meaning and value in their lives, despite adversity, often involves a recognition of past successes and their internal strengths. Respectful behavior toward patients demonstrates love and acceptance of the patient as a person. Encouraging open communication between the patient and family is important to work toward reconciliation and the completion of unfinished business.

**Case Study**

**Will Stillers, a Patient with MAC**

Will Stillers, a 28-year-old homosexual male, was admitted to the inpatient palliative care unit for fever, fatigue, anorexia, nausea and vomiting, and weight loss. He had 20 episodes of liquid diarrhea each day. As a differential diagnosis, he was tested for HIV disease. Findings indicated a CD4 count of 45 cells/mm³ and a VL of 142,000/mL, indicative of the advanced stage of HIV disease. His laboratory work indicated anemia and an elevated alkaline phosphatase. *Mycobacterium avium intracellulare* (MAC) was confirmed by biopsy with AFB stain. Physical examination revealed hepatosplenomegaly and inguinal lymphadenopathy.

Will was begun on azithromycin and rifabutin to treat MAC, as well as on a highly active antiretroviral (HAART) regimen of one potent PI and two NRTIs, specifically ritonavir (PI), and zidovudine and didanosine (ddI)(both NRTIs) to treat his advanced stage of HIV disease. Will had been estranged from his mother and sister, who lived on the West Coast. However, he had a very close friend, Carl, who viewed himself as Will’s guardian given that he had known Will for many years, and his mother was friends with Will’s mother when she lived in New York. Will lived with Carl and was considered a family member. After Will’s infection improved, he returned to Carl’s 4th-story walk-up. Will still had difficulty “holding down” food but ate small frequent meals, which he prepared for Carl and himself. Will’s only interest was in cooking because he was trained as a chef. He was very weak but enjoyed cooking as his creative outlet,
and viewed it as an opportunity to contribute to the household.

The diarrhea improved with medications, but Will was still too insecure to leave the house because he was more comfortable having immediate access to a toilet. He still felt very weak and was also concerned about his ability to climb stairs. Within the month, Will became more depressed and isolated. Although a home health aide visited for a few hours each day, there was minimal verbal interaction between them. Will began to stay in bed for long periods of time during the day. He wondered if he was ever going to recover but hoped some day to get his own apartment and be well enough to work. Will as treated with an antidepressant and within weeks his mood improved. His appetite increased and his physician was encouraged by his response to the HAART therapy. His physician discussed advance directives and Will asked Carl to be his health care proxy, as Carl knew Will’s wishes and preferences.

Over the next 2 months, Will’s quality of life improved because he was free of opportunistic infections and, although unemployed, he kept busy with household activities. Carl and Will had a wide circle of friends, but unfortunately many were also living with HIV/AIDS. Over the next 3 months, three of their friends died. Will understood the fragility of his condition and was adherent to his medication regimen. However, night sweats, fever, and diarrhea returned, and he was readmitted to the hospital within 6 months of his initial hospitalization with an exacerbation of MAC and severe dehydration. The palliative care team was asked for a consultation by the AIDS specialist. The advanced practice nurse developed a very supportive relationship with Will and Carl. She listened attentively to his fears and concerns and provided a caring presence that helped him to relax. They discussed his relationship with his mother and sister, and he asked the nurse to call his sister and tell her about his hospitalization. Will was coming to terms with his diagnosis and was ready to move beyond old hurts in his relationship with his family. Although he did not have a strong religious faith, Will asked for the chaplain to visit because he was trying to come to terms with his own suffering and the death of his friends.

Over the next few weeks, Will’s infection began to resolve, and the advanced practice nurse promised him that when he felt better, she would bring him a meal from his favorite “soul food” restaurant where he once worked. Will’s sister and mother asked to come to see him. On the day they arrived, Will’s condition took an unexpected turn for the worse. With Carl and his family at his side, Will’s fever began to rise and he became delirious. Several tests were conducted to identify other potential sources of the infection, and other possible reasons for the delirium. His symptoms were treated with Haldol and antipyretics. However, within the next day, Will slipped into a coma and died. In a letter found at his bedside, Will thanked his physicians and the members of the palliative team for their care. He said that without their support, he never would have reconciled with his mother and sister. He knew that his illness was advanced and did not expect to regain his health. He thanked Carl for his unconditional friendship and care. He said “I feel that you are my older brother whom I could always count on—no matter what.” Members of the palliative care team were surprised at his sudden death but also understood the uncertainty of living with advanced AIDS. In a celebration of his life, the palliative care team brought Will’s favorite foods from the restaurant where he worked, and asked Will’s family to join them to celebrate his loving spirit and his life. In remembrance, tears were shed because of the tragic death of this promising young man who had touched their hearts, yet the importance of unconditional love, caring presence, and the joys of everyday life, such as sharing a meal, were reinforced by the message he left.

As with many life-threatening illnesses, patients with AIDS may express anger with God. Some may view their illness as a punishment or are angry that God is not answering their prayers. Expression of feelings can be a source of spiritual healing. Clergy can also serve as valuable members of the palliative care team in offering spiritual support and alleviating spiritual distress. The use of meditation, music, imagery, poetry, and drawing may offer outlets for spiritual expression and promote a sense of harmony and peace.

In a grounded-theory study of hope in patients with HIV/AIDS, Kylma and colleagues found that patients had an alternating balance between hope, despair, and hopelessness based on the possibilities of daily life. They experienced losses such as loss of joy, carefree time, safety, self-respect, potential parenthood, privacy, and trust in self, others, systems, and God. However, there was hope as they received strength by seeing their life from a new perspective, and an acceptance of the uncertainty of life and the value of life. Hope was described as a basic resource in life and meant the belief that life is worth living at the present and in the future, with good things still to come. Despair meant losing grip, unable to take hold of anything, while hopelessness implied giving up in the face of an assumably nonexistent future, which was the opposite of hope.

For all patients with chronic, life-threatening illness, hope often shifts from hope that a cure will soon be found to hope for a peaceful death with dignity, including the alleviation of pain and suffering, determining one’s own choices, being in the company of family and significant others, and knowing that their end-of-life wishes will be honored. Often, the greatest spiritual comfort offered by caregivers or family for patients comes from active listening and meaningful presence by sitting and holding their hands and knowing that they are not abandoned and alone.

Spiritual healing may also come from life review, as patients are offered an opportunity to reminisce about their lives, reflect on their accomplishments, reflect on their misgivings, and forgive themselves and others for their imperfections. Indeed, such spiritual care conveys that even in the shadow of death, there can be discovery, insight, the completion of relationships, the experience of love of self and others, and the transcendence
of emotional and spiritual pain. Often, patients with AIDS, by their example, teach nurses, family, and others how to transcend suffering and how to die with grace and dignity.

**Advanced Care Planning**

Advanced planning is another important issue related to end-of-life care for patients with HIV/AIDS. Most patients with AIDS have not discussed with their physicians the kind of care they want at the end of life, although more gay men have executed an advance directive than injection-drug users or women. Nonwhite patients with AIDS report that they do not like to talk about the care they would want if they were very sick, and are more likely to feel that if they talk about death, it will bring death closer. In contrast, white patients were more likely to believe that their doctor was an HIV/AIDS expert and good at talking about end-of-life care, and recognize they have been very sick in the past, and that such discussions are important. According to Ferris and colleagues, health care providers can assist patients and families by (1) discussing the benefits of health care and social support programs, unemployment insurance, worker’s compensation, pension plans, insurance, and union or association benefits; (2) emphasizing the importance of organizing information and documents so that they are easily located and accessible; (3) suggesting that financial matters be in order, such as power of attorney or bank accounts, credit cards, property, legal claims, and income tax preparation; (4) discussing advance directives or power of attorney for care and treatment, as well as decisions related to the chosen setting for dying; and (5) discussing the patient’s wishes regarding their death—Whom does the patient want at the bedside? What rituals are important to the dying patient? Does the patient wish an autopsy? What arrangements does the patient want regarding the funeral services and burial? Where should donations in remembrance be sent? It is important to realize that these issues should be discussed at relevant stages in the person’s illness, in a manner that is both respectful to the patient’s wishes and strengths and that promotes the patient’s sense of control over his or her life and death.

Health care providers must also understand the concept of competency, a “state in which the person is capable of taking legal acts, consenting or refusing treatment, writing a will or power of attorney.” In assessing the patient’s competency, the health provider must question whether the decision maker knows the nature and effect of the decision to be made and understands the consequences of his or her actions, and determine if the decision is consistent with an individual’s life history, lifestyle, previous actions, and best interests.

When an individual is competent, and in anticipation of the future loss of competency, he or she may initiate advance directives such as a living will and/or the designation of a health care proxy, who will carry out the patient’s health care wishes or make health care decisions in the event that the patient becomes incompetent. The patient may also give an individual the power of attorney regarding financial matters and care or treatment issues. Advance directives include the patient’s decisions regarding such life-sustaining treatments as cardiopulmonary resuscitation, use of vasoactive drips to sustain blood pressure and heart rate, dialysis, artificial nutrition and hydration, and the initiation or withdrawal of ventilatory support. The signing of advance directives must be witnessed by two individuals who are not related to the patient or involved in the patient’s treatment. Individuals who are mentally competent can revoke at any time their advance directives. If a patient is deemed mentally incompetent, state statutes may allow the court to designate a surrogate decision-maker for the patient.

**Palliative Care Through the Dying Trajectory**

Death from AIDS is usually due to multiple causes, including chronic infections, malignancies, neurological disease, malnutrition, and multisystem failure. However, even for patients with HIV/AIDS for whom death appears to be imminent, spontaneous recovery with survival of several more weeks or months is possible. The terminal stage is often marked by periods of increasing weight loss and deteriorating physical and cognitive functioning. The general rule related to mortality is that the greater the cumulative number of opportunistic infections, illnesses, complications, and/or deviance of serological or immunological markers in terms of norms, the less the survival time. Survival time is also decreased by psychosocial factors such as a decrease in physical and emotional support as demands increase for the caregivers, feelings of hopelessness by the patient, and older age (>39 years). In the terminal stage of HIV disease, decisions related to prevention, diagnosis, and treatment pose ethical and clinical issues for both patients and their health care providers because they must decide on the value and frequency of laboratory monitoring, use of invasive procedures, use of antiretroviral and prophylactic measures, and patients’ participation in clinical trials.

The dying process for patients with advanced AIDS is commonly marked by increasingly severe physical deterioration, leaving the patient bedbound, experiencing wasting, dyspnea at rest, and pressure ulcers. Ultimately, patients become dependent on others for care. Febrile states and changes in mental status often occur as death becomes more imminent. Maintaining the comfort and dignity of the patients becomes a nursing priority. Symptomatic treatments, including pain management, should be continued throughout the dying process, since even obtunded patients may feel pain and other symptoms.

The end of life is an important time for individuals to accept their own shortcomings and limitations and differences with significant others so that death may be accepted without physical, psychosocial, and spiritual anguish. At the end of life, patients with AIDS may have a desire for hastened death. Pessin, based on a sample of 128 terminally ill patients with
Loss, Grief, and Bereavement for Persons with HIV/AIDS and Their Survivors

Throughout the illness trajectory, patients with HIV disease experience many losses: a sense of loss of identity as they assume the identity of a patient with AIDS; loss of control over health and function; loss of roles as the illness progresses; loss of body image due to skin lesions, changes in weight, and wasting; loss of sexual freedom because of the need to change sexual behaviors to maintain health and prevent transmission to others; loss of financial security through possible discrimination and increasing physical disability; and loss of relationships through possible abandonment, self-induced isolation, and the multiple deaths of others from the disease. In a study of AIDS-related grief and coping with loss among HIV-positive men and women (n = 268), Sikkema and colleagues reported that the severity of grief reaction to AIDS-related losses was associated with escape-avoidance and self-controlling coping strategies, the type of loss, depressive symptoms, and history of injection drug use. For health care professionals, each occurrence of illness may pose new losses and heighten the patient’s awareness of his or her mortality. Each illness experience is therefore an opportunity for health professionals to respond to cues of the patients in addressing their concerns and approaching the subject of loss, dying, and death. Given that grief is the emotional response to loss, patients dying from AIDS may also manifest the signs of grief, which include feelings of sadness, anger, self-reproach, anxiety, loneliness, fatigue, shock, yearning, relief, and numbness; physical sensations such as hollowness in the stomach, tightness in the chest, oversensitivity to noise, dry mouth, muscle weakness, and loss of coordination; cognitions of disbelief, confusion; and behavioral disturbances in appetite, sleep, social withdrawal, loss of interest in activities, and restless overactivity.

Upon the death of the patient, the patient’s family and significant others enter a state of bereavement, or a state of having suffered a loss, which is often a long-term process of adapting to life without the deceased. Family and significant others may experience signs of grief, including a sense of presence of the deceased, paranormal experiences or hallucinations, dreams of the deceased, a desire to have cherished objects of the deceased, and to visit places frequented by the deceased. The work of grief is a dynamic process that is not time-limited and predictable. It may be that those left behind never “get over” the loss but, rather, find a place for it in their life and create through memory a new relationship with their loved one.

Families and partners of patients with AIDS may experience disenfranchised grief, defined as the grief that persons experience when they incur a loss that is not openly acknowledged, publicly mourned, or socially supported. Support is not only important in assisting families in the tasks of grieving, but is also important for nurses who have established valued relationships with their patients. Indeed, disenfranchised grief may also be experienced by nurses who do not allow themselves to acknowledge their patient’s death as a personal loss, or who are not acknowledged by others, such as the patient’s family or even professional colleagues, for having suffered a loss.

For all individuals who have experienced a loss, Worden has identified the tasks of grieving as (1) accepting the reality of the death; (2) experiencing the pain of grief; (3) adjusting to a changed physical, emotional, and social environment in which the deceased is missing; and (4) finding an appropriate emotional place for the person who died in the emotional life of the bereaved.
To facilitate each of Worden’s tasks, Mallinson recommends the following nursing interventions:

- Accept the reality of death by speaking of the loss and facilitating emotional expression.
- Work through the pain of grief by exploring the meaning of the grief experience.
- Adjust to the environment without the deceased by acknowledging anniversaries and the experience of loss during holidays and birthdays; help the bereaved to problem solve and recognize their own abilities to conduct their daily lives.
- Emotionally relocate the deceased and move on with life by encouraging socialization through formal and informal avenues.

The complications of AIDS-related grief often come from the secrecy and social stigma associated with the disease. Reluctance to contact family and friends can restrict the normal support systems available for the bereaved.

In addition to a possible lack of social support, the death of patients with AIDS may result in complicated grief for the bereaved, given that death occurs after lengthy illness, and the relationships may have been ambivalent. Through truthful and culturally sensitive communication, health professionals can offer families support in their grief and promote trust that their needs are understood and validated. Further bereavement and related nursing interventions are discussed in Chapter 27.

Conclusion

The care of patients with HIV/AIDS requires both active treatment and palliative care throughout the disease trajectory to relieve the suffering associated with opportunistic infections and malignancies. With up-to-date knowledge regarding HIV disease, including changes in epidemiology, diagnostic testing, treatment options, and available resources, nurses can offer effective and compassionate care to patients, alleviating physical, emotional, social, and spiritual suffering at all stages of HIV disease. Patients can maintain a sense of control and dignity until death by establishing a partnership with their health care professionals in planning and implementing their health care, as well as through advanced care planning to insure that their end-of-life preferences and wishes are honored. The control of pain and symptoms associated with HIV/AIDS enables the patient and family to expend their energies on spiritual and emotional healing, and the possibility for personal growth and transcendence even as death approaches. Palliative care offers a comprehensive approach to address the physical, emotional, social, and spiritual needs of individuals with incurable progressive illness throughout the illness trajectory until death. Palliative care therefore preserves patients’ quality of life by protecting their self-integrity, reducing a perceived helplessness, and lessening the threat of exhaustion of coping resources. Through effective and compassionate nursing care, patients with AIDS can achieve a sense of inner well-being even at death, with the potential to make the transition from life as profound, intimate, and precious an experience as their birth.

Caring for the Drug-Addicted Patient at the End of Life

Thank you for doctoring my brother. No one else would take care of him.—Brother of a dying cancer patient who had a comorbid addiction problem, requiring extensive management and unorthodox doses of opioid analgesics. At the end of life, the patient was able to go hunting and spend quality time with his family.

Substance use disorders are a consistent phenomenon in the United States, with estimated base rates of 6% and 15%.1–4 This prevalence of drug abuse certainly touches medically ill patients and can negatively influence how pain is treated. Because of these issues and despite the fact that national guidelines exist for the treatment of pain disorders such as cancer, pain continues to be undertreated, even at the end of life.5–7 In cancer, approximately 40% to 50% of patients with metastatic disease and 90% of patients with terminal cancer or other advanced diseases are reported to experience unrelieved pain.5–7 Furthermore, inadequate treatment of cancer pain is an even greater possibility if the patient is a member of an ethnic minority, female, elderly, a child, or a substance abuser.8 Thus, for multicultural patients, we sometimes have conflicting multiple biases in pain treatment that can lead to poor management, mutual suspicion and alienation, and suffering unless these biases are adequately addressed.

Incidence of Substance Use Disorders in Patients with Advanced Disease

Although few studies have been conducted to evaluate the epidemiology of substance abuse in patients with advanced illness, substance use disorders appear to be relatively rare within the tertiary-care population with cancer and other advanced diseases. Findings from a consultations review performed by the Psychiatry Services at Memorial Sloan-Kettering Cancer Center revealed that requests for management of issues related to substance abuse consisted of only 3% of the consultations.9,10

While the incidence of substance use disorders is much lower in patients with advanced disease than in society at large, in community-based medical populations, and emergency medical departments, this may not represent the true prevalence in the advanced illness spectrum overall. Institutional biases or a tendency for patients’ underreporting in
tertiary-care hospitals may be reflective of the relatively low prevalence of substance abuse among advanced patients. Social forces may also inhibit patients’ reporting of drug use behavior. Many drug abusers are of lower socioeconomic standing and feel alienated from the healthcare system, and, therefore, may not seek care in tertiary-care centers. Furthermore, those who are treated in these centers may not acknowledge drug abuse for fear of stigmatization. Additionally, minority patients are treated in such settings more often than are Caucasians.

Issues in Defining Abuse and Addiction in the Medically Ill

It is difficult to define substance abuse and addiction in patients with advanced illness, since the definitions of both terms have been adopted from addicted populations without medical illness. Furthermore, the pharmacological phenomena of tolerance and physical dependence are commonly confused with abuse and addiction. The use of these terms is so strongly influenced by sociocultural considerations that it may lead to confusion in the clinical setting. Therefore, the clarification of this terminology is necessary to improve the diagnosis and management of substance abuse when treating patients with advanced disease.

Substance abuse concentrates on the psychosocial, physical, and vocational harm that occurs from drug-taking, which makes identifying drug-taking behaviors more difficult in patients with advanced illness who are receiving potentially abusable drugs for legitimate medical purposes. In contrast, substance dependence emphasizes chronicity, and includes the dimensions of tolerance and physical dependence. Due to the possibility that patients may develop these effects due to therapeutic drug use, it is inapplicable to use this terminology in the medically ill. Not only does the existing nomenclature complicate the effort to distinguish the drug-taking behaviors of patients with advanced disease that are appropriately treated with potentially abusable drugs, it also impedes the communication that is fundamental for proper pain management and medical care.

Theoretical Problems in the Diagnosis of Substance Use Disorders

Since substance abuse is increasingly widespread in the population at large, patients with advanced disease who have used illicit drugs are more frequently encountered in medical settings. Illicit drug use, actual or suspected misuse of prescribed medication, or actual substance use disorders create the most serious difficulties in the clinical setting, complicating the treatment of pain management. However, the management of substance abuse is fundamental to adherence to medical therapy and safety during treatment. Also, adverse interactions between illicit drugs and medications prescribed as part of the patient’s treatment can be dangerous. Continuous substance abuse may alienate or weaken an already tenuous social support network that is crucial for alleviating the chronic stressors associated with advanced disease and its treatment. Therefore, a history of substance abuse can impede treatment and pain management and increase the risk of hastening morbidity and mortality among advanced patients, which can only be alleviated by a therapeutic approach that addresses drug-taking behavior while expediting the treatment of the malignancy and distressing symptoms, as well as addiction.

When assessing drug-taking behaviors in the patient with advanced disease, issues exist that increase the difficulty in arriving at a diagnosis of abuse or addiction. These issues include the problem of undertreatment of pain, sociocultural influences on the definition of aberrancy in drug-taking, and the importance of cancer-related variables.

Pseudoaddiction

Various studies provide compelling evidence that pain is undertreated in populations with advanced disease. Clinical experience indicates that the inadequate management of symptoms and related pain may be the motivation for aberrant drug-taking behaviors. Pseudoaddiction is the term used to depict the distress and drug-seeking that can occur in the context of unrelieved pain, such as similar behaviors in addicts. The main factor of this syndrome is that sufficient pain relief eliminates aberrant behaviors.

The potential for pseudoaddiction creates a challenge for the assessment of a known substance abuser with an advanced illness. Clinical evidence indicates that aberrant behaviors impelled by unrelieved pain can become so dramatic in this population that some patients appear to return to illicit drug use as a means of self-medication. Others use more covert patterns of behavior, which may also cause concerns regarding the possibility of true addiction. While it may not be obvious that drug-related behaviors are aberrant, the meaning of these behaviors may be difficult to discern in the context of unrelieved symptoms.

Distinguishing Aberrant Drug-Taking Behaviors

Whereas abuse is defined as the use of an illicit drug or a prescription drug without medical indication, addiction refers to the continued use of either type of drug in a compulsive manner regardless of harm to the user or others. However, when a drug is prescribed for a medically diagnosed purpose, less assuredness exists as to the behaviors that could be deemed aberrant, thereby increasing the potential for a diagnosis of drug abuse or addiction. Although it is difficult to disagree with the aberrancy of certain behaviors, such as intravenous injection of oral formulations, various other behaviors are less blatant, such as a patient experiencing unrelieved pain who is taking an extra dose of prescribed opioids.
The ability to categorize these questionable behaviors as apart from social or cultural norms is also based on the assumption that certain parameters of normative behavior exist. Although it is useful to consider the degree of aberrancy of a given behavior, it is important to recognize that these behaviors exist along a continuum, with certain behaviors being less aberrant (such as aggressively requesting medication) and other behaviors being more aberrant (such as injection of oral formulations). Empirical data defining these parameters does not exist regarding prescription drug use (Table 38–1). If a large portion of patients were found to engage in a certain behavior, it may be normative, and judgments regarding aberrancy should be influenced accordingly.9,10

The importance of social and cultural norms also raises the possibility of bias in the determination of aberrancy. A clinician’s willingness to classify a questionable drug-related behavior as aberrant when performed by a member of a certain social or ethnic group may be influenced by bias against that group. Based on clinical observation, this type of prejudice has been found to be common in the assessment of drug-related behaviors of patients with substance abuse histories. Regardless if the drug-abuse history was in the past or present, questionable behaviors by these patients may immediately be labeled as abuse or addiction. The possibility of bias in the assessment of drug-related behaviors also exists for patients who are members of racial or ethnic minority groups different from that of the clinician.9,10 The following case study illustrates the point that aberrant behaviors do not have a universal interpretation (including the illegal and obviously worrisome ones) and must be understood in the context of the patient’s care.

**CASE STUDY**

**A 40-Year-Old Woman with Thymoma and Borderline Personality Disorder**

A 40-year-old woman with thymoma and borderline personality disorder, chronic pain, and anxiety was angry and feared abandonment by her psycho-oncologist while he was on vacation. Her covering physician gave her a prescription of 80 alprazolam tablets on the Friday before the Monday of the psycho-oncologist’s expected return. The patient impulsively altered the prescription so that, instead of reading “80 tablets,” it read “180 tablets.” The alteration was detected by a pharmacist, who reported it back to her medical team. In the context of the patient’s previously uneventful use of the medicine, her psychiatric diagnosis, and the therapist’s vacation, it was agreed that the patient’s behavior represented an expression of the psychodynamics of abandonment and a self-defeating expression of rage at the therapist. It was dealt with in detail in her psychotherapy.

**Disease-Related Variables**

Changes caused by progressive diseases, such as cancer, also challenge the principal concepts used to define addiction. Alterations in physical and psychosocial functioning caused by advanced illness and its treatment may be difficult to distinguish from the morbidity associated with drug abuse. In particular, alterations in functioning may complicate the ability to evaluate a concept that is vital to the diagnosis of addiction: “use despite harm.” For example, discerning the questionable behaviors can be difficult in a patient who develops social withdrawal or cognitive changes after brain irradiation for metastases. Even if diminished cognition is clearly related to pain medication used in treatment, this effect might only reflect a narrow therapeutic window rather than the patient’s use of analgesic to acquire these psychic effects.9,10

To accurately assess drug-related behaviors in patients with advanced disease, explicit information is usually required regarding the role of the drug in the patient’s life. Therefore, the presence of mild mental clouding or the time spent out of bed may have less meaning than other outcomes, such as non-compliance with primary therapy related to drug use, or behaviors that threaten relationships with physicians, other health care professionals, and family members.9,10

**Appropriate Definitions of Abuse and Addiction for Advanced Illness**

A more appropriate definition of addiction would exemplify that it is a chronic disorder characterized by “the compulsive use of a substance resulting in physical, psychological, or social harm to the user and continued use despite the harm.”13 Although this definition is not without fault, it emphasizes
that addiction is essentially a psychological and behavioral syndrome.9,10
A differential diagnosis should also be considered if questionable behaviors occur during pain treatment. A true addiction (substance dependence) is only one of many possible interpretations. A diagnosis of pseudoaddiction should also be taken into account if the patient is reporting distress associated with unrelieved symptoms. Impulsive drug use may also be indicative of another psychiatric disorder, diagnosis of which may have therapeutic implications. On occasion, aberrant drug-related behaviors appear to be causally remotely related to a mild encephalopathy, with perplexity concerning the appropriate therapeutic regimen. On rare occasions, questionable behaviors imply criminal intent. These diagnoses are not mutually exclusive.9,10
Varied and repeated observations over a period of time may be necessary to categorize questionable behaviors properly. Perceptual psychiatric assessment is crucial and may require evaluation by consultants who can elucidate the complex interactions among personality factors and psychiatric illness. Some patients may be self-medicating symptoms of anxiety, depression, insomnia, or problems of adjustment (such as boredom due to decreased ability to engage in usual activities and hobbies). Yet others may have character pathology that may be the more prominent determinant of drug-taking behavior. Patients with borderline personality disorders, for example, may impulsively use prescription medications that regulate inner tension or improve chronic emptiness or boredom and express anger at physicians, friends, or family. Psychiatric assessment is vitally important for both the population without a prior history of substance abuse and the population of known substance abusers who have a high incidence of psychiatric comorbidity.14

Cultural Issues in the Treatment of Substance Use Disorders
As noted earlier, cancer pain continues to be grossly under-treated despite the availability of guidelines for its clinical management, with patients who are members of an ethnic minority or substance abusers having a greater risk of inadequate treatment of cancer pain.15–17 In fact, various studies have documented that minority patients that receive insufficient pain treatment when compared to nonminority patients when being treated for pain caused by a variety of sources.15–17 Since minority patients with advanced illness are undertreated for pain, they may be at greater risk of being misdiagnosed if exhibiting behaviors of pseudoaddiction.

Recently, more attention has been given to the significant influence that age, gender, and ethnicity have on the issues and treatment of substance abuse. Certain issues must be considered when implementing substance abuse treatment with the minority patient who is suspected of having a substance use disorder.18

First and foremost, it must be recognized that immense diversity exists within the different sociocultural groups themselves. Any given minority patient may possess beliefs, values, or drug-taking behaviors that greatly differ from the majority of the sociocultural group of which the patient is a member. In addition to ethnic orientation, attention must also focus on other sociocultural factors such as age, gender, sexual orientation, income, education, geographic location, and level of acculturation.18 Ascribing certain cultural characteristics to all patients of a particular minority group may lead to stereotyping, alienating patients, and compromising treatment effectiveness.19 While the perfect scenario would be to accurately understand all of the possible cultural issues that influence the patient within the context of his or her life circumstances, this is difficult and may be impractical.1,18 Therefore, it is particularly important to respond to cultural needs in the treatment of substance abuse, because sociocultural factors greatly affect the manifestation of the disease. Consequently, clinicians must often acculturate their therapeutic approaches to accommodate the patient’s sociocultural orientation.18

Risks in Patients with Current or Remote Histories of Drug Abuse
There is a lack of information regarding the risk of abuse or addiction during or subsequent to the therapeutic administration of potentially abusable drugs to medically ill patients with a current or remote history of abuse or addiction.9 The possibility of successful long-term opioid therapy in patients with cancer or chronic nonmalignant pain has been indicated by anecdotal reports, particularly if the abuse or addiction is remote.20–22 Since it is commonly accepted that the likelihood of aberrant drug-related behavior occurring during treatment for medical illness will be greater for those with a remote or current history of substance abuse, it is reasonable to consider the possibility of abuse behaviors occurring when using different therapies. For example, while no clinical evidence exists to

support that the use of short-acting drugs or the parenteral route is more likely to cause questionable drug-related behaviors than other therapeutic strategies, it may be prudent to avoid such therapies in patients with histories of drug abuse. A basic set of principles pertaining to prescribing controlled substances to this patient population is presented in Table 38-2.

Summary of Issues

Clinicians should understand that essentially any drug that acts upon the central nervous system or any route of administration has the potential to be abused. Therefore, a more comprehensive approach that recognizes the biological, chemical, social, and psychiatric aspects is necessary to effectively manage patients with substance abuse histories. Using this strategy extends beyond merely avoiding certain drugs or routes of administration—it also affords practical means to manage risk during cancer treatment.

Clinical Management of Advanced-Disease Patients with Substance Use Histories

The most challenging issues in caring for patients with advanced disease typically arise from patients who are actively abusing alcohol or other drugs. This is because patients who are actively abusing drugs experience more difficulty in managing pain. Patients may become caught in a cycle where pain functions as a barrier to seeking treatment for addiction with another addiction, possibly complicating treatment for chronic pain. Also, since pain is undertreated, the risk of binging with prescription medications and other substances increases for drug-abusing patients.

General Guidelines

The following guidelines can be beneficial, whether the patient is actively abusing drugs or has a history of substance abuse. The principles outlined assist clinicians in establishing structure, control, and monitoring of addiction-related behaviors, which may be helpful and necessary at times in all pain treatment.

Recommendations for the long-term administration of potentially abusable drugs, such as opioids, to patients with a history of substance abuse are based exclusively on clinical experience. Research is needed to ascertain the most effective strategies and to empirically identify patient subgroups who may be most responsive to different approaches. The following guidelines broadly reflect the types of interventions that might be considered in this clinical context.

Multidisciplinary Approach

Pain and symptom management is often complicated by various medical, psychosocial, and administrative issues in the population of advanced patients with a substance use disorder. The most effective team may include a physician with expertise in pain/palliative care, nurses, social workers, and, when possible, a mental health care provider with expertise in the area of addiction medicine.

Assessment of Substance Use History

In an effort to not offend, threaten, or anger patients, clinicians many times avoid asking patients about drug abuse. There is also often the expectation that patients will not answer truthfully. However, obtaining a detailed history of duration, frequency, and desired effect of drug use is vital. Adopting a nonjudgmental position and communicating in an empathetic and truthful manner is the best strategy when taking patients’ substance abuse histories.

In anticipating defensiveness on the part of the patient, it can be helpful for clinicians to mention that patients often misrepresent their drug use for logical reasons, such as stigmatization, mistrust of the interviewer, or concerns regarding fears of undertreatment. It is also wise for clinicians to explain that in an effort to keep the patient as comfortable as possible, by preventing withdrawal states and prescribing sufficient medication for pain and symptom control, an accurate account of drug use is necessary.

The use of a careful, graduated-style interview can be beneficial in slowly introducing the assessment of drug abuse. This approach begins with broad and general inquiries regarding the role of drugs in the patient’s life, such as caffeine and nicotine, and gradually proceeds to more specific questions regarding illicit drugs. This interview style can also assist in discerning any coexisting psychiatric disorders, which can significantly contribute to aberrant drug-taking behavior. Once identified, treatment of comorbid psychiatric disorders can greatly enhance management strategies and decrease the risk of relapse.

Setting Realistic Goals for Therapy

The rate of recurrence for drug abuse and addiction is high. The stress associated with advanced illness and the easy availability of centrally acting drugs increases this risk. Therefore, total prevention of relapse may be impossible in this type of setting. Gaining an understanding that compliance and abstinence are not realistic goals may decrease conflicts with staff members in terms of management goals. Instead, the goals might be perceived as the creation of a structure for therapy that includes ample social/emotional support and limit-setting to control the harm done by relapse.

There may be some subgroups of patients who are unable to comply with the requirements of therapy due to severe substance use disorders and comorbid psychiatric diagnoses. In these instances, clinicians must modify limits on various occasions and endeavor to develop a greater variety and intensity of supports. This may necessitate frequent team meetings and consultations with other clinicians. However, pertinent expectations must be clarified and therapy that is not successful should be modified.
Evaluation and Treatment of Comorbid Psychiatric Disorders

Extremely high comorbidity of personality disorders, depression, and anxiety disorders exist in alcoholics and other patients with substance abuse histories. The treatment of depression and anxiety can increase patient comfort and decrease the risk of relapse or aberrant drug-taking.

Preventing or Minimizing Withdrawal Symptoms

Since many patients with drug abuse histories use multiple drugs, it is necessary to conduct a complete drug-use history to prepare for the possibility of withdrawal. Delayed abstinence syndromes, such as may occur after abuse of some benzodiazepine drugs, may be particularly diagnostically challenging.

Considering the Therapeutic Impact of Tolerance

Patients who are active substance abusers may be tolerant to drugs administered for therapy, which will make pain management more difficult. The magnitude of this tolerance is never known. Therefore, it is best to begin with a conservative dose of therapeutic drug and then rapidly titrate the dose, with frequent reassessments until the patient is comfortable.

Applying Pharmacological Principles to Treating Pain

Widely accepted guidelines for cancer pain management must be used to optimize long-term opioid therapy. These guidelines stress the importance of patient self-report as the base for dosing, individualization of therapy to identify a favorable equilibrium between efficacy and side effects, and the value of monitoring over time. They also are strongly indicative of the concurrent treatment of side effects as the basis for enhancing the balance between both analgesia and adverse effects.

Individualization of the dose without regard to the size, which is the most important guideline for long-term opioid therapy, can be difficult in populations with substance abuse histories. Although it may be appropriate to use care in prescribing potentially abusable drugs to these populations, deciding to forego the guideline of dose individualization without regard to absolute dose may increase the risk of undertreatment. Aberrant drug-related behaviors may develop in response to unrelieved pain. Although these behaviors might be best understood as pseudoadduction, the incidence of such behaviors serves to verify clinicians’ fears and encourages greater prudence in prescribing.

Another common misconception is the use of methadone. Clinicians who manage patients with substance abuse histories must comprehend the pharmacology of methadone due to its dual role as a treatment for opioid addiction and as an analgesic. Methadone impedes withdrawal for significantly longer periods than it relieves pain. That is, abstinence can be prevented and opioid cravings lessened with a single dose, while most patients appear to require a minimum of three doses daily to obtain sustained analgesia. Although patients who are receiving methadone maintenance for treatment for opioid addiction can be administered methadone as an analgesic beyond the guidelines of the addiction treatment program, this usually necessitates a substantial modification in therapy, including dose escalation and multiple daily doses.

From a pharmacological stance, the management of such a change does not pose difficult issues. It can, however, create substantial stress for the patient and clinicians involved in the treatment of the addiction disorder. Because the drug has been classified as addiction therapy, as opposed to pain therapy, some patients express disbelief in the analgesic efficacy of methadone. Others wish to continue the morning dose for addiction even if treatment throughout the remainder of the day uses the same drug at an equivalent or higher dose. Some clinicians who work at methadone clinics are willing to continue to be involved and prescribe opioids outside the program, and others wish to relinquish care.

Selecting Appropriate Drugs and Route of Administration for the Symptom and Setting

The use of long-acting analgesics in sufficient amounts may help to minimize the number of rescue doses needed, lessen cravings, and decrease the risk of abuse of prescribed medications, given the possible difficulty of using short-acting formulations in patients with substance abuse histories. Rather than being overly concerned regarding the choice of drug or route of administration, the prescription of opioids and other potentially abusable drugs should be carried out with limits and guidelines.

Recognizing Specific Drug Abuse Behaviors

In an effort to monitor the development of aberrant drug-taking behaviors, all patients who are prescribed potentially abusable drugs must be evaluated over time. This is particularly true for those patients with a remote or current history of drug abuse, including alcohol abuse. Should a high level of concern exist regarding such behaviors, frequent visits and regular assessments of significant others who can contribute information regarding the patient’s drug use may be required. To promote early recognition of aberrant drug-related behaviors, it may also be necessary to have patients who have been actively abusing drugs in the recent past submit urine specimens for regular screening of illicit or licit but unprescribed drugs. When informing the patient of this approach, explain that it is a method of monitoring that can reassure the clinician and provide a foundation for aggressive symptom-oriented treatment, thus enhancing the therapeutic alliance with the patient.

Using Nondrug Approaches as Appropriate

Many nondrug approaches can be used to assist patients in coping with chronic pain in advanced illness. Such educational interventions may include relaxation techniques, ways
of thinking of and describing the experience of pain, and methods of communicating physical and emotional distress to staff members (see Table 38–2). While nondrug interventions may be helpful adjuvants to management, they should not be perceived as substitutes for drugs targeted at treating pain, or other physical or psychological symptoms.11,25

Inpatient Management Plan

In designing the inpatient management of an actively abusing patient with advanced illness, it is helpful to use structured treatment guidelines. While the applicability of these guidelines may vary from setting to setting, they provide a set of strategies that can ensure the safety of the patient and staff, control the patient’s manipulative behaviors, allow for supervision of illicit drug use, enhance appropriate use of medications for pain and symptom control, and communicate an understanding of pain and substance abuse management.11,25

Under certain circumstances, such as actively abusing patients who are scheduled for surgery, patients should be admitted several days in advance when possible to allow for the stabilization of the drug regimen. This time can also be used to avoid withdrawal and to provide an opportunity to assess whether modifications to the established plan are necessary.11,25

Once established, the structured treatment plan for the management of active abuse must proceed conscientiously. In an effort to assess and manage symptoms, frequent visits are usually necessary. It is also important to avoid drug withdrawal and, to the extent possible, prescribed drugs for symptom control should be administered on a regular scheduled basis (see Table 38–2). This helps to eliminate repetitive encounters with staff that center on the desire to obtain drugs.11,25

Treatment management plans must be designed to represent the clinician’s assessment of the severity of drug abuse. Open and honest communication between clinician and patient to stress that the guidelines were established in the best interest of the patient is often helpful. However, in cases where patients are unable to follow these guidelines, despite repeated interventions from the staff, discharge should be considered. Clinicians should discuss this decision for patient discharge with the staff and administration, while considering the ethical and legal ramifications of this action.11,25

Outpatient Management Plan

Alternative guidelines may be used in the management of the actively abusing patient with advanced illness who is being treated on an outpatient basis. In some instances, the treatment plan can be coordinated with referral to a drug rehabilitation program. However, patients who are facing end-of-life issues may have difficulty participating in such programs. Using the following approaches may be helpful for managing the complex and more difficult-to-control aspects of care.

Using Written Agreements

Using written agreements that clearly state the roles of the team members and the rules and expectations for the patient is helpful when structuring outpatient treatment. Basing the level of restrictions on the patient’s behaviors, graded agreements should be enforced that clearly state the consequences of aberrant drug use.11,25 A sample contract for the initiation of opioid therapy is provided in Figure 38–1. This template can be modified and structured to fit individual practices and clinics, but it is a good general indication of the responsibilities of the patient as well as the provider.

Guidelines for Prescribing

Patients who are actively abusing must be seen weekly to build a good rapport with staff and afford evaluation of symptom control and addiction-related concerns. Frequent visits allow the opportunity to prescribe small quantities of drugs, which may decrease the temptation to divert and provide a motive for not missing appointments11,25 (see Table 38–2).

Procedures for prescription loss or replacement should be explicitly explained to the patient, with the stipulation that no renewals will be given if appointments are missed. The patient should also be informed that any dose changes requires prior communication with the clinician. Additionally, clinicians who are covering for the primary care provider must be advised of the guidelines that have been established for each patient with a substance abuse history to avoid conflict and disruption of the treatment plan.11,25

Using 12-Step Programs

The clinician should consider referring the patient to a 12-step program with the stipulation that attendance be documented for ongoing prescription purposes. The clinician may wish to contact the patient’s sponsor in an effort to disclose the patient’s illness and that medication is required in the treatment of the illness. This contact will also help to decrease the risk of stigmatizing the patient as being noncompliant with the ideals of the 12-step program.11,25

Urine Toxicology Screens

Periodic urine toxicology screens should be performed for most patients to encourage compliance and detect the concurrent use of illicit substances. This practice, as well as how positive screens will be managed, should be clearly explained to the patient at the beginning of outpatient therapy. A response to a positive screen generally involves increasing the guidelines for continued treatment, such as more frequent visits and smaller quantities of prescribed drugs.11,25
Family Sessions and Meetings

The clinician, in an effort to increase support and function, should involve family members and friends in the treatment plan. These meetings will allow the clinician and other team members to become familiar with the family and additionally assist the team to identify family members who are using illicit drugs. Offering referral of these identified family members to drug treatment can be portrayed as a method of gathering support for the patient. The patient should also be prepared to cope with family members or friends who may attempt to buy or sell the patient’s medications. These meetings will also assist the team in identifying dependable individuals who can serve as a source of strength and support for the patient during treatment.\textsuperscript{11,25} A final case study illustrates how a highly complicated patient case, with advanced cancer requiring an unorthodox amount of medication, was managed in cooperation with hospice nurses to treat his pain and control aberrant behavior.

\begin{figure}[h]

\includegraphics[width=0.5\textwidth]{image.png}
\caption{Pain management guidelines: opioid medication consent form.}
\end{figure}

\textbf{CASE STUDY}

\textbf{A 39-Year-Old Man with Pancreatic Cancer}

The patient, a 39-year-old man with pancreatic cancer, was referred to the palliative care program shortly after he had opted to forego chemotherapy and radiation therapy, and it was decided he was not a candidate for surgical resection. The patient had presented with advanced disease and a 40-pound weight loss. He had been suffering with abdominal pain for months but was self-treating with sustained-release oxycodone, which he had been abusing and dealing for the last several years. The patient had a very limited life expectancy when first evaluated, and he was not open to considering other opioids or celiac plexus nerve blocks. He stated that he just wanted to be comfortable enough to play with his 3-year-old daughter until he died. The patient always required high doses of medication for comfort (800-mg sustained-release oxycodone b.i.d.) and did
eventually agree to also take adjuvant analgesics and cortico-
steroids. He had remarkably good pain and symptom
management until his death, and even went deer hunting
2 weeks before he died. The provision of supportive care
would have been impossible without the structure provided
by hospice nurses, who delivered 1 day’s worth of medicine
at a time, turned up randomly for pill counts at the patient’s
home, collected urine for toxicology screens, and otherwise
coordinated tremendous levels of family support from those
family members who had been assessed and deemed not
involved with illicit drug use and sales.

Conclusion

Treating patients who are experiencing chronic pain from
advanced illness and a substance use disorder is both compli-
cated and challenging, since each can significantly complicate
the other. The management of an advanced patient who is
actively abusing drugs and is a member of an ethnic minority is
more perplexing due to cultural differences that may exist.
Using a treatment plan that involves a team approach that rec-
ognizes and responds to these complex needs is the optimum
strategy to facilitate treatment. While pain management may
continue to be challenging even when all treatment plan proce-
dures are implemented, the health care team’s goal should be
providing the highest level of pain management for all patients
with substance use disorders.

Special Patient Populations

Key Points

- Quality palliative care is a result of intelligent systematic efforts to raise standards of care.
- Tools are available to assist in the monitoring and measurement of structure, process, and competency in the delivery of palliative care.
- Outcome measures are needed to evaluate the impact of innovative change on patient and family quality of life, health care systems, and professional practice.

One system for addressing health and end-of-life care is the inclusion of quality methodologies designed to improve education, streamline health care bureaucracies, help measure costs, and even address how people feel about their jobs. Whether or not your organization is accredited by the Joint Commission on Accreditation of Health Care Organizations (JCAHO), mandated to use a quality improvement (QI) methodology, a planned-change approach is needed to achieve positive outcomes and to cultivate an infrastructure that maintains optimal standards of care for those at the end of life.

This chapter provides perspectives on QI-based initiatives in U.S. health care organizations across settings and populations, and discusses their impact on patient, professional, and system outcomes in palliative care. Principles of QI and structural, process, and outcome approaches to conducting QI studies are introduced. A case study is presented of a pathway for the end of life that is now being tested and used to establish the linkages between QI principles and practice to improve end-of-life care. The chapter closes by showcasing nurses within interdisciplinary teams who are providing leadership in the field of palliative care.

The Terminology Turmoil

Quality improvement is increasingly commonplace in the lexicon of industry and government health care systems in the United States. Typically, QI is used to describe a process for improving things. Although the terms vary, distinct vocabulary, tools, and techniques used to conduct QI studies are the same. Other labels include continuous quality improvement (CQI), total quality management (TQM), total quality systems (TQS), quality systems improvement (QSI), total quality (TQ), and performance improvement (PI).¹

Because consensus regarding these terms is unlikely, it is recommended that each organization define a methodology
and terms that apply across the board and be consistent in their use. This will encourage users of QI to read beyond labels and to examine the meaning behind concepts and the value of teamwork in achieving goals. For the purposes of this chapter, QI is defined generically as the label for the philosophy driving a systematic approach to improving clinical practice, systems, issues, education, and research.

Quality Improvement in Health Care

What Is Quality Improvement?

As a philosophy, QI is broadly defined as “a commitment and approach used to continuously improve every process in every part of an organization, with the intent to exceed customer expectations and outcomes.” As a management approach, QI is a way of doing business: a way to stimulate employees to become part of the solution by improving the ways care is delivered, identifying the root causes of problems in systems, designing innovative products and services, and evaluating and continuously improving.

The concepts of QI go back to the 1920s, with pioneers in the field such as Deming, Shewhart, Juran, and Ishikawa. W. Edwards Deming, an American engineer and statistician most widely known for his efforts to assist Japan in its quest for quality after World War II, was all but unknown in his own country until the 1980s. In fact, the Deming prize, Japan’s highest award for industrial productivity and quality, was first awarded to an American company, Florida Electric and Light Company, in 1989. To date, no health care organizations have received the Deming prize. Joseph Juran, also involved in the Japanese quality transition in the 1940s and 1950s, added the concepts of planning and control to the quality process and addressed the “costs” of poor quality, which includes wasted effort, extra expense, and defects. Readers wanting more detail about the rationale and statistical methods behind QI philosophy and methods are referred to the writings of Deming and others.

Although Deming’s quality method has been used extensively in industry with much success, it has only been adapted to education and health care since the early 1990s. The U.S. Health Care Reform Act of 1992 fueled the need for QI methods and better control over inconsistencies in services. Effects of the reform include: (1) increased managed-care contracts in health systems and reductions in reimbursement; (2) reorganization and downsizing of hospitals and staff; (3) cross-training and the development of multipurpose personnel; (4) shorter hospital stays for patients; and (5) a shift in the provision of services from hospital care to ambulatory and home care.

Table 39-1 describes six key principles of QI, based on the doctrines of W. Edwards Deming. These principles are being applied to a QI project to improve end-of-life care at Continuum’s Beth Israel Medical Center (BIMC) in New York City. At BIMC, chart reviews of inpatient deaths and other sources of data provided evidence that end-of-life care could be improved. The purpose of the 1-year pilot study, funded by a New York State Quality Measurement grant, is to create a benchmark for the care of the imminently dying inpatient.

The QI process begins and ends with customers, determining their needs, and creating products that meet or exceed their expectations. To achieve the necessary improvement, multidisciplinary teams are needed to break down barriers between disciplines and departments, promote collaboration and mutual respect among health care workers, and encourage participation from front-line staff. In the BIMC pilot study, to determine the causes of variation in end-of-life (EOL) care, a 28-member team was formed to involve staff integral to the EOL process on five pilot units: oncology, geriatrics, hospice, medical intensive care, and step-down unit. Early in the study, QI techniques of brainstorming and flowcharting were used to identify health system barriers and to identify possible strategies for dealing with them.

QI teams use a systematic, scientific approach and statistical methods to study problems and make decisions. This paradigm encourages an environment of life-long learning and promotes a team approach to identifying and developing the “best practices.” The BIMC project identified a critical need for multidisciplinary education and teambuilding. For example, monthly QI meetings included a segment of the American Medical Association’s (AMA’s) Education for Physicians on End-of-Life Care (EPEC) training program. Discussions, led by Russell K. Portenoy, M.D., a co-investigator for the AMA project and chairperson of the QI team, provided team members fundamental information about the components of good EOL care, as well as opportunities to voice their own ideas and concerns.

The QI team worked in four subcommittees over a 5-month period to reach the implementation schedule of the project. One subcommittee developed the Palliative Care for Advanced Disease pathway (PCAD), which has three parts: a multidisciplinary care path, a flow sheet for daily documentation of care, and a physician’s order sheet, that includes suggested medications for treating 15 of the most prevalent symptoms at EOL. The other three subcommittees addressed (1) education of nurses, physicians, other staff, patients, and families; (2) a timeline and detailed plan for implementation, education, and evaluation of PCAD; and (3) tools and methods for evaluating patient, family, staff, and system outcomes of the project.

Effectiveness of Quality Improvement

While many organizations have embraced the notion of using QI to improve cost and quality outcomes, the experience in the United States is relatively new. In fact, a national survey of U.S. hospitals in 1993 found that 69% had adopted or were beginning to implement some form of QI program. Seventy-five percent of hospitals adopting QI had done so within the previous 2 years, studying administrative issues, such as patient scheduling, record-keeping, and billing, rather than clinical practice.

One study provides evidence that quality and outcomes of care can be improved and certain efficiencies achieved through
Improving the Quality of Care Across All Settings

The application of QI. A review of the literature from 1991 through 1997 revealed 42 single-site and 13 multisite QI studies for examination. Of the 42 single-site studies, nearly 60% focused on two major areas: streamlining surgical or medical procedures and reducing length of stay. Thirteen studies addressed overuse of services (i.e., provision of health services when the risks outweigh the benefits); three looked at underuse (i.e., failure to provide health services when benefits exceed risks); and 23 evaluated misuse (i.e., appropriate health services selected but poorly provided). Only two studies used

<tr>
<th>Principle</th>
<th>Discussion</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Customer-driven</td>
<td>The focus is on customers, both internal and external, and understanding them. Teams strive to achieve products/services to better meet needs and exceed expectations of customers.</td>
<td>Chart reviews of patient deaths reveal areas to improve: Documentation regarding advance directive discussions, symptom management effectiveness, spiritual and psychosocial care, treatment decisions in last 48 h of life. Focus groups with caregivers reveal need for better communication with health professionals about patient’s progress.</td>
</tr>
<tr>
<td>2. System optimization and alignment</td>
<td>Organizations/teams are systems of interdependent parts, with the same mission and goals for customers. Optimizing performance of the entire system means aligning the processes, technology, people, values, and policies to support team efforts to continually improve.</td>
<td>Hospital-wide multidisciplinary CQI team is formed to reduce variation in EOL care with three standardized tools that provide guidelines for care (carepath), documentation, and physician orders. Ongoing resources from Pain and Palliative Care available to pilot unit staff (one advanced practice nurse)</td>
</tr>
<tr>
<td>3. Continual improvement and innovation</td>
<td>Focus shifts to processes of care and using a systematic and scientific approach. Methods seek to reduce and control unnecessary process variation and improve outcomes.</td>
<td>Flowcharting and brainstorming techniques help identify current activities and unit norms for EOL care regarding establishing goals of care, advance directives, respecting patient and family preferences, and barriers to implementing goals of project.</td>
</tr>
<tr>
<td>4. Continual learning</td>
<td>Resources are available to develop a culture in which people seek to learn from each other and access new sources of evidence. Feedback mechanisms support the use of evidence to drive improvements.</td>
<td>Extensive literature searches and team expertise guide development of clinical tools and educational materials. Team members receive education regarding issues in EOL care, viewing of Education in Palliative and End-of-Life Care (EPEC). Adult learning principles guide sequencing and content of educational sessions for unit staff (e.g., physiology of dying).</td>
</tr>
<tr>
<td>5. Management through knowledge</td>
<td>Decision-making is based on knowledge, confirmed with facts about what is “best practice,” and guided by statistical thinking.</td>
<td>Team uses FOCUS-PDSA methodology to structure study processes. Content experts in EOL, measurement, outcomes, and QI guide sampling, selected outcome measures, and graphic display of data.</td>
</tr>
<tr>
<td>6. Collaboration and mutual respect</td>
<td>Organizations/teams engage everyone in the process of improvement and in the discovery of new knowledge and innovations. Mutual respect for the dignity, knowledge, and potential, contributions of others is valued by members.</td>
<td>Team forms subcommittees to develop materials in four areas based on expertise and interest: Carepath development, flow sheet, physicians’ orders implementation (timeline for phases of planning, launching, rollout, evaluation, dissemination, and decisions to adopt practice changes) Education (staff, patient, and family) Outcomes (patient, family, staff knowledge, process audit of new tools)</td>
</tr>
</tbody>
</table>
randomized design, while most used weaker designs, such as pre–post observation.

Of the 13 multisite studies, seven addressed misuse of services (i.e., focusing on improving care without questioning the amount of care provided); four focused on appropriateness of care in terms of underuse (e.g., pediatric immunizations rates, use of guidelines); and two examined overuse of services (e.g., length of stay). Only one multisite study used a randomized design. Although some study outcomes included standards for use of guidelines), and focus on patient and care-giver outcomes.

Given the emphasis in health care on using QI to improve quality and cost in health care, nurses can expect to see increases and use of quality indicators, and focus on patient and care-giver outcomes.

Quality Improvement in Palliative Care

The World Health Organization defines palliative care as the “the active total care of patients whose disease is not responsive to curative treatment . . . when control of pain, of other symptoms and of psychological, social and spiritual problems is paramount.” Palliative care is often referred to as supportive care or comfort care that seeks to prevent, relieve, alleviate, lessen, or soothe the symptoms of disease without effecting a cure.

A valuable resource for those working in end-of-life care is the landmark report published by a committee of the Institute of Medicine (IOM), Approaching Death: Improving Care at End of Life. The committee of 12 experts in medical and nursing care for chronically ill and severely ill patients summarized four areas of improvement: the state-of-the-knowledge in end-of-life care, evaluation methods for measuring outcomes, factors impeding high-quality care, and steps toward agreement on what constitutes “appropriate care” at end of life. The four major findings suggest starting points for QI work:

- Patient care: Too many people suffer endlessly at the end of life, both from errors of omission—when caregivers fail to provide palliative and supportive care known to be effective—and from errors of commission—when caregivers do what is known to be ineffective and even harmful.
- Organizations: Legal, organizational, and economical obstacles conspire to obstruct reliably excellent care at the end of life.
- Education: The education and training of physicians and other health care professionals fail to provide them with knowledge, skills, and attitudes required to care well for the dying patient.
- Research: Current knowledge and understanding are inadequate to guide and support consistent practice of evidence-based medicine at the end of life.

Structures for QI and End-of-Life Care

QI Methodologies Provide Structures

Various methodologies can be used as structural elements in a framework designed to support an EOL care program. Such structures also help to explain the interrelationship of parts. One type of structure, a systematic methodology, organizes and guides the activities of people performing QI; a second type assures the validity and appropriateness of a study to improve end-of-life care.

A systematic methodology is needed to conduct a QI study and various models exist, some of them widely recognized in health care. Others have been designed specifically for particular institutions’ QI departments. Although QI models may vary, all of them support QI as an unceasing, organization-wide effort that focuses on improving processes of work. They are not intended for policing or blaming people for errors after the fact. Systematic methodologies provide the infrastructure needed to carry out a study that may span a period of years to reach targeted goals.

Ruskin writes, “Quality is never an accident. Quality is always the result of intelligent effort, intent, and vigilance to make a superior thing.” One frequently used methodology designed to support “intelligent effort” is the FOCUS-PDSA cycle, which illustrates the BIMC team’s application of each step in the cycle (see Appendix 39–1). The details and application of the FOCUS-PDSA cycle and tools and techniques for conducting QI studies have been described elsewhere. This is also sometimes referred to as the FOCUS-PDCA cycle, but will be called by its more commonly used name, the FOCUS-PDSA cycle in this chapter.

The FOCUS-PDSA methodology is briefly described below using the BIMC example. Its first five steps are aimed at team building, clarifying the nature and scope of the improvement needed, and gathering information about the culture and setting in which the study will be done.

FOCUS

- Find a process to improve. The focus for the BIMC study was care of imminently dying inpatients on the five hospital units known to have the highest volume of patient deaths. Chart reviews of patient deaths identified the need for the study.
- Organize to improve a process. A 28-member QI team spanned departments and disciplines to address end-of-life issues, such as ethics, social work, chaplains, pharmacists, nurses, and physicians.
• Clarify what is known. Flowcharts were used to map the ideal process of care and increase dialogue among the team about “why” the care varies. The team’s four subcommittees on care path development; implementation, education, and evaluation searched internal and external sources for evidence and rationale in end-of-life care.
• Understand variation. Brainstorming techniques helped the team elicit reasons for variations in the care process and identify potential barriers. An Ishikawa diagram (to display cause and effect) was used to show the barriers: materials, methods, people, and equipment categories were used. Subcommittees considered the barriers when planning and developing elements of the program.
• Select a process improvement. Four subcommittees of the QI team developed evidence-based interventions, including the three-part PCAD care path, educational materials, and appropriate tools to measure professional, patient, and family, and system outcomes. This step starts the PDSA cycle.

The PDCA Cycle: Plan/Do/Check/Act (also referred to as the Plan-Do-Study-Act [PDSA]). The Shewhart Cycle\(^3\) constitutes the evaluation aspect of the study, and it is repeated until the team reaches its goals. The implementation of these steps during the BIMC pilot follows:

• Plan. In this step, a timeline of activities for the 1-year pilot prepared administration, team members, and others with direction, goals, and resources. The sample timeline in Appendix 39–1 illustrates the various phases involved in launching a project: the planning phase, roll-out or introduction phase, implementation, evaluation, and dissemination and reporting. The study design is created. This includes determination of sample size and selection, what data will be collected and by whom, what tools will be used and when they will be applied, what training will be conducted and by whom, and who will perform data analysis. Table 39–2 outlines principles for assuring the quality of data.

</table>
• Do. The interventions are implemented and data collection begins. In the BIMC study, several premeasures were obtained, including baseline knowledge, using the Palliative Care Quiz for Nurses,14 chart reviews, and focus groups with staff to obtain baseline data.
• Check. The results of data collection are analyzed by the team and the next steps formulated. The BIMC group used the findings from the knowledge pretest to identify areas for continuing education. Through consensus, members agreed that knowledge items answered incorrectly by 15% of staff would be targeted for continued education.
• Act. Action plans are developed. The BIMC team gave feedback to the QI team, pilot units, and the hospital QI department in a quarterly report. Staff requested education in “the physiology of dying.”

Standards of Care Provide Structure

Quality care begins in clinical settings with well-defined standards of care that are accepted as authoritative by professionals. Such standards represent acknowledged conditions against which comparisons are made and levels of excellence are judged. They serve to establish consistency, expectations, and patterns for practice. They articulate what health care professionals do and whom they serve, and they define what clinical services and resources are needed. Standards also provide a framework against which quality of care can be measured and constantly improved.

In QI, the term benchmark is used to refer to “the search for the best practices that consistently produce best-in-the-world results”—the gold standard. Standards of care,15,16 guidelines,17,18 position papers,19–22 principles of professional practice,23–26 and research models for end-of-life care27,28 are increasingly becoming available to improve appropriateness, effectiveness, and cost-effectiveness of care.

If explicit, guidelines can describe appropriate management of specific symptoms and at the same time provide a basis for assessment, treatment, and possible outcomes. However, if the evidence is weak, as is the case for much of end-of-life care, guidelines or standards need to be supported with recommendations made through consensus.10

Processes for QI and End-of-Life Care

Answering the question “What are the processes for giving care to a dying patient?” can generate many ideas for a QI study. Process refers to the series of activities or functions that bring about a result. Nurses’ contributions are critical in the processes of assessment, diagnosis, treatment, and evaluation of patients. Pain, dyspnea, agitation, nausea, diarrhea, and constipation are some important symptoms leading to nursing interventions that can reduce the suffering of dying patients.

To meet the health care reform challenges of high quality at lower cost, there has been an explosion of tools designed to reduce variability in the processes of care. Critical pathways and algorithms are two types of tools that provide useful strategies for nurses to monitor and manage the processes of patient care. These tools define desired patient outcomes for specific medical conditions and delineate the optimal sequence and timing of interventions to be performed by health care professionals.

Clinical Pathways

In the QI context, the term pathways refers to clinical approaches or critical paths that form a structured, multidisciplinary action plan that defines the key events, activities, and expected outcomes of care for each discipline during each day of care. Pathways delineate the optimal sequence and timing of interventions.29 The goal of using a pathway is to “reduce variation” in services and practices, thus reducing costs.30–33 Table 39–3 shows a six-step process for developing pathways. Table 39–4 lists commonly used elements of care and interventions.29 By acting on these aspects of QI to improve EOL care, the BIMC QI team pilot-tested the pathway in oncology, geriatrics, and the hospice setting.

Pilot-Test of a Pathway to Improve End-of-Life Care. The entire QI team at BIMC designed an evidenced-based PCAD pathway consisting of three parts: (1) a Care Path—the interdisciplinary plan of care; (2) a Daily Patient Care Flow Sheet for documentation of assessments and interventions (include-

*Source: Janken et al. (1999) reference 29.*
imminently dying. As patients were identified by nurses as candidates, barriers to implementing PCAD began to surface: patients and families wanted “everything done” to continue curative treatment; a physician evaluated a patient as “fragile” and unable to hear “bad news”; a patient’s physical status changed dramatically in 24 hours, from dying to “rallying” and preparing for discharge; and a house staff physician felt that he was already prescribing PCAD and could not see the benefit of enrollment.

There were several positive outcomes of the PCAD pilot. Results included: (1) a heightened awareness by staff of the disease trajectory (such as initial diagnosis, curative treatment, life-prolonging treatment, palliative care, symptomatic palliative care, and care of the imminently dying) and patient wishes for this admission; (2) increased discussions about the goals of care and the rationale for treatment orders; and (3) development of a systematic process for recognizing patient’s needing referral to hospice and to pain medicine and palliative care for symptom management and family support following discharge.

Debriefing sessions held with staff after a patient died became an important aspect of the PCAD process. Staff were encouraged to discuss their satisfaction or dissatisfaction with the experience of the PCAD pathway. Such questions as “Were the patient’s wishes honored?” “Were unnecessary tests/procedures performed?” “Did the patient have a peaceful death?” “Were symptoms controlled?” “What is the family’s likelihood for complicated grieving and the need for follow-up?” generated much dialogue and opportunities for teaching and grief resolution. Overall, staff expressed appreciation for the opportunity to talk about experiences of patient care and the personal involvement in caring for a patient and family whom they may have known over several admissions. Another positive outcome for unit nurses was using the PCAD Daily Flow Sheet. Staffs report that it provides them with an easy and comprehensive system for documenting the assessment and intervention of key elements in EOL care: comfort; physical, psychosocial, and spiritual care; and patient and family support.

QI team members identified several areas needing improvement during the pilot period: (1) clearer definition and measure of the concept of “comfort”; (2) identifying the best forum for educating voluntary physician staff, who have less unit/hospital involvement than staff physicians; (3) documentation of spiritual care and issues; (4) systematic identification of families at risk for complicated grieving; and (5) resources about local bereavement services and education for families.

Results of the pilot study suggest that PCAD is a means for: (1) increasing multidisciplinary team discussions of patients’ goals of care during hospitalization; (2) reducing the variation in the documentation of care of imminently dying patients, placing emphasis on comfort, patient and family wishes, and closure for caregivers; (3) increasing staff awareness of patients who are imminently dying or in need of palliative care services, long-term care, and hospice; and (4) identifying areas in EOL care for continual improvement in organizational systems, education, practice, and evaluation.

Table 39–4
Routine Elements of Care Paths

- Physical elements

- Diagnostic tests
- Psychosocial and spiritual needs
- Referrals and consultations
- Patient and family counseling and education

Table 39–5
Goals of the Palliative Care for Advanced Disease (PCAD) Pathway

- Respect patient autonomy, values, and decisions.
- Continually clarify goals of care.
- Minimize symptom distress at end of life.
- Optimize appropriate supportive interventions and consultations.
- Reduce unnecessary interventions.
- Support families by coordinating services.
- Eliminate unnecessary regulations.
- Provide bereavement services for families and staff, or
- Facilitate the transition to alternate care settings, such as hospice, when appropriate.

Improving the Quality of Care Across All Settings

Figure 39–1. (continued)
Algorithms and Standardized Orders

Algorithms have also become popular tools designed to deliver consistent, timely care, especially symptom management at end of life. Figure 39-1 shows one example of an algorithm developed at Dartmouth-Hitchcock Medical Center, Lebanon, New Hampshire,37 to improve the management of dyspnea. The tool offers clinicians a methodology for assessing the symptom and its etiology, directing treatment options, and establishing guidelines for pharmacological and nonpharmacological interventions.

The Providence Hospice in Yakima, Washington, is a model program of QI thinking applied in daily practice and service. A pocket-size handbook of standing orders and algorithms, Symptom Management Algorithms for Palliative Care,37 is available for clinicians. The symptom-management algorithms allow for a team approach involving the referring physician, medical director, nurse, pharmacist, patient, and family caregivers. QI results have been positive thus far. In one study, use of an algorithm reduced the turnaround time of medication delivery to home hospice patients from 24–48 hours to less than 2 hours. Other topics in the handbook include algorithms for pain, and other distressing symptoms, such as mucositis, anxiety, and terminal agitation.

Outcomes for QI and End-of-Life Care

Federal and state governments, private purchasers, physicians, nurses, insurers, labor unions, health plans, hospitals, and accreditation organizations, among others, have begun to address some of the significant quality problems in the U.S. health care systems (http://www.ahrq.gov/qual)38 by improving the ability to measure and report the quality of care being delivered. Such reporting prompts a closer look at provider and health care practices, both as feedback for clinicians, and as publicly available scorecards for consumer evaluation. Two approaches are described for measuring outcomes in palliative care improvement efforts: using a single indicator of a quality of service or using multiple measures.

QI Indicators: Measures of Organizational Performance

A clinical indicator is defined as a quantitative measure that can be used as a guide to monitor and evaluate the quality of important patient care and support-service activities.39 Indicators that directly affect quality services include such factors as timeliness, efficiency, appropriateness, accessibility, continuity, privacy and confidentiality, participation of patients and families, and safety and supportiveness of the care environment. Although they are not direct measures of quality, indicators serve as "screens" or "flags" that direct attention to specific performance issues that should be targets for ongoing investigation within an organization.

For institutions that have had a JCAHO survey within the last decade, it is clear that there has been a shift in focus of performance from competence and skills ("Is the organization able to provide quality services?") to productivity and outcomes ("To what extent does the organization provide quality services?"). For example, rather than focusing on whether the institution has a pain management program, surveyors might evaluate whether pain standards have been implemented and if they have had an effect on patients' satisfaction with pain management or patient understanding of side effects associated with specific analgesics.

Indicators reflect a performance measure composed of competence and productivity. Competence means that individuals or the organization have the ability (e.g., education, behavioral skills) to provide quality services; productivity means those abilities are translated into actions that achieve quality outcomes. Indicators also reveal deviations from the norm and may warn of impending problems. The amount and types of resources and expertise available on QI teams will influence the indicators selected to assess quality care. Indicators of care at the end of life, for example, may require a single-item measure, multiple items with a summary score, or multiple tools. Indicators are expressed as an event or ratio (percentage) and can be categorized into structure, process, or outcome indicators that are clinical, professional, or administrative in scope. Three examples are provided below.

1. Structural indicators are derived from written standards of care and need to be in concert with the mission, philosophy, goals, and policies of a department or unit. Structure standards measure whether the rules are being followed. For example, a policy may read that all patients admitted to the hospital require discussion and documentation about advanced directives within 48 hours of admission. A structural indicator might read:

   Number of records with discussion/Documentation of advanced directives

   Number of patients who were admitted to the oncology unit

A structural indicator used frequently in a rapidly changing health care job market relates to competence. This indicator might require that all staff working on a geriatrics unit pass a written exam and demonstrate behavioral competencies related to end-of-life care, including pain management (see Appendix 39–1 for sample knowledge competencies related to end-of-life care, including pain management). For this indicator, a threshold is determined, such as 90% on the written exam and three return demonstrations in the use of the pathway, for what constitutes successful completion in education in EOL care.

2. Process indicators measure a specific aspect of nursing practice that is critical to patient outcomes. Examples of process indicators might include...
Improving the Quality of Care Across All Settings

735

screening, assessments, and management of complications. These indicators describe “How care is to be delivered and recorded.” Sometimes it may be difficult to separate process indicators from outcome indicators. For example, if an improvement study is directed toward reducing discomfort related to noisy respirations (death rattle) in dying patients, the indicator might involve the process of assessment of respirations, obtaining an order, and giving appropriate medication. The indicator might read that within 2 months’ time:

Time medications given to time of relief from noisy respirations (in min)

The total time patient experienced noisy respirations (in min)

3. Outcome indicators measure what does or does not happen to the patient after something is or is not done. More recently, QI teams have strengthened outcome indicators by using research instruments when available. Tools with validity and reliability, for which benchmarking data exist, have a greater potential to predict outcomes and improve practices. For example, an outcome of implementing a multidisciplinary pathway to improve care of dying patients might be to achieve family satisfaction with care at 90% very satisfied, using a 0-to-5 scale (0 = very dissatisfied to 5 = very satisfied). Using one of the items related to satisfaction with care in a standardized tool, an outcome indicator might read that within 6 months’ time:

Number of families scoring very satisfied with care

Number of families completing satisfaction survey

Rapid Cycle Testing

The PDSA process is used in several national Improvement for Healthcare Initiative (IHI) collaboratives to improve EOL care. In this model, teams are formed including senior leadership, acknowledging buy-in and support for the effort from the start. Members are coached by IHI faculty. During a year’s time, with three 1-day educational sessions, online discussions groups, on-site visits by faculty, and telephone conference calls of frequently discussed topics, such as advance directives, pain and symptom management, and bereavement care. Figure 39–2 shows the general approach to sequential PDSA cycles. Teams are encouraged to take make small changes rapidly, and once met, repeat the PDSA cycle with the next phase of the process or move to another process. This method has helped many achieve positive results within weeks to months. Examples of studies can be found in Improving Care for the End-of-Life: A Sourcebook for Healthcare Managers and Clinicians. Encouraging teams to reach their targeted goals quickly reinforces team building and motivates the teams to examine other processes.

Models and Domains to Assess End-of-Life Care

Organizations have shifted their focus from examining the documentation of processes of care to measuring outcomes of care and learning which treatment works best, under what conditions, by which individuals, and at what cost. Although no tested methods currently exist to adequately measure the quality of care at the end of life, efforts are underway to address this need. Results of a controlled trial, the SUPPORT study, support the deficiencies in care, citing the frequency of aggressive medical treatment at end of life (deaths occurring in the ICU) and the lack of adequate symptom management (conscious patients with moderate to severe pain).

Figure 39–3 presents a model used by the BIMC Department of Pain Medicine and Palliative Care for outcomes...
research in the medically ill. The model illustrates the feedback loop between outcomes and health care. Outcomes research requires ongoing data collection and analysis that feeds into the modification of guidelines for clinical practice, resulting in improved patient, caregiver, professional, and systems outcomes, including costs.27 Appendix 39–1 presents BIMC’s Palliative Care Initial Consultation Tool located at http://www.stoppain.org. The tool is used to screen patients for key components of palliative care and resources needed from an interdisciplinary team. The symptom assessment portion of the form is a validated instrument, the Memorial Symptom Assessment Scale-Condensed. This data can be used to evaluate changes in symptoms within individuals and among groups of patients.

The American Geriatrics Society proposes 10 domains to measure performance and assess quality at end of life (Table 39–6).26 Organizations using the Clinical Value Compass4 approach to achieve quality and evaluate outcomes use four broad domains that can be applied to EOL care: (1) clinical outcomes, such as pain, dyspnea; (2) functional health status, such as communication with family; (3) satisfaction, such as perceived symptom relief; and (4) costs, such as caregiver out-of-pocket expenses, inpatient charges.

**Outcome Measures to Assess the End of Life**

Joan Teno, M.D., of the Center for Gerontology and Health Care Research at Brown University, together with faculty and staff at the Center to Improve Care of the Dying, has assembled a comprehensive annotated bibliography of instruments to measure the quality of care at the end of life. The Toolkit of Instruments to Measure End-of-Life Care (TIME) includes a Patient Evaluation, After-Death Chart Review, and After-Death Caregiver Interview.41 A recent addition to the toolkit is the mortality follow-back survey of family members or other knowledgeable informants representing 1578 decedents’ perceptions of the last place of care.42 Teno’s current research project, Data Analysis and Reports for Toolkit Instruments (DART), refines the toolkit and measures for users. Additional outcome measures suggested for improving EOL care are shown in Table 39–7. A review of the current literature related to each tool in the kit can be found at http://www.channel.brown.edu/Teno.htm. Donabedian43 stated that “achieving and producing health and satisfaction, as defined for its individual members, is the ultimate validator of the quality of care.” There has been limited research to date in examining satisfaction among terminally ill patients and families. Yet, for most dying patients, satisfaction may be the most important outcome variable for themselves and their families.

Professor Irene J. Higginson, Ph.D., a leading researcher for more than 15 years has been using the audit cycle, a feedback process similar to QI methods, to improve outcomes in palliative care. Currently at King’s College School of Medicine and Dentistry and St. Christopher’s Hospice in London, England, she notes the difficulties in obtaining outcome information, such

As quality of life, from the weakest group of patients. She supports the need to test the use of proxies to obtain this important information. One tool currently available for clinicians that is used to measure the quality of life for patients with terminal illness is the Missoula-VITAS quality of life index.

Measures of family satisfaction in palliative care such as the FAMCARE scale are also available. FAMCARE is based on qualitative research that asks family members to list indicators of quality of palliative care from the patient’s perspective and their own. A similar instrument, the National Hospice Organization Family Satisfaction Survey, is an 11-item survey that asks about satisfaction with aspects of hospice care.

Summary

Nurses are poised to have pivotal roles in improving the quality of care of the dying in the decade ahead. As nurses, we need to continue to learn what works and what does not work for patients and families in our practice settings, and to stay active in developing and testing QI models, tools, and interventions toward better EOL care. Nurses are providing leadership in areas of clinical practice, education, and research. Nurses are testing interventions for improved symptom management, developing models for assuring “best practices” using research, and integrating QI methods into palliative care curricula in nurses’ education. Nurses will need to strengthen their involvement in national and international efforts that educate professionals and consumers and influence health care policy in EOL care issues.

To survive, health care systems must be able to change and improve. If the quality of EOL care is to improve, nurses will need to have expert knowledge about making change: how to encourage it, and how to manage and to evaluate it within and across organizations and settings. This knowledge needs to be coupled with the methods and know-how to produce change. QI methods and tools are a powerful means for designing and testing strategies to improve EOL care.

**Find a process to improve.**

Set the boundaries by defining the beginning and end points of the process.

**Opportunity statement**

An opportunity exists to improve FOL care for the imminently dying inpatient.

*(Name the process.)*

beginning with a physician's order for the Palliative Care for Advanced Disease care path ending with death or discharge to homecare, hospice, or residential facility.

*(Set boundaries.)*

This effort should improve patient comfort and family satisfaction with FOL care

*(Name outcome measure)*

for hospitalized oncology, geriatric, hospice, and intensive care unit patients.

*(Name the customers.)*

The process is important to work on now because good FOL care is an institutional priority. No benchmarks are currently available in the US, and no standard approach is used at BIMC* to assess and treat patients who are imminently dying.

*(State significance.)*

**Organize to improve the process.**

Form a multidisciplinary CQI team; establish roles, rules, and meeting times.

**Multidisciplinary Team (22 members)**

Understand the variation

Brainstorm with those at the grass roots level about why the process varies. Categorize sources of variation by people, materials, methods, and equipment. Display data using a cause-and-effect diagram.

Brainstorming Session with CQI Team on End-of-life (EOL) Care Question:
What barriers could be encountered in implementing an EOL Pathway at BIMC?

EOL awareness/readiness:
- What is “end-of-life care?” When is treatment palliative vs. life ending? How do we choose?
- Patient, family, readiness/awareness of dying
- Physician, family, patient willingness to acknowledge that death is imminent
- Issues of truth telling: family may not know status of patient prior to the pathway
- Physician discomfort with stopping treatment
- Medical uncertainty about when to stop treatment

Team communication:
- Physician and nurse discomfort in discussing change in treatment strategy
- Is it the physician’s decision alone? The health care team as a whole needs to be acknowledged in decision.
- Definition of terms. Need to define who the team is. May need a new model.
- Nurses’ comfort—may be put in the middle of team/family attending and decisions.

Unit resistance:
- Resistance of unit teams. May see this project as “another thing to do.”
- Large-scale resistance. Some may not see that there is something to “fix.”
- Organizational pressure to discharge quickly.

Knowledge deficit:
- Assumptions about pastoral care (patient, family, staff) and what the experience will be.
- Knowledge deficit about medical and nursing interventions
- How to implement the care path and encourage people to speak up front rather than later
- Large cultural diversity at BIMC
- Education needed about biomedical analysis and ethical problems
- Physician/patient and physician/family communication skills

Cause and Effect (Ishikawa) Diagram (Barriers to implementing PCAD)—Themes above

### ACTIVITY

1. ACTIVITY DETERMINED BY PATIENT’S PREFERENCES AND ABILITY. Patient determines participation in ADLs, i.e., turning and positioning, bathing, transfers

### CONSULTS

1. INITIATE referrals to institutional specialists to optimize comfort and enhance quality of life (QOL) only.

### PSYCHOSOCIAL NEEDS

1. PSYCHOSOCIAL COMFORT ASSESSMENT of:
   - Patient
   - Primary caregiver
   - Grieving process of patient & family

2. PSYCHOSOCIAL SUPPORT: Referral to Social Work
   - Offer emotional support
   - Support verbalization and anticipatory grieving
   - Encourage family caring activities as appropriate individualized to family situation and culture
   - Facilitate verbal and tactile communication
   - Assist family with nutrition, transportation, child care, financial, funeral issues
   - Assess bereavement needs

### SPIRITUAL NEEDS

1. SPIRITUAL COMFORT ASSESSMENT
   - Spiritual supports
   - Spiritual needs and/or distress

2. SPIRITUAL SUPPORT: Referral to Chaplain
   - Provide opportunity for expression of beliefs, fears, and hopes
   - Provide access to religious resources
   - Facilitate religious practices

### PATIENT/FAMILY EDUCATION

1. ASSESS NEEDS AND PROVIDE EDUCATION REGARDING:
   - Goals of Palliative Care for Advanced Disease
   - Physical and psychosocial needs during the dying process
   - Coping techniques/Relaxation techniques
   - Bereavement process and resources

### DISCHARGE PLANNING

1. FOR DISCHARGE TO COMMUNITY: Referral to Pain Medicine & Palliative Care/Hospice/Home Care/Social Work as needed.

2. AT TIME OF DEATH:
   - Post Mortem care observing cultural and religious practices and preferences
   - Provide for care of patient’s possessions as per family wishes
   - Bereavement support for family and staff

The following are medications for consideration in treating pain and symptoms of patients on PCAD:

**PAIN MANAGEMENT**

**For Opioid-Naive Patient:**
Morphine Sulfate 15 mg po or 5 mg SQ/IV.
Repeat q 1 hr until pain relief is adequate. Begin Morphine Sulfate 30 mg po or 10 mg SQ/IV q 4 hr ATC or begin IV Morphine Sulfate basal infusion at 2 mg per hour and 2 mg SQ/IV q 1 hr pm.

**For Opioid-Treated Patient:**
If pain uncontrolled, increase fixed schedule dose by 50%.

Many non-opioid analgesics are available and should be considered after opioid therapy has been optimized. If pain remains uncontrolled, consider consult to Department of Pain Medicine and Palliative Care (Beeper #6702).

**ANXIETY & INSOMNIA**
Lorazepam 0.5mg po/SQ/IV BID-TID q HS for anxiety.
Temazepam 15 – 30 mg po q HS for anxiety/insomnia.
Clonazepam 0.5 – 2 mg po BID-TID for anxiety/myoclonus.

**CONFUSION/AGITATION**
Haloperidol 0.5 mg po/SQ/IV. Repeat q 30 minutes until symptom intensity declines.
Haloperidol 0.5 – 5 mg po/SQ/IV q 4 hr pm.

**CONSTIPATION**
Lactulose 30 ml po q 2 hr pm until constipation relieved.
When symptom improves, begin Lactulose 30 ml po q 12 hr.
Warm Fleet Enema TlW pm

To prevent constipation:
Senokot 1 – 2 tabs po BID and
Colace 1 – 2 tabs po BID.

**SYMPTOMS OF DEPRESSION**
If anticipated survival is in weeks:
Begin SSRI, e.g., Paroxetine 20 mg po daily, and titrate to effect.

If anticipated survival is in days:
Methylphenidate 2.5 mg q 4 hr morning and at noon and escalate daily to 5 – 10 mg q 4 hr morning and at noon or Pemoline 18.75 mg q 4 hr morning and at noon and escalate daily to 37.5 mg q 4 hr morning and at noon.
Higher doses may be needed.

Consider Liaison Psychiatry consultation

**DIARRHEA**
Loperamide 4 mg po q 4 hr pm

**DYSPNEA**
**For Opioid-Naive Patient:**
Morphine Sulfate 5 – 15 mg po or 2 – 5 mg SQ/IV. Repeat q 1 hr, if needed. When symptom is improved, begin Morphine Sulfate 30 mg po or 10 mg SQ/IV q 4 hr ATC; or begin Morphine Sulfate basal infusion at 2 mg per hour and 2 mg SQ/IV q 1 hr pm.

**For Opioid-Treated Patient:**
If dyspnea uncontrolled, increase fixed schedule dose by 50%.
*If breathlessness continues*, add Lorazepam 0.5mg po or SQ/IV pm. Repeat q 60 minutes if needed until symptom intensity declines, then begin 1 mg po/SQ/IV q 3 hr.

Additional therapies may include:
Dexamethasone 16 mg po, followed by 4 mg po/lV q 6 hr
Albuterol 2.5 mg via nebulization q 4 hr pm if wheezing present

**FEVER**
Acetaminophen 650 mg po/PR q 4 hr pm, and/or
Dexamethasone 1.0 mg po/SQ/IV q 12 hr pm

**HICCUPS**
Chlorpromazine 10 – 25 mg po lM TID pm
Haloperidol 0.5 – 2 mg po/SQ/IV TID – QID

**INTRACTABLE SYMPTOMS, MANAGEMENT OF**
Consider referral to Department of Pain Medicine & Palliative Care (Beeper # 6702).

**IV HYDRATION**
Consider decreasing IV rate to 0.5 – 1 liter/24 hr

**NAUSEA/VOMITING**
Metoclopramide 10 mg po/lV q 4 hr pm, or
Prochlorperazine 10 mg po/lV q 4 hr or 25 mg PR q 8 hr pm
with or without Dexamethasone 4 mg po/lV/PRB q 6 hr

**PRURITIS**
Diphenhydramine 25 – 50 mg po/lV q 12 hr
Hydrocortisone 1 % cream to affected areas q 6 hr
Dexamethasone 1.0 mg po daily alone or in combination with above

**STOMATITIS**
Viscous lidocaine 2 % to painful areas prn
Clotrimazole 10 mg troche 5 times daily
Nystatin S & S q 6 hr pm
Magic Mouthwash prn

**TERMINAL SECRETIONS (NOISY RESPIRATIONS)**
Scopolamine patches 1.5 – 3 mg 72 hr, or
Scopolamine 0.4 mg SQ q 4 – 6 hr

PLAN—DO—CHECK—ACT (the Shewhart cycle)

Plan

Create a timeline of resources, activities, training, and target dates. Develop a data collection plan, the tools for measuring outcomes, and thresholds for determining when targets have been met.

Timeline for One-Year Pilot CQI EOL Project

Phase 0 – Planning

Jan – June  
Formalize CQI Team for the development of a clinical pathway.
Clarify knowledge of processes: review literature and existing data sources, conduct brainstorming, flowcharting with pilot units.
Evaluate and synthesize literature, tools, other data gathered.
Identify content for Care Path.
Develop and pilot audit tool for chart reviews.
Create database, codebook, and scoring guidelines for data entry.
Identify patient outcome assessment tools.
Identify family outcome assessment tools.
Identify staff assessment tools.
Refine study tools/procedures.
Develop staff education.
Develop caregiver educational materials.

June 21  
Medical Records review

Aug 2  
Tools Committee review

July 3  
Committee on Scientific OSA Application and Approval

Phase 1 – Launching the Project

August 2  
Meet with hospital leadership—Introduction to Palliative Care for Advanced Disease Care Path
- PCAD Care Path, MD Orders, and Flow sheet
- Timeline for Education/Evaluation

August 11  
Introduction of PCAD Care Path to medical staff
### Phase II – Unit Implementation and Education of PCAD Care Path

<table>

### Phase III – Evaluation

Chart Reviews using Chart Audit Tool (CAT) (Total = 330)

- 20 retrospective audits for 5 pilot units (Total = 100)
- 20 retrospective audits for 2 control units (Total = 40)
- 10 during implementation audits for 5 pilot units (Total = 50)
- 20 post implementation audits for 5 pilot units (Total = 100)
- 20 post implementation audits for 2 control units (Total = 40)

Each patient on PCAD Care Path as admitted.

- Tool: Teno’s After Death (interview or mailed survey)
- Dates TBD
- Staff survey post-tests (4 mo post-initiation of PCAD)
- Tool: Palliative Care Quiz
- Process Audits (PAT)
  Ongoing throughout time patient on PCAD Care Path
- Brainstorming sessions and focus groups with staff to identify education
  1–2 mo after each unit begins PCAD

### Phase IV – Reporting

- April 15, 2002
  Report to grant agency, hospital, and unit staff
Do

Collect data and monitor the intervention until fully implemented.

Palliative Care Quiz for Nurses (PCQN)

<td><strong>F</strong> = False</td>
<td><strong>DK</strong> = Don't Know</td>
</tr>
</tbody>
</table>

1. Palliative care is appropriate only in situations where there is evidence of a downhill trajectory or deterioration.  
2. Morphine is the standard used to compare the analgesic effect of other opioids.  
4. Adjuvant therapies are important in managing pain.  
5. It is crucial for family members to remain at the bedside until death occurs.  
6. During the last days of life, the drowsiness associated with electrolyte imbalance may decrease the need for sedation.  
7. Drug addiction is a major problem when morphine is used on a long-term basis for the management of pain.  
8. Individuals who are taking opioids should follow a bowel regime.  
9. The provision of palliative care requires emotional detachment.  
10. During the terminal stages of an illness, drugs that can cause respiratory depression are appropriate for the treatment of severe dyspnea.  
11. Men generally reconcile their grief more quickly than women.  
12. The philosophy of palliative care is compatible with that of aggressive treatment.  
13. The use of placebos is appropriate in the treatment of some types of cancer pain.  
14. In high doses, codeine causes more nausea and vomiting than morphine.  
15. Suffering and physical pain are synonymous.  
16. Demerol is not an effective analgesic in the control of chronic pain.  
17. The accumulation of losses renders burnout inevitable for those who seek work in palliative care.  
18. Manifestations of chronic pain are different from those of acute pain.  
19. The loss of a distant or problematic relationship is easier to resolve than the loss of one that is close or intimate.  
20. The pain threshold is lowered by anxiety or fatigue.
Check

Analyze findings, graph results, and evaluate reasons for variations. If targets are reached, set a date to stop or decrease the frequency of monitoring. Summarize what was learned.

Sample: Results of Palliative Care Knowledge Quiz, Preimplementation of PCAD
Act on what is learned and determine the next steps. If successful, act to hold the gain achieved and work at making the intervention a part of standard operating procedure. If not successful, analyze the sources of failure, design new solutions, and repeat the PDCA cycle.

Sample: Quarterly Reporting Form

BETH ISRAEL MEDICAL CENTER
PAIN MEDICINE AND PALLIATIVE CARE
QUALITY IMPROVEMENT STUDY REPORT

Title of Study: Improving End-of-Life Care

Date(s) of study:
1st Quarter ✓ 2nd Quarter__ 3rd Quarter__ 4th Quarter __

Interdisciplinary Team: See listing of CQI Team members.

Sample: The Palliative Care Knowledge Quiz was given to all nursing staff preimplementation of the Palliative Care for Advanced Disease (PCAD) Care Path on three of five planned units thus far.

Findings: In this quarter, we report on the results of knowledge surveys. A total of 90 staff from three units has completed the survey thus far. Analyses have been completed on Unit A described below.

Analysis/interpretation: Unit A, above, is used to describe the process of providing feedback to staff. The threshold for competency was set for 80%. Fourteen of twenty items (70%) are targeted for improvement. No formal education has been given thus far. This data will be used to (a) measure change pre and post an educational series and use of the PCAD in practice, (b) determine levels of competency and targeted areas for continued education, and (c) to stimulate discussion and dialogue with the multidisciplinary team.

Conclusion: Continued education is needed to integrate palliative care principles into the mainstream of daily clinical practice.

Action Plan / Step 1: In-services are scheduled in Quarter 2, 2000. All survey answers will be shared. The Pain Medicine and Palliative Care team will lead a discussion, supported by research results, about the 14 items for which staff answered <80% correctly. Three content areas were identified: end-of-life issues, pain treatment and side effects, and philosophy of palliative care.

Step 2: Based on the dialogue and discussion, subsequent in-services using case-based teaching, will be scheduled. A post-test survey is planned following 6 months of implementation PCAD on each unit.

Follow-up plan: We will report progress at monthly CQI Team meetings. Next report will include chart audit results.
PALLIATIVE CARE CONSULTATION FORM

Patient's Name: ___________________________ Date Completed: ______/_____/______

Admission Date: _____/_____/______ Chart #: ______________ Date of Follow-up: _____/_____/______

Days from Admission: ____________ Insurance: ____________ Completed by: _______________________

I. BACKGROUND

2. Age: __________ Date of Birth: _____/_____/______

   [5] Non-English speaking

8. Primary Medical Diagnosis: [1] ____________________________
   [2] ____________________________
   [3] ____________________________

II. COGNITIVE STATUS

11. COGNITIVE IMPAIRMENT
   [1] Normal
   [2] Mild Impairment; some memory loss or cognitive disability, but does not interfere with functioning; some confusion or
   disorientation, but brief and resolves quickly
   [3] Moderate impairment; memory loss, confusion or disorientation interfering with functioning, but no interference with
   activities with daily living (ADL)
   [4] Severe impairment; confusion, delirium, memory loss interfering with ADL; frank mental retardation
   [5] Comatose; vegetative state; not conscious

12. DECISIONAL CAPACITY
   [1] Normal – Has decisional capacity
   [2] Cognitively impaired, but has decisional capacity

III. PATIENT SELF-DETERMINATION/ADVANCE DIRECTIVES

13. Circle all treatment preferences/advance directives, with supporting documents

A. If no Health Care Proxy; Who would you like to speak for you if you were not able to speak for yourself?
   Name: ___________________________ Phone #: ___________________________
End-of-Life Care Across Settings

Beth Israel Medical Center-Department of Pain Medicine and Palliative Care

IV. COMMUNICATION

14. METHOD OF COMMUNICATION

15. DEGREE OF INDEPENDENCE IN COMMUNICATING
   [1] Functional; independent with all aspects of communication (speaking, hearing, sight), with or without glasses, hearing aids, or communication devices
   [2] Moderate assist; communicates ≥50% of the time
   [3] Dependent; unable to communicate with others

V. PHYSICAL/ACTIVITY STATUS

16. PRESSURE ULCERS
   [1] None
   [2] Mild [Stage I/II]: Injury to skin, Partial loss of skin layers
   [3] Severe [Stage III/IV]: Deep craters in skin that extends down to but not through underlying fascia; breaks in skin exposing muscle or bone; extensive destruction, tissue necrosis, or damage to muscle, bone or supporting structures (e.g., tendons)

17. BOWEL AND BLADDER FUNCTION
   [1] Independent in bowel and bladder function, with full self-care, including ostomy/catheter, if present
   [2] Not incontinent, but some assistance needed in managing bathroom or bedpan or ostomy/catheter, if present
   [3] Rarely incontinent; requiring substantial assistance in managing bathroom or bedpan or ostomy/catheter, if present
   [4] Occasionally incontinent; requires full assistance in managing bathroom or bedpan or ostomy/catheter, if present
   [5] Fully incontinent or unable to assist in management of ostomy/catheter, if present
   [6] Don't know

18. PERFORMANCE STATUS
   [0] Normal activity
   [1] Capable of all self-care, is ambulatory, but restricted in physically less than 50% of waking hours strenuous activity, able to carry out work of a light or sedentary
   [2] Ambulatory, capable of all self-care activities, but unable to carry out any work activities; up and about more than 50% of waking hours
   [3] Capable of only limited self-care; confined to bed greater
   [4] Completely disabled; cannot carry on any self-care; nature (e.g., light housework, office work) totally confined to bed/bed

19. NUTRITIONAL INTAKE
   [1] Normal
   [2] Modified Independent; intake limited, need for modification unknown
   [3] Requires diet modification to swallow solid foods and liquids (puree, thickened fluids)
   [5] Tube feeding only
   [6] No oral intake (NPO) and no tube feeding

20. PRACTICAL SUPPORT WITH ESSENTIAL TASKS (e.g., cooking, cleaning, shopping)
   [1] Needs assistance in essential tasks which is not available
   [2] Needs assistance in essential tasks which is often unreliable or incomplete
   [3] Needs assistance in essential tasks which is sometimes inadequate or available only for less critical tasks such as banking
   [4] Needs assistance in essential tasks is usually available; assistance in less critical tasks is incomplete and unreliable; other responsibilities limit helper availability
   [5] Assistance is available and adequate for any need

VI. SOCIAL SUPPORT

21. The emotional support I have had from my family and friends has been:
Beth Israel Medical Center-Department of Pain Medicine and Palliative Care

**VII. SPIRITUALITY** *(Skip if Patient is Globally Incompetent)*

22. How important is your religion or spiritual beliefs in your everyday life?

23. During your current illness, how much comfort and strength are you finding from your religion or spiritual beliefs?

**NOTES:**

---

**SECTIONS VIII - IX TO BE COMPLETED BY PATIENT/FAMILY MEMBER OR HEALTH PROFESSIONAL**

**VIII SYMPTOMS** *(CMSAS-Condensed Memorial Symptom Assessment Scale)*

If the patient has any of the following symptoms, how severe and distressing are they now?

Quality end-of-life care in nursing homes is becoming more important as the number of older adults increases, and managed care continues to minimize hospital stays. Nursing home residents are sicker today and have different care needs. Although nursing homes were not established as sites for terminal care, they are becoming the place where many people do die. Statistics on the place of death tell us little about the environment where someone lived and died. This chapter addresses nursing homes, the environment of nursing homes, the staff, the care of dying residents, and model programs to support dying residents.

The terms institutional care and long-term care have been used interchangeably in reference to nursing home care, although neither is synonymous with nursing home care. Long-term care refers to a continuum of services addressing the health, personal care, and social service needs for persons who need help with activities of daily living due to some functional impairment. Services may be provided in the home, the community, or a nursing home.

Before the late 1970s, nursing homes were the primary source of care that could not be provided by families for persons needing long-term care. Nursing homes have been described as the offspring of the almshouse and boarding house and the stepchild of the hospital. In the mid-19th century, older people who were poor, sick, or disabled and without family support had few options other than the almshouse. Private homes for the aged emerged as an alternative to public almshouses after the passage of the Social Security Act in the 1930s. Women who were caring for their ill family members at home took in other patients to help pay the bills. From these small homes, proprietary nursing homes evolved. When nurses were added to the staff, the homes were referred to as nursing homes, a term that continues to be used today.

Growth of Nursing Homes

The growth of nursing homes from the 1930s to the 1960s was related to six key factors: (1) Old Age Assistance allowed a portion of the elderly to directly purchase services; (2) payments

Key Points

- The long-term care setting is the home for much of the elderly population and a common setting of end-of-life care.
- Unlicensed personnel provide a substantial proportion of long-term care and should be included in palliative care education efforts.
- Elderly residents in long-term care settings often have multiple chronic illnesses and complex medication regimens.

Sarah A. Wilson

Long-Term Care

You know I’m a fighter, and if I wanted to fight I would . . . but I don’t want to fight any more. I just want them to leave me alone, no more tests. Don’t let them do anything else, please promise me.
—Mother, talking to her daughter
were made directly to facilities for the care of older adults, easing the state’s financial obligations and creating a source of payment for care; (3) construction loans and loan guarantees were available through the federal Hill–Burton Act, the Small Business Administration, and the Federal Housing Authority; (4) the Kerr–Mills Program extended financial participation to medically indigent older adults; (5) the American Association of Nursing Homes became a strong lobby for those with interests in the new industry; and (6) the federal government began in a limited way to develop some standards for nursing homes. The growth of nursing homes occurred largely by chance; however, with the passage of Medicare and Medicaid in 1965, nursing homes became an industry.

Nursing homes continue to be a growing industry because people are living longer, with more complex health problems. The latest data (2004) from the National Center for Health Statistics (NCHS) list 18,000 nursing homes, with 1.9 million beds and 1.6 million residents. The majority of nursing homes (66%) are proprietary or profit making. Nursing homes are licensed or certified to designate the level of care provided and method of reimbursement. Approximately 82% of nursing homes are certified by Medicare and Medicaid. Skilled nursing facilities (SNFs) are those certified for Medicare funding. Medicare provides for up to 100 days of skilled care in a nursing home after a 3-day hospitalization. However, reimbursement for nursing home care by Medicare is restricted by narrowly defining what “skilled” is and by limiting the duration of the “skilled” benefit. The cost of nursing home care, averaging $61,320 year, is beyond the means of most Americans. Rates for Medicaid reimbursement vary considerably from state to state. Most elderly who need nursing home care for more than a few weeks spend or liquidate all their resources to qualify for Medicaid.

**Population Demographics and Nursing Homes**

The population of the United States continues to increase. One of the most significant developments is the growth of the older population. The large number of people who were born between 1946 and 1964, commonly referred to as “baby boomers,” contributes to the “graying of America.” Statistics from the 2000 census reflect the influence of baby boomers. Thirty million people are over 65 years of age and account for 12.4% of the population. Sixteen percent of the people aged 65 and over are members of minority groups. The fastest growing age group in the United States are people aged 85 and over. The number of centenarians increased 35% between 1990 and 2000. It is projected that by the year 2011, the largest increase will be in the group of people aged 65 to 74 years. The increase in the older adult population will have a major impact on health care in terms of services needed, delivery of health care, and education of health care providers. Older persons have more health problems, use more health services, and are hospitalized more often for longer stays than younger persons.

Five percent is most often cited as the proportion of older adults living in nursing homes. However, this is misleading because the use of nursing homes increases with age. For older adults residing in nursing homes, 34.6% are aged 75 to 84, and 33.8% are aged 85 to 94. The characteristics and needs of nursing home residents have changed with the implementation of the prospective payment system for Medicare. Nursing homes are experiencing changes in the reasons for admissions and discharges. For example, the intensity of care has increased as more people enter nursing homes as a result of early hospital discharge. Some people are entering nursing homes for a relatively short stay and rehabilitation, others are being discharged home, and still others are being transferred to hospitals in the final stages of life and ultimately die there.

Persons who live to age 65 have more than a 40% chance of living in a nursing home before they die, and this is likely to increase to 46% by 2020. Death occurs more frequently among older adults in institutions than at home among family and friends. A widespread belief is that the majority of older people die in hospitals. In fact, the older people are, the more likely they are to die in nursing homes. It is estimated that 40% to 50% of all deaths will occur in long-term care settings by the year 2040. Although nursing homes were not established as places for terminal care, they are increasingly becoming such facilities.

**Regulation of Nursing Homes**

Nursing homes are highly regulated. The number of rules and regulations have led some to compare the regulations to those of nuclear power plants. The nursing home population is viewed as a population of vulnerable adults who need protection, which, in combination with the history of patient abuse by some providers, has led to a strong tradition of regulation by federal and state governments. Most of the effort in quality assessment has been directed toward detecting problems; less has been devoted to assessing and acknowledging good care. Almost 2 decades ago, concern with the quality of care in nursing homes led Congress to commission the Institute of Medicine (IOM) to study nursing homes. The recommendations of the IOM Committee on Nursing Home Regulation, as well as many consumer advocacy groups, led Congress to enact major reforms in nursing home regulations as part of the Omnibus Budget Reconciliation Act of 1987 (OBRA 87). The intent of OBRA was to improve the quality of care by establishing a single set of certification conditions for all nursing homes. In addition, these regulations addressed residents’ care, rights, and quality of life. A key aspect of OBRA 87 was that residents have the right to be free of physical and chemical restraints. The emphasis of regulations shifted toward addressing outcomes of care. The Minimum Data Set (MDS), a standardized interdisciplinary assessment tool, was mandated for residents within the first 14 days after admission, and whenever there was a significant change in a resident’s condition.

Some improvements have been noted in nursing homes since OBRA 87 was implemented. The focus on residents’ rights and the empowerment of residents in care decisions have...
be identified as one of the most significant accomplishments of OBRA. Perhaps most significant, there has been an overall reduction in the use of both physical and chemical restraints. It is significant that OBRA included no provisions for improving reimbursement to increase staffing. The emphasis of OBRA was rehabilitation, restoration, and improvement in function, not the provision of quality end-of-life care.

Accreditation

Nursing homes may apply for voluntary accreditation by the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), an organization created for the accreditation of hospitals that has expanded to include home health agencies and nursing homes, among other health care institutions. The facility pays a fee for the inspection to determine if JCAHO standards are being followed. Some nursing homes that seek JCAHO accreditation believe that it adds to a facility's credibility and makes it more marketable to the consumer.

In summary, growth in nursing homes has been proportionate with the increasing elderly population, and the need for long-term care services will continue to increase as the population ages. Palliative care is an important component of nursing home care. Along with understanding the structure of nursing homes, it is important to consider the sociocultural environment of these institutions.

Sociocultural Environment of Nursing Homes

The sociocultural environment of long-term care differs from that of hospitals. Whereas hospitals must always have physicians present, nursing homes are required only to have physician services available as needed. A medical director, full-time or part-time, is responsible for coordinating and directing resident services.

Physician Involvement

Physician visits to residents in nursing homes are often limited to once every 30 days. Federal regulations require physicians to make at least one visit every 60 days to nursing home residents, in contrast to the acute care environment, where physicians usually see patients every day. The nurse in the nursing home is responsible for communicating any changes in a resident's condition to the physician. If the physician does not respond in a timely manner, the medical director intervenes.

Length of Stay

The length of stay is either short term or long term. In most nursing homes, the length of stay varies, although there is greater movement of residents into and out of nursing homes as a result of early hospital discharges. The short-term resident is usually someone under 75 years of age who stays in the nursing home for 4 to 6 weeks for rehabilitation after an acute illness, such as a stroke or hip replacement. The long-term resident is usually older than 75 and has numerous chronic diseases and functional and cognitive impairments. The average length of stay in a skilled nursing facility is 870 days from admission to discharge. Almost half (47.7%) of all nursing home residents have some form of dementia. The 1999 National Nursing Home Study indicated that the typical resident is a female, 85 years old and older, who needs assistance with one or more activities of daily living and instrumental activities of daily living. The long-term resident is much more likely to die in the nursing home or hospital. Older people who die in a nursing home have dying trajectories of fragility, with 60% having a diagnosis of a stroke or a hip fracture. Between 50% and 60% of all deaths in SNFs are residents with a diagnosis of dementia.

Nursing Home Staff

Nursing homes and hospitals differ in the type of staff employed and in staffing patterns. The acute care hospital has a higher ratio of professional staff to patients than the nursing home. Nursing assistants, the primary caregivers in nursing homes, spend the most time with residents and constitute more than 32% of a nursing home's full-time equivalent (FTE) employees. In comparison, registered nurses (RNs) constitute only 7.6% of the FTE employees. Licensed practical nurses (LPNs) constitute 10.6% of the nursing home's FTE employees. Approximately 50% of SNFs do not have an RN on duty 24 hours a day. Proprietary nursing homes have fewer RNs (6.8%) per 100 beds than nonprofit or government nursing homes (9.1%).

The educational level and preparation of staff in the two types of institutions also differ. The LPN program may be completed in 12 to 24 months and has a limited amount of educational content devoted to geriatrics, palliative care, and death and dying. Most nursing assistants have not completed high school, work for low pay, and receive few benefits. The work assigned to nursing assistants is often difficult and stressful, with little recognition of their contribution to resident care. The IOM committee strongly supports the need to increase the number of professional nurses in nursing homes, noting that there is a clear connection between the RN-to-resident ratio and the quality of nursing care provided.

Public Expectations

The public and the family of nursing home residents may have unrealistic expectations of nursing homes. It is a difficult decision for families to decide on nursing placement. Families expect the same type of care to be provided in the nursing home that was provided in the hospital. For example, families may believe a physician will visit every day instead of once a month. The media reinforces negative images of nursing homes. Cases of abuse and poor management receive more attention in the media than positive images of nursing homes.
The sociocultural environment of nursing homes differs from other health care institutions: the average length of stay is longer, physician visits are less frequent, the primary care providers are nursing assistants, and RNs constitute a small portion of the home’s FTE employees.

Studies of Death and Dying in Nursing Homes

Early studies of death and dying focused on hospitals as the place of death. The attitudes of hospital staff toward dying patients, the stresses encountered by nurses in caring for dying patients and families, and communication with dying patients and families were described in these studies. More recent studies of death and dying have focused on other settings, including nursing homes. The setting of care has a direct influence on the older adult’s quality of life at the end of life. Studies of death and dying in nursing homes have examined family perceptions of care, symptom management, educational needs of staff, and barriers to quality end-of-life care.

Family Perceptions of Nursing Home Care

Teno conducted the first large national study to examine family perspectives on the quality of end-of-life care in institutional settings and home. Family members were surveyed to determine if the adequacy or quality of end-of-life care differed in hospitals, nursing homes, and home. A mortality follow-up survey was used, and 1,578 decedents were represented. Nearly one fourth of all respondents reported the patient did not receive adequate treatment for pain and dyspnea. Family members of persons whose last place of care was a nursing home or a home with hospice services had higher rates of reported unmet needs for pain compared with persons who had home hospice services. One quarter of the families reported problems with physician communication. Nursing home residents were less likely to have been treated with respect at the end of life. The family members of decedents who received home hospice care were more likely to report a favorable dying experience.

Wilson and Daley, as a part of larger study of death and dying in nursing homes, interviewed family members whose relatives died in nursing homes. Family members described caring behaviors of staff that were helpful to them. The primary concerns expressed by these family members were lack of spiritual care in some facilities and not being present when their relative died because they were not notified in time by the nursing home staff.

Cartwright reviewed nursing research in nursing homes and assisted-living facilities as places of care for the dying. She noted that a large discrepancy exists between family and staff perceptions of the quality of end-of-life care in nursing homes. Wilson and Daley reported that positive long-term relationships exist between staff, residents, and families in nursing homes. There is clearly a need to examine how these relationships can improve communication and impact the quality of end-of-life care.

Symptom Management

One of the major themes reported in the IOM’s study of care at the end of life was that too many people suffer from pain that could be prevented or relieved with the use of existing knowledge and therapies. Several studies have documented the poor control of pain in nursing home residents. Instruments to assess pain in residents with cognitive impairment are inadequate. Issues related to pain management in nursing homes are reviewed below, and a comprehensive discussion of pain assessment and management are found in Chapters 5 and 6.

Palliative care educational programs have been effective in improving pain management in nursing homes. Foggatt evaluated an educational program for nursing home staff that included RNs and nursing assistants. Pain management improved; however, the program did not appear to have an impact on institutional practices and policies regarding end of life. Weissman and colleagues designed an educational program to enhance institutional commitment to pain management. Multiple facilities participated in the project and sent two or three staff members to full-day education classes on pain management. Participants developed an action plan to change facility practice and policies regarding pain management. Fourteen target indicators, based on standards developed by the American Pain Society and Agency for Health Care Policy and Research, were used to evaluate changes in practice and policy. The indicators included: use of standardized assessment and flow sheets; education of staff, residents, and families; establishment of an interdisciplinary pain team; and institutionalization of pain assessment and management polices and quality-improvement standards and processes. Facilities averaged 8.8 indicators in place at the completion of the project. This was a significant improvement from the baseline score of 3.4 indicators. Weissman acknowledged that some indicators were more difficult to change. For example, only 19 facilities had established a pain-education program for staff at the completion of the program.

Educational Needs of Staff

The educational needs of staff have been identified in several studies. Kayser-Jones and Hanson reported that staff often lack knowledge of how to assess and manage symptoms in nursing homes. Wilson and Daley conducted focus group interviews with 155 participants in 11 nursing homes to identify the learning needs of staff. Staff identified the need for education about pain management and comfort measures, grief management, communication skills, and spiritual care. Ersek, Kraybill, and Hansberry reported findings similar to Daley and Wilson in their preliminary studies of educational needs of staff providing end-of-life care in nursing homes.

Daley and Wilson developed a continuing education program to address the learning needs of nursing home staff. One
of the content areas dealt with how to communicate with physicians. Nurses were provided with a guide for telephoning physicians about pain that covered how to prepare for the telephone call and what assessment data to report. Steps in preparing to make the call included stating the purpose of the call, enumerating goals for the resident, and defining what they would like to have happen. Assessment data included such information as location, intensity, and quality of pain, what made it better or worse, and what medications had been tried. Nurses were encouraged to develop a standard form to record information. Six to 8 weeks after the continuing education program, participants were asked to describe how they used information from the course. Nurses indicated that they were more comfortable talking to physicians on the phone and used a more assertive approach. Nursing assistants increased their knowledge of what information to report to nurses. Since nursing assistants spend the most time in direct care activities, it is important that they are included in efforts to promote comfort.

Barriers to Quality End-of-Life Care

The nursing home environment has some barriers to quality end-of-life care. Pain management is an area of concern. Physicians are dependent on nurses to assess and to report pain and may be unaware of measures that can be used to control pain in nursing homes. For example, some physicians are unaware that morphine can be given intravenously in many nursing homes. In addition, LPNs receive little education in pain management. Nursing homes are extremely concerned about state and federal regulations and have few protocols for pain management. Pain management is further complicated by the large number of cognitively impaired residents who are unable to communicate if they are in pain.

There is a lack of evidence-based research in the delivery of model programs for quality end-of-life care in nursing homes. Weissman and colleagues’ work on building an institutional commitment to pain management in nursing homes is one of the few evidence-based practice studies. Many nursing homes are apprehensive about participating in research studies because of the costs involved, both monetary as well as staff time required. Studies are needed to address issues of protection of study subjects, since many elderly persons in nursing homes are unable to give informed consent. It is important that the researchers clearly explain the purpose(s) of the research and its objectives, the potential benefits to the nursing home, the time and costs involved, and the amount of staff involvement necessary. Researchers should meet with nursing home administration and staff during the course of the study to discuss the study progress and identify any problems. They should also meet with family members to explain the research project. Once the study is completed, the researchers should provide feedback to the nursing home.

In summary, studies of death and dying in nursing homes have described family perceptions of care, the educational needs of staff in providing end-of-life care, and problems with pain management. Further study needs to be done to learn more about the experience of dying in long-term care facilities. Institutional policies and practices need to change to achieve better outcomes in the management of pain.

The next section explores issues related to the care of dying residents in nursing homes, including advance directives, ethical issues, spiritual support, provision of hospice services, support for dying residents and their families, and recognition of the impact of loss on staff.

Caring for Dying Residents

A number of issues relate to providing quality end-of-life care in the nursing home environment. Nursing home staff, especially RNs, can make significant contributions to enhance terminal residents’ quality of life.

Advance Directives: Where Are the Letters of Preference?

Nursing home residents have the right to participate in decisions about their care, including end-of-life care. The passage of the federal Patient Self-Determination Act (PSDA) in 1990 required all health care agencies that receive federal funding to recognize advance directives. The purpose of the PSDA was to encourage greater awareness and use of advance directives. OBRA 87 regulations emphasized that residents have the right to self-determination, including the right to participate in care planning and the right to refuse treatments. Residents are usually informed of their rights, including the right to advance directives at the time of admission to the nursing home, a stressful time for both resident and family members. Families report making these decisions in the context of guilt and overwhelming burden related to nursing home admission. There is a large number of nursing homes residents with dementia who have no advance directive or family member to make decisions on their behalf.

When protocols are used to learn what residents want in terms of end-of-life care, there is a decrease in transfer and hospital death at the end of life. Little has been written about the unique situation of chronically seriously ill older adults and their families.

Ethical Issues

Autonomy is based on the assumption that an individual is the best judge of what is in his or her best interest. Nursing homes have been criticized as dehumanizing and promoting dependence. Autonomy gives meaning to one’s life and, in relation to nursing homes, it means being able to direct and influence others in decisions regarding daily living situations. The routines, regulations, and restricted opportunities in nursing homes have been described as enemies of autonomy, and the regimentation contributes to a “loss of control.” Most nursing
homes were designed based on a hospital or medical model of care, which focuses on routines and tasks. The medical model tends to foster a paternalistic approach of “we know what is best.” The physical environment of the nursing home also limits autonomy. Space is limited, with most residents sharing a room and toilet facilities that restrict privacy and space for personal possessions. Residents may also wander in and out of others’ rooms. The environment could be more individualized by using personal furnishings and creating a homelike common area, such as a dining room.

One of the most difficult and sometimes controversial ethical issues involves decisions regarding food and hydration. Food in all societies is part of the ongoing cycle of daily interaction and activity around which much of family life is organized and which is symbolic of life and caring. Families may continue to try to feed their relatives when they are no longer able to eat. Nursing home staff can assist families by explaining that it is normal to lose appetite at the end of life and that the body only takes in what it needs. Trying to force someone to eat may cause more harm than good. Families should understand that there is a risk of aspiration as a person gets weaker. Nursing staff may encourage families to offer small amounts of liquids, ice chips, or Popsicles.

The following case study illustrates some of the ethical issues at the end of life in nursing homes.

**CASE STUDY**

**Mary’s Decision**

Mary, an 82-year-old woman, was admitted to Evergreen Nursing Home after a hospitalization for pneumonia. Prior to the hospital admission, Mary lived by herself in an apartment. She has two adult children, one daughter who is single and lives close to Mary, and a son who lives 200 miles away. The daughter either visits or calls Mary every day, and the son calls about once a month and visits infrequently. Mary has had multiple hospital admissions this past year for a variety of health problems, including congestive heart failure, urinary tract infections (UTIs), and dehydration. While in the hospital, Mary received IV antibiotics for UTI and pneumonia. She became very confused in the hospital and, although the confusion decreased after a few days, Mary was much more fragile. She was not able to manage at home by herself, so the decision was made to admit her to Evergreen. Mary has adjusted well to the nursing home admission and continues to have frequent contact with her daughter. She has recently developed a respiratory tract infection and the staff is considering hospital admission. Mary does not want to go to the hospital, and she does not want anything else done. Mary informed her daughter of her decision not to be hospitalized and commented, “I don’t want anything done for the sake of prolonging my life. . . . God will call me when it’s time.” The daughter was in agreement with Mary’s decision and called her brother to inform him of the decision. The brother was very upset with this phone call and asked how she could agree to this—“everything should be done for Mother.” The brother called Evergreen and informed the staff that he was not in agreement with this decision and would visit his mother this weekend.

What are the issues in this case? Who should be involved in making decisions? Why might this be difficult for the son? What are Mary’s wishes? What are the the benefits or consequences of this decision? Would the American Nurses Association (ANA) Code of Ethics be useful in making a decision? What are the roles of the nurse and physician in this case? Should anyone else be involved? What needs to be done? What can be learned from this case?

To answer the above questions, consider the following: Is the primary issue whether Mary should go to the hospital for treatment of the respiratory tract infection? What does Mary mean by “I don’t want anything done to prolong my life”? Ask her to explain this. Could Mary remain at the nursing home and be given oral antibiotics to treat the respiratory infection? Can a patient who is alert and oriented decide what treatment he or she wants? Would a family conference be helpful to discuss what it means to prolong life and what advance directives are? Could the son have some guilt feelings because he does not see his mother very often? Perhaps the son thinks that not having anything done means no treatment or care. This needs to be explained to him. It would be helpful to clarify what Mary wants to be done. Consider what the outcomes would be if Mary had treatment or did not have treatment. The ANA code of ethics addresses respect for the dignity and worth of all persons, the person’s right to self-determination, and the primacy of the patient’s interest. How do these principles apply to this case? Consider if Mary wants to discuss this decision with anyone else. Perhaps clergy? Does this case illustrate the importance of advance directives and the need for communication among all involved?

**Providing Support to Dying Residents and Their Families**

Nursing home staff may provide support to dying residents and their families in coping with the eventual loss of the family member. It is important that nurses communicate openly with families, explain changes in the patient’s/resident’s condition, and answer questions honestly. Listening is an important communicative skill. Active listening is usually more helpful than judging or giving advice. Effective active listening skills include being able to convey that you want to listen, that you want to be helpful, and that you accept the other’s feelings. When communication is a concern for staff, it may be helpful to role-play some representative situations. For example, role-playing can teach what to say on the telephone when informing a family member that their relative is dying and how to help families decide about options.

Families have identified a number of caring behaviors of nursing staff that helped them cope with the eventual loss of their relative. It was important to families for staff to take the
time to come to residents’ rooms and ask how they were doing. Families also identified that listening to the family’s concerns and getting answers to their questions were helpful. Staff also demonstrated concern for families in other ways, such as asking if they would like a cup of coffee or getting a comfortable chair for a family member. Families appreciated the fact that the staff respected their privacy and seemed to know when they wanted to be left alone.

It is important for families to understand the dying process. Staff may explain signs and symptoms of approaching death to families and keep them informed of what is changing and why. If the family is not present, they should be kept informed by telephone. Family decisions, such as being present at the time of death or not being present, should be respected. Every effort should be made to notify families early enough that they may be present at the time of death, if that is their wish. Families may be encouraged to reminisce together. They may participate in providing care by holding a hand or giving a back rub. Staff should remind families that even though the family member cannot respond, the sound of familiar voices may be a source of comfort.

There are some barriers to providing support for dying residents and families in the nursing home environment. The lack of privacy in most nursing homes is a problem, and it is often difficult to find a private area to talk to families and residents. One social worker commented that “dying is almost a public spectacle in the nursing home.” Another barrier is the lack of staff time to spend with dying residents and families, as the staffing patterns of most nursing homes do not take into account labor-intensive care at the end of life.

### Providing Spiritual Support

An important component of palliative care is spiritual support. Spirituality is often associated with religion, but the two are not identical. Religion is a means of expressing spirituality and refers to feelings, beliefs, and behaviors associated with a faith community. Spiritual needs include the need to see one’s self as a person of worth and value, to love and be loved, and to have meaning and purpose in life. Spiritual support is an integral part of supportive care. The search for meaning or spiritual comfort at the end of life is often guided by religious or philosophical beliefs. Spiritual well-being in relation to the end of life has been described as “meaningful existence, ability to find meaning in daily experience, ability to transcend physical discomfort, and readiness for death.” Families and residents may fear the future and have questions about life in general. Residents are usually asked about their religious affiliation and the name of their clergy at the time of admission to most nursing homes, but, unfortunately, this may be the only time spirituality is mentioned. Spiritual needs vary and can change at the end of life.

Private, religiously affiliated nursing homes usually have pastoral care available, and most have a room that is designated as a chapel. Many nursing homes have funeral and memorial services for residents. Nonprivate nursing homes usually attempt to make arrangements for pastoral care through volunteer clergy in the community. Some have been successful with these arrangements, but some nursing home staff have stated that it is difficult to find clergy when needed.

Meeting the spiritual needs of dying residents and their families has been identified as an educational need of nursing home staff. Staff often are aware of spiritual needs but are unsure of what to do or say and what would be considered acceptable to their facilities in meeting spiritual needs. Staff may use a number of interventions to provide spiritual care, including praying with the resident and family, reading the Bible or other religious works, singing hymns, and providing therapeutic presence, all of which may help decrease the loneliness and separation persons are experiencing. When a resident is expressing a spiritual need, the following matrix (Table 40–1) may be useful in responding or making suggestions.

<table>
<thead>
<tr>
<th>Need</th>
<th>Danger Sign</th>
<th>Response</th>
<th>Suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>To be person of worth</td>
<td>Person says, “I can’t even get dressed.” “I’ve made a mess of my life.”</td>
<td>“God loves you.” “I like you just the way you are.”</td>
<td>Address residents with their names to confirm their value and worth. Spend time with them. Find tasks the resident can do.</td>
</tr>
<tr>
<td></td>
<td>Person arranges to get ignored, such as someone who avoids interactions with others or withdraws from interactions.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Love and to be loved</td>
<td>People who are lonely</td>
<td>Express your feelings to resident.</td>
<td>Help resident recall memories of being loved.</td>
</tr>
<tr>
<td>Meaning and purpose</td>
<td>Not being able to do what they used to</td>
<td>Convey that resident did and does make a difference. “You have let me journey with you.” “Part of the gift I get is that you let me take care of you and experience you as a person.”</td>
<td>Assist resident with other meaningful activities: journaling, helping other residents, praying for others.</td>
</tr>
</tbody>
</table>
With proper staff education and training, most barriers to providing spiritual support in nursing homes can be eliminated. Continuing education programs need to be developed to address staff needs for education on spirituality. Staff need to know the facility’s policies regarding spiritual care. Many nursing homes do not have a space designated as a meditation room or chapel. It is important for families and residents to have a private, quiet area where they can meditate. If pastoral care is not available in the nursing home, it may be arranged by contacting local clergy or lay leaders in the community.

Providing Support for Staff

Nursing staff form an attachment to residents that may be defined as a strong emotional bond and connectedness that develops between residents and staff over time. Attachment is fostered by staff efforts to treat residents as “family.” The nursing home is “home” for many residents, as some live there for years, so that staff often experience feelings of loss and sadness when a resident dies.

Staff members need to be able to talk about their feelings of loss when a resident dies. It is necessary for nursing homes to develop programs to assist staff in coping with the loss of a resident. Allowing staff time to talk about a resident at staff meetings, sharing memories of a resident, and planning a memorial for residents who have died may be helpful. Other staff members should acknowledge that the loss must be difficult when they know a particular staff member was close to a certain resident.

The loss of a resident may also be stressful for other nursing home residents. Residents develop friendships with other residents over time; they may have shared a room with the resident or sat next to the resident for meals. The death may remind residents of their own mortality. Residents may want to attend the funeral of the deceased resident, or the nursing home may have a memorial service or time of remembrance. Staff should acknowledge the loss and what it means to other residents.

In summary, the nursing home environment influences the care of residents at the end of life. Nursing home staff need to be comfortable talking with residents and families about death and dying. Knowledge of pain management is as important in nursing homes as it is in other settings. Families should be included in the care of dying residents, and their need for privacy should be respected. Several model programs have been developed to address the unique needs of nursing homes, as described in the next section.

Model Programs to Provide Support to Dying Residents

A number of nursing homes throughout the United States have developed model programs to provide support to dying residents and their families. Some of these programs deal with the specific problems of a subset—those nursing home residents who are near death. Exemplar programs are described below.

Kansas City Regional Long-Term Care Ethics Consortium

Ethical issues are encountered by most health care institutions in the delivery of care, and nursing homes are not an exception. When ethical dilemmas do arise, in-house resources may not be available to resolve the issue, and the nursing home may not have an ethics committee. The Kansas City Regional Long-term Care Ethics Consortium, supported by the Midwest Bioethics Center, developed policy guidelines and ethical consultation and education for long-term care facilities. The mission of the Consortium is to provide a supportive network for people who serve long-term care residents either directly or indirectly. The Consortium has monthly meetings, quarterly case reviews, and educational programs. It provides an opportunity for long-term care professionals to come together and discuss problems and learn from each other. They have been active in advancing palliative care in long-term care. Information about the program may be obtained from http://www.midbio.org.

Abides Ministry

Abides Ministry addresses a variety of the needs of dying residents. It is a model program developed by Luther Manor, a long-term care facility in Milwaukee, Wisconsin. The program was initiated when a group of nurses began talking about how important it was to sit with residents who were dying. Members consist of staff who volunteer after-hours, residents at Luther Manor, and others from the community who want to be present for those who would otherwise die alone.

The Abiders try to anticipate the needs and wishes of dying residents. Abiders sit with a resident and read Bible passages, sings hymns, or most often just hold a resident’s hand. Abiders stay with the dying resident 24 hours a day. They also provide relief for family members. Other nursing homes have developed similar programs using volunteers to sit with dying residents.

Palliative Care and Hospice Care in Nursing Homes

Several nursing homes have contracts with hospices for services. Because the nursing home is considered the resident’s home, he or she may be eligible for Medicare hospice benefits under home care. The hospice staff is responsible for the plan of care, and any changes in the treatment plan must be discussed with and approved by the hospice case manager. The hospice nurse visits the nursing home, arranges the assessment of the resident, and schedules nursing assistance to provide personal care. The resident is provided with services that would otherwise not be available.

Coordinating hospice care in a nursing home requires good communication between the nursing home staff and hospice staff. Nursing home staff may view the hospice staff as outsiders.
Nursing home staff frequently believe that they know the resident best because they interact and care for the resident every day, whereas hospice staff members may see the resident only two or three times a week. Although hospice care is a benefit to residents, some question why special services are available to one group of residents and not to all residents. Hospice care in nursing homes results in better symptom management and improved quality of life at the end of life. However, hospice is underutilized in nursing homes. Information on palliative home furniture, and plants. Pictures and biographical sketches isolate residents on a distant unit. The households were made to explain the study and asked for permission for the relative (CPR) be initiated. The researchers met with family members for comfort, physical complications, and behaviors associated with dementia. The project was guided by the following research homes in Milwaukee, Wisconsin for residents with end-stage dementia. The project was guided by the following research goals: comfort, quality of life, dignity, support for family, and support for the staff. The goal for comfort was that staff be able to tell when a resident was experiencing discomfort and when a resident was not. Staff used physical and behavioral assessment skills to recognize discomfort. When a resident displayed a change in behavior, he or she was evaluated for signs of constipation and for signs and symptoms of common infections, such as urinary tract infection using a leukocyte esterase dipstick. Urinary tract infections were common. If the cause for discomfort was not clearly identified, a behavioral intervention, such as distraction, quiet time in the resident's room, or music therapy, was initiated. All residents had orders for Tylenol as needed. If the resident displayed behavior such as agitation or perseverance and behavioral interventions were not effective, nurses were instructed to administer Tylenol rather than a chemical restraint. To promote the goal of quality of life, each resident had a schedule of activities that balanced sensory-calming and sensory-stimulating activities. Staff had identified that residents often received too much stimulation from the environment.

The goal of human dignity was enhanced by treating all residents in a kind and caring manner and respecting resident choices when possible. A written care plan was developed for each resident to aid communication. Interventions were developed to include the goal of the family being an integral part of care planning. Families were surveyed at regular intervals to determine their satisfaction with care. A bulletin board was hung for families to share information, and a periodic family night was held that focused on friendship and support. The final program goal was that staff have an understanding of behaviors associated with dementia and receive support from one another. Staff participated in educational programs, and every effort was made to assure that the project had sufficient staff to achieve its goals.

This project demonstrated that hospice concepts may be incorporated into the care of persons with end-stage dementia with little additional cost to the facility. The facilities that participated in the project did not require any additional staff. A statistically significant difference in levels of discomfort was established between the treatment and control group, and

Hospice Households for Persons with End-Stage Dementia

The Hospice Households Project for persons with end-stage dementia is an example of an innovative approach that applies hospice concepts in nursing homes. Although the diagnosis of cancer is one of the common diagnoses of hospice patients, cancer is a less common diagnosis among elderly hospice patients in long-term care. The care of persons with end-stage cancer differs from the care of persons with end-stage cancer in that the course of cancer is more predictable. Persons with cancer often have problems with pain, nausea, vomiting, and breathing. These problems are less common in persons with end-stage dementia. The person with end-stage dementia is unable to communicate needs and has severe impairments in cognitive and social abilities. Careful assessment is essential to determine possible causes of discomfort in persons with end-stage dementia.

Five hospice households were developed in three nursing homes in Milwaukee, Wisconsin for residents with end-stage dementia. The project was guided by the following research question: What is the effect of hospice-oriented care on comfort, physical complications, and behaviors associated with dementia for nursing home residents with a dementing illness?

Residents were eligible to participate in the study if they had a diagnosis of irreversible dementia, had a score on the Short Portable Mental Status Questionnaire that indicated severe cognitive impairment, were unable to participate in group programming for persons with dementia, had a functional behavior profile score of less than 40, and had advance directives that requested no cardiopulmonary resuscitation (CPR) be initiated. The researchers met with family members to explain the study and asked for permission for the relative to participate. Residents who met the criteria for participating in the study were assigned to a treatment group or control group. The treatment group received the intervention and were part of the hospice households.

The hospice households were clustered on six-to-eight-bed areas on units that had 22 to 44 beds. The intention was not to isolate residents on a distant unit. The households were made as homelike as possible by using colorful afghans, pillows, home furniture, and plants. Pictures and biographical sketches of each resident whose guardian consented were displayed in the room. Each facility provided a lounge for the project. Residents ate their meals in the lounge, which became a center for activities.

Case managers for the project were selected by the director of nursing in each facility. The case manager led the interdisciplinary team at the facility and assisted with developing and implementing individualized care plans. Case managers received formal classes in hospice care, care planning, assessment techniques, and case management from the researchers. In addition, an all-day conference was held for all staff involved in the project. Classes focused on hospice concepts, dementia, treatment of behaviors associated with dementia, and activity programming, as well as family and spiritual care. The conference generated interest and enthusiasm for the project.

Five main programs goals were identified that are consistent with hospice goals: comfort, quality of life, dignity, support for family, and support for the staff. The goal for comfort was that staff be able to tell when a resident was experiencing discomfort and when a resident was not. Staff used physical and behavioral assessment skills to recognize discomfort. When a resident displayed a change in behavior, he or she was evaluated for signs of constipation and for signs and symptoms of common infections, such as urinary tract infection using a leukocyte esterase dipstick. Urinary tract infections were common. If the cause for discomfort was not clearly identified, a behavioral intervention, such as distraction, quiet time in the resident's room, or music therapy, was initiated. All residents had orders for Tylenol as needed. If the resident displayed behavior such as agitation or perseverance and behavioral interventions were not effective, nurses were instructed to administer Tylenol rather than a chemical restraint. To promote the goal of quality of life, each resident had a schedule of activities that balanced sensory-calming and sensory-stimulating activities. Staff had identified that residents often received too much stimulation from the environment.

The goal of human dignity was enhanced by treating all residents in a kind and caring manner and respecting resident choices when possible. A written care plan was developed for each resident to aid communication. Interventions were developed to include the goal of the family being an integral part of care planning. Families were surveyed at regular intervals to determine their satisfaction with care. A bulletin board was hung for families to share information, and a periodic family night was held that focused on friendship and support. The final program goal was that staff have an understanding of behaviors associated with dementia and receive support from one another. Staff participated in educational programs, and every effort was made to assure that the project had sufficient staff to achieve its goals.

This project demonstrated that hospice concepts may be incorporated into the care of persons with end-stage dementia with little additional cost to the facility. The facilities that participated in the project did not require any additional staff. A statistically significant difference in levels of discomfort was established between the treatment and control group, and
behaviors associated with dementia were lessened in the treatment group, although this difference was not large enough to be statistically significant. Staff reported increased job satisfaction as a result of participating in the project.\textsuperscript{35,37}

\section*{Recommendations for Change}

The quality of end-of-life care in nursing homes can be improved. The following are some recommendations for change: (1) Reimbursement for nursing home care needs to be increased; (2) nursing home staff should include more professional staff, and the ratio of staff to residents should be increased; (3) environmental modifications should be made to improve quality of life and human dignity; and (4) hospice and palliative care concepts should be incorporated in nursing homes.

\section*{Reimbursement}

Reimbursement and regulations in nursing homes are often impediments to quality end-of-life care. Policy makers and the public need to be educated about the cost of nursing home care. Reimbursement should change from an emphasis on procedures to a focus on continuing comfort measures and palliation. Nursing homes receive most of their revenue from private-pay residents and Medicaid. Medicaid rates need to be increased to reflect the labor-intensive nature of long-term care. The IOM\textsuperscript{26} recommends that additional research projects on the use of financial and other resources to improve quality of care and outcomes in nursing homes be funded. An issue closely related to reimbursement is the number and type of staff in nursing homes.

\section*{Nursing Home Staff}

The relationship between the ratio of RNs to residents and quality of care has been clearly established in nursing homes.\textsuperscript{17,22,26} Considering the projected growth in the elderly population, the need for RNs in nursing homes is expected to increase. In addition, nursing home residents will be sicker as a result of shorter hospital stays. A major barrier to increased staffing in nursing homes are the fiscal limits of government support. RN salaries are lower in nursing homes than in hospitals, and vacancy rates are higher.\textsuperscript{26} Nursing homes are starting to use advance practice nurses to deal with the complex needs of older adults. Advance practice nurses, geriatric nurse practitioners, and clinical specialists in geriatrics can improve outcomes and contribute to the quality of care.

Nursing assistants provide the most direct care for residents and have the least amount of training. Their work is often difficult, with few rewards—salaries are low and there are few benefits. The care provided by nursing assistants is important to residents’ quality of life, yet they are often paid little more than minimum wage. Interaction with professional staff is limited due to the demands of the nursing assistants’ work. Nursing assistants should be provided with training for their jobs, and salaries should be increased. Efforts need to be made to include nursing assistants as part of the team.

\section*{Environmental Modifications}

The environment of nursing homes needs to be changed to promote resident autonomy and quality of life. Residents should be consulted about the type of living arrangement they prefer. For example, some residents may prefer a single room with space for personal belongings, while others may appreciate sharing the room with someone for companionship. Nursing homes should be designed to accommodate residents’ preferences. Common areas, such as the dining room and lounge, need to be more homelike, with separate conversational areas. Space should be designated for a meditation room to allow residents and families a quiet place. The elderly in nursing homes are often deprived of natural light. Some simple environmental modifications may improve the older adults’ visual abilities—for example, using colors to enhance contrast, using curtains to control glare, and placing chairs in positions to enhance illumination. Biological changes occur within the brain in response to different levels of bright-light exposure, and these biochemical changes may affect hormones and neurotransmitters responsible for regulating mood, energy, sleep, and appetite.\textsuperscript{38} Rosenthal’s\textsuperscript{19} work on seasonal affective disorder describes the effect of seasons and light and dark on a person’s mood and energy level. In the fall and winter months, when it’s dark and cool, people may be more prone to depression and lethargy. Most people feel better on days when the sun is shining. The nursing home environment may be modified to make better use of light by using broad-spectrum fluorescent lights and daylight-simulating lights.

\section*{Incorporation of Hospice and Palliative Care Concepts}

Palliative care concepts should be an integral part of nursing home care. The emphasis of care should be directed toward the quality of life at the end of life. Both the resident and family should participate in care planning. The nursing home environment should be a therapeutic milieu that addresses the physical, psychological, social, and spiritual needs of all residents. Research by nurses is needed to improve end-of-life care in nursing homes. Nurses can make a difference in the quality of end-of-life care in nursing homes. It is hoped that the reader will incorporate some of the suggestions discussed in this chapter to make a difference in the delivery of end-of-life care for nursing home residents.

\section*{References}

Key Points

- Home care for terminal patients can be used to improve their quality of life. Often, home care interventions can be provided on a short-term basis when clients experience a crisis that needs focused interventions.
- Nurses are the leaders and essential members of the home care team. Advanced practice nurses can have an impact on the cost and quality of care provided to terminally ill patients.
- Patients with complex problems need family caregivers who are taught to provide care in the home. Caregiving can be extremely stressful for family members and may adversely affect the health of the caregiver. Home care providers should assist family caregivers to maintain their health.
- Palliative home care should be provided by a team of providers, including physicians, mental health workers, therapists, nurses, and paraprofessionals.

Originally, palliative care in home care nursing was associated with patients who were clearly near the end of life. The contemporary philosophy of palliative care had its beginnings in England in 1967, when Dame Cicely Saunders founded St. Christopher’s Hospice. Home and respite care continue to be a major component of that program. Palliative care, by definition, focuses on the multidimensional aspects of patients and families, including physical, psychological, social, spiritual, and interpersonal components of care. These components of care need to be instituted throughout all phases of the illness trajectory and not only at the point when patients qualify for hospice services. Palliative care also needs to be given across a variety of settings and not be limited to inpatient units.

The primary purpose of palliative care is to enhance the quality and meaning of life and death for both patients and loved ones. To date, health professionals have not used the potential of palliative care to maximize the quality of life of patients in their homes. In this chapter, we discuss home care as an environment that provides unique opportunities to promote palliative care for patients and families throughout their illnesses. The chapter gives background information on what home care is, its historical roots, the types of providers available to give services, the regulatory policies controlling its use, examples of models of palliative home care programs, and recommendations to professionals for facilitating the use of home care in palliative care, concluding with a case study illustrating key elements of palliative care provision in the home.

Historical Perspective on Home Care Nursing

The period spanning the middle of the 20th century, during which patients were routinely cared for in acute care hospitals, may turn out to have been but a brief period in medical history. Before that time, patients were cared for primarily at home by their families. Today social and economic forces are
interacting to avoid hospitalization if possible and to return patients home quickly if hospitalized. Although at face value these changes seem positive, they have highlighted gaps and deficiencies in the current health care delivery system.

Scientific advances have allowed us to keep patients with diseases such as cancer alive increasingly longer despite complex and chronic health problems. The burden of their care usually falls on families, who often are not adequately prepared to handle the physically and emotionally demanding needs for care that are inherent in chronic and progressive illnesses. In addition, family members often become primary care providers within the context of other demands, such as employment outside the home and competing family roles. The necessity among most of the nation’s family members to assume employment outside the home and to alter those arrangements when faced with a sick relative has created an immeasurable strain on physical, emotional, and financial resources. The increasing responsibilities of the family in providing care in the face of limited external support and the consequences of that caregiving for patient and family raise important challenges for clinicians.

The origins of home care are found in the practice of visiting nursing, which had its beginnings in the United States in the late 1800s. The modern concept of providing nursing care in the home was established by William Rathbone of Liverpool, England, in 1859. Rathbone, a wealthy businessman and philanthropist, set up a system of visiting nursing after a personal experience, when nurses cared for his wife at home before her death. In 1859, with the help of Florence Nightingale, he started a school to train visiting nurses at the Liverpool Infirmary, the graduates of which focused on helping the “sick poor” in their homes.

As in England, caring for the ill in their homes in the United States focused, from its inception, on the poor. Compared to the upper and middle class who received frequent visits from the family physician, either in their homes or in the hospital pay wards, treatment of the sick poor seemed careless at best. Visiting nurse associations (VNAs) in the United States were established by groups of people who wanted to assist the poor to improve their health. During 1885 and 1886, visiting nurse services developed in Buffalo, New York, Boston, and Philadelphia that focused on caring for the middle-class sick as well as the sick poor.

During World War II, as physicians made fewer home visits and focused instead on patients who came to their offices and were admitted to hospitals, the home care movement grew, with nurses providing most of the health and illness care in the home. Up until the mid-1960s, not-for-profit VNAs were developed in major cities, small towns, and counties throughout the United States. Under their auspices, nurses focused on providing health services to women and infants and illness care to the poor in their homes, while most acute care was provided to patients in hospitals.

The face of home care in the United States changed dramatically with the passage of an amendment to the Social Security Act that enacted Medicare in 1965. Home care changed from almost exclusively care for well mothers and children and the sick poor to a program that focused on care of the sick elderly in their homes. In 1967, there were 1753 home care agencies, a large percentage of which were not-for-profit VNAs. In 2003, more than 35 years later, there were 7265 home care agencies, with the largest percentage of agencies represented by the proprietary sector. Not only did the types of agencies change, the acuity of patients increased and the development of technology allowed for the delivery of highly complex care in the home setting. The structural changes in the health care delivery system associated with the passage of the Medicare legislation in 1965 provided the foundation for the contemporary practice of home care nursing in the United States.

The 1990s brought a new challenge, managed care, to health care in general and home care specifically in the United States. The most significant impact of managed care on home care was a decline in the number of visits allowed per patient per episode of illness. The result was a decline in the amount of home care patients received, causing a stabilization of the rapid growth in the home care delivery system. The American Balanced Budget Act of 1997 (PL 105–33) mandated the implementation of a prospective payment system for home care for Medicare beneficiaries. In this system, home care agencies receive a designated dollar amount per episode of illness to provide care for a Medicare patient based on the patient’s admitting diagnosis and other factors related to physical and functional status. Just as the Diagnostic Related Group (DRG) system caused a significant decline in the number of hospital beds in the 1980s, the prospective payment system for home care has resulted in significant shrinkage of the home health care industry due to patients receiving fewer visits per episode of illness.

**Definition of Home Care Nursing**

Home care, home health care, and home care nursing can be confusing terms to both providers and consumers, because they are often used interchangeably. Numerous definitions of home care have been provided by the many professional and trade associations that address home care issues (National Association for Home Care, Consumer’s Union, American Hospital Association, American Medical Association, Health Care Financing Administration, etc.). Common to all the definitions is the recognition that home care is care of the sick in the home by professionals and paraprofessionals, with the goal to improve health, enhance comfort, and improve the quality of life of clients. Home care nursing is defined here as:

... the provision of nursing care to acute and chronically ill patients of all ages in their home while integrating community health nursing principles that focus on the environmental, psychosocial, economic, cultural, and personal health factors affecting an individual’s and family’s health status.
Home Care Use in the United States

Home care is a diverse industry that provides a broad scope of care to patients of all ages. In 2000, it was estimated that slightly less than 8 million people received home care services for acute illness, long-term health conditions, permanent disability, and terminal illness. Although home care is provided to a large number of people, it still represents a very small percentage of national health care expenditures. Home care represented only 3% of the total national health expenditure in 2000, while hospital care consumed 40% and physician services 22%, demonstrating the cost-efficient nature of home care practice.

The majority of patients (67.5%) who received home care were discharged primarily to urban home care agencies. As the reimbursement for home care visits decreases and the cost of home visiting in rural areas increases because of increased travel time, many rural home care agencies have been forced to close, limiting access to home care for the population in the region. The federal government has been inconsistent in its payment of the “rural add-on” to home care agencies who provide care in rural settings.

The demographic picture of home health care recipients shows a predominately female (64.8%) and white (75.8%) population. The majority (70.5%) of home care patients are 65 years of age and over, although home care is provided to patients of all ages, from birth to death. The most common primary diagnosis for home care patients is diseases of the circulatory system, most often heart disease. Other common primary diagnoses of patients receiving home care are diseases of the musculoskeletal system and connective tissue, diabetes mellitus, diseases of the respiratory system, injury, and poisoning. A primary diagnosis of malignant neoplasm represents only 5% of home health care patients, while it accounts for 52% of all patients in hospice. Clearly, nonhospice home care has not been used adequately as an integral part of care for cancer patients and families as they endure the physical and emotional demands of complex cancer treatments and move across the acute, chronic, and terminal phases of their disease. This is an ideal context in which the need for palliative care should drive an increased use of home care services.

Types of Home Care Providers

Home care providers are traditionally characterized as either formal or informal caregivers. Informal caregivers are those family members and friends who provide care in the home and are unpaid. It is estimated that almost three-quarters of the elderly with multiple comorbidities and severe disabilities who receive home care rely on family members or other sources of unpaid assistance. More than 75% of those providing informal home care are female, and nearly 33% are more than 65 years of age. Eighty percent of informal caregivers provide assistance 4 hours per day, 7 days per week. The type of care provided by informal caregivers ranges from routine custodial care, such as bathing, to sophisticated skilled care, including tracheostomy care and intravenous medication administration. Informal caregivers assume a considerable physiological, psychological, and economic burden in the care of their significant other in the home. When layered on top of existing responsibilities, caregiver tasks compete for time, energy, and attention. As a result, caregivers frequently describe themselves as emotionally and physically drained. In a qualitative study of 15 family caregivers, Strang and Koop found that several factors facilitated or interfered with caregiver coping. One factor that interfered with caregiver coping is the competence of the formal caregiver. When formal caregivers were less than competent, they added to rather than reduced the caregiving burden. The economic cost of providing informal care in the home also places a significant burden on caregivers. With the shift toward community-based care, a number of costs have shifted to the patient and caregiver. Out-of-pocket financial expenditures include medications, transportation, home medical equipment, supplies, and respite services. These costs are nonreimbursable and often invisible but are very real to families who are trying to provide care on a fixed income.

Formal caregivers are those professionals and paraprofessionals who are compensated for the in-home care they provide. In 1998, an estimated 662,000 persons were employed in home health agencies. In home care, nurses represent 36% of the formal caregivers providing care to patients in Medicare-certified home care agencies. Home health aides also represent a large proportion of the formal caregivers in home care and are expected to increase in number in the upcoming years. The professionals and paraprofessionals who represent the range of home care providers in home health agencies are described in Table 41–1.

Reimbursement Mechanisms

Home health services are reimbursed by both commercial and government third-party payers as well as by private individuals. Government third-party payers include Medicare, Medicaid, CHAMPUS, and the Veterans Administration system. These government programs have specific requirements that must be met for the coverage of services. Commercial third-party payers include insurance companies, health maintenance organizations (HMOs), preferred provider organizations (PPOs), and case management programs. Commercial insurers often allow for more flexibility in their requirements than Medicare. For example, the home care nurse may negotiate with an insurance company to obtain needed services for the patient on the basis of the cost-effectiveness of the home care plan, even though that service may not be routinely covered.
Medicare

Medicare is a federal insurance program for the elderly (65 and over), the permanently disabled, and persons with end-stage renal disease in the United States, and is the single largest payer for home health services. To be eligible for this program, an individual or spouse must have paid into Social Security. Medicare is a federal program and, as such, the benefits are the same from state to state. The Centers of Medicare and Medicaid Services (CMS) (formerly called Health Care Financing Administration [HCFA]), a department in the federal government, regulates payments for services under Medicare. The rules developed by CMS that guide the Medicare program are detailed in the Health Insurance Manual–11 (HIM–11). CMS contracts with insurance companies called fiscal intermediaries (FIs) to process Medicare claims that are submitted from home care agencies.

Since agencies are now reimbursed using a prospective payment methodology, home care has gained increased flexibility for the services provided under Medicare. In the former fee-for-service model, designated and specific home care providers were paid for each visit made. Today, home care agencies are responsible for assuring that the patients achieve their health outcomes in the most efficient manner. If a home care agency believes the most effective plan of care would be to integrate alternative and complementary therapies, or mental health therapy into a patient’s plan of care, it will not reduce or increase the amount of payment received from the government.

There are five criteria, summarized in Table 41–2, that a patient must meet for home care services to be reimbursed by Medicare.

Medicare is the main payer of hospice services in the United States under the Medicare Hospice Benefit, which Congress first enacted as part of Medicare Part A in 1982 under the Tax Equity and Fiscal Responsibility Act (TEFRA; P.L. 97–248). The law was in effect from 1983 to 1986, when Congress made hospice a permanent part of the Medicare program.12 The impetus behind Medicare’s hospice benefit came from the recognition that the regulations and restrictions for traditional Medicare were not well suited to meet the needs of terminally ill patients.

Medicare hospice was designed primarily as a home care benefit that included an array of services to assist care providers in the clinical management of the terminally ill in the home.4 However, the regulations for hospice care also require home care providers to have in-patient hospice beds available for terminally ill patients who are unable to remain in their homes. Recognizing that hospice is a philosophy of care rather than a place for care, it seems appropriate that hospice care is given in a variety of settings.

In order for a patient to elect the Hospice Medicare benefit, the patient must waive the traditional Medicare benefit. By electing the Hospice Medicare benefit, the patient is acknowledging the terminal nature of the illness and opting no longer to have curative treatment.

Medicaid

Medicaid is an assistance program for the poor, some disabled persons, and children. Unlike Medicare, Medicaid is jointly sponsored by the federal government and the individual states. Therefore, Medicaid coverage varies from state to state. These differences can often be dramatic and in some cases dependent on the state’s financial solvency. Eligibility for Medicaid is based on income and assets and is not contingent on any previous payments to the federal or state governments.

Unlike the requirements of the Medicare program, Medicaid covers both skilled and unskilled care in the home and usually does not require that the recipient be homebound. To qualify for the home care benefits under Medicaid, patients must meet income eligibility requirements, have a plan of care signed by a physician, and the plan of care must be reviewed by a physician every 60 days.

Commercial Insurance

Many commercial insurance companies are involved in health insurance for individuals or groups. These local or national

</table>
companies often write policies that include a home care benefit. Commercial insurers often cover the same services covered by Medicare in addition to preventive, private duty, and supportive services, such as a home health aide or homemaker. Commercial insurance companies cover patients of all ages, including Medicare patients with supplemental insurance policies that cover health care expenditures not reimbursed by Medicare.

Supplemental insurance policies are a source of confusion and anxiety among home care patients, often when families are under increased stress due to the complexity of the health situation for one of its members. Nurses should encourage families to carefully review the specifics of the supplemental insurance policy, including copays, annual review of benefits, anticipated out-of-pocket costs, and pharmacy costs. Families should recognize that when changing a supplemental insurance carrier, you may also have to change the home care provider, since some supplemental policies state which home care provider will be reimbursed for services.

Commercial insurance often includes a maximum lifetime benefit as part of the policy. The high cost of high-technology care forces a growing number of patients to reach this maximum rather quickly and face the loss of coverage. This has resulted in the development of case-management programs administered by insurance companies. The case manager projects the long-term needs and costs of care for the patient and develops a plan with the patient to meet those needs in a cost-efficient manner. Consideration is given to the life expectancy of the patient in relationship to the maximum lifetime benefit.

Unlike the Medicare program, in which negotiation for services is not an option, it may be important for home care nurses to identify the needed services for a patient with a commercial insurance plan and intervene to obtain funding for those services. When working with an insurance case manager, the home care nurse must be specific about the services the patient will need, the overall cost of those services, and the expected outcome related to the services requested. The more precisely the home care nurse can portray the impact of the care plan on the patient outcomes with objective data, the more inclined the case manager will be to authorize services. Insurance companies are very concerned with the satisfaction of their enrollees. Patients and families should be empowered to make their voices heard about the services they need to remain safe in the home. If out-of-network services or special pricing is negotiated with the insurance case manager, written documentation of the agreement should be included in the patient’s record. Ideally, the patient should be given a copy of this agreement in the event that any disputes over payment occur.

The Home Health–Hospice Connection

In order for a patient to receive the full array of hospice services under Medicare, the care must be provided by a certified hospice provider. To be reimbursed, home care agencies that are not certified hospice providers must refer their terminally ill patients to an agency that carries the certification. This regulation affects clinical care in several ways. Home care nurses have a long history of developing strong and intimate bonds with patients and families. As patients progress toward the terminal phase of their illnesses, it is emotionally difficult for home care nurses to refer their patients to hospice providers. At times, it is equally as difficult for a family to accept the referral, knowing that they will have to give up “their nurse.” The home care nurse and the family may believe that the relationship that has developed among the patient, the family, and the home care nurse is more important than any additional benefits the hospice might bring.

The greater flexibility in traditional Medicare regulations that came with the resolution of the Duggan vs. Bohan case in 1988 has allowed nonhospice home care agencies to provide extended nursing and home health aide services for patients in the terminal phase of illness. In this legal case, a group of home care agencies challenged the HCFA (now CMS) regarding their strict interpretation of the Medicare regulation on patient qualifications for part-time intermittent care. The suit was won by the home care agencies, requiring HCFA to be more generous in interpreting Medicare regulations. Although families may feel that they are getting sufficient home care, they are not able to take advantage of the prescription drug components of the hospice benefit, which may result in significant financial burden. They also usually do not receive the supportive services, such as pastoral care and bereavement follow-up, that are integral to the hospice program. Because the emotional impact of the patient’s death is unknown at the time the patient makes the decision to forego a hospice referral, it is impossible to predict the significance of a service such as bereavement follow-up. Because both the nonhospice home health agency and the hospice provider offer important services, especially nursing care to patients at the end of life, strengthening mechanisms that facilitate transitions between these two types of services is essential. See Chapter 2 for a comprehensive discussion of the hospice admission criteria, including the certification by the physician of a terminal diagnosis and the 6th-month rule.

Cancer as a Prototype for Home Care Use in Palliative Care

Over the years, cancer has shifted from a terminal illness to a chronic disease. Even patients with advanced disease and guarded prognoses initially may be treated as if their disease is curable rather than progressive and terminal. Because the philosophical underpinnings and goals of curative and palliative treatments are quite different, approaching an individual who has advanced disease with a curative stance may have long-term negative effects on physical, social, and emotional functions that ultimately affect the patient’s quality of life. Characteristics of advanced cancer that require coordinated palliative care include multiple physical needs, intense emotional distress manifested by anxiety and depression, and complex patient and caregiver needs. The goals of palliative care
are best achieved if care is initiated early on, and one of the most efficient ways of monitoring patients’ needs is to coordinate the overall plan of management with home care nursing to decrease fragmentation and promote continuity.

Needs of Cancer Patients

Because of the growing trend to discharge hospitalized patients early, the increasing use of ambulatory care services, and the increasing use of complex therapies, the need for ongoing monitoring and instruction of patients and families has never been greater. Family members, often without the assistance of any formal home care services, are assuming primary responsibility for the care of patients at home.14–17 This demand on families is not new, although the caregiver role has changed dramatically from promoting convalescence to providing high-technology care and psychological support in the home. Members of a patient’s family are of vital importance in meeting the patient’s physical and psychosocial needs and accomplishing treatment goals.18,19 The burden of caring for patients with a diagnosis of cancer, however, may adversely affect families who lack adequate resources or who are insufficiently prepared for this new, complex role. There is mounting evidence that changes in family roles and the burden placed on family caregivers may have negative effects on the quality of life of both cancer patients and their families, particularly during advanced stages of cancer.

Research to identify patient-defined home care needs began in the 1980s and has increased steadily since the 1990s. Evidence suggests that both patients and their families benefit from home care services directed at physical and psychological concerns. An early study20 identified pain, sleep, and elimination management as major patient needs. Wellisch and his colleagues21 investigated the types and frequency of problems experienced by two separate groups of seriously ill cancer patients and their families in their homes in the Los Angeles area and explored the types of interventions that helped to reduce the problems. The five most frequent problem categories identified included somatic side effects, including pain; patient mood disturbance; equipment/technology problems; family relationship impairment; and patient cognitive impairment. Interventions reported to be effective included reinforcement to the patient and family, no intervention, and counseling and emotional support. They noted that patients with cognitive deficits had special needs, and their family members were at high risk for ongoing problems.

In Pennsylvania, Houts and colleagues22 found that the unmet needs of patients with cancer included assistance with emotional problems, transportation, finances, and interactions with medical staff. Wingate and Lackey23 identified the needs of patients and primary caregivers in the home and compared the priorities between the two. Both identified their psychological distress as their highest priority. For patients, physical and informational needs were next. For caregivers, household management needs, which included direct patient care, were second, followed by informational needs. McCorkle and colleagues24 followed 233 cancer patients for 6 months after they were hospitalized. Half of the patients were newly diagnosed (n = 115); the other half had had their cancers for more than a year. Patients were discharged with a range of complex problems, including unrelieved symptoms (pain, fatigue, dyspnea, poor appetite), wound care, feeding devices, elimination devices, intravenous medication administration, and other highly technical procedures, such as tracheostomies. The majority of these patients were followed as out-patients and not referred to formal home care services for monitoring, despite their ongoing needs, primarily because they were under 65 years of age. Evers and colleagues25 assessed whether the needs of younger patients differed from the palliative care needs and experiences of older adults. They found significant differences across age groups on clinical characteristics, advance care planning, and service use. Patients over age 80 had a reduced prevalence of cancer, a higher prevalence of dementia and incapacity, more frequent decisions to withhold life-sustaining treatments, and fewer interventions for symptom management.

Needs of Caregivers

A number of studies have identified the needs of patients and family members who provide care to patients with cancer. A study by Grobe and colleagues26 described what information was provided to 87 patients in the advanced stages of cancer and their caregivers. This study revealed that families perceived that little, if any, education was provided to them. Hinds27 conducted a study examining the perceived needs of 83 family caregivers who reported they felt inadequately prepared to provide care for their sick relatives in the home and identified numerous information and skill deficits. Morris and Thomas28 identified that caregivers are often “tacked on” to patients and seen as co-clients, but unfortunately are not fully recognized and, consequently, do not receive appropriate information or are not taught the skills to provide care to loved ones. Siegel and colleagues29,30 divided caregiving tasks into categories of personal care, instrumental tasks, and transportation. Each of these areas was associated with greater caregiver demands as patients’ physiological factors worsened or if their caregivers associated their care with a high level of burden.

Oberst and colleagues31 assessed the demands on cancer caregivers, including their perceptions of providing care in the home environment. Caregivers reported that the majority of their time was spent providing transportation, giving emotional support, and maintaining the household. More than one third of the caregivers reported a lack of assistance from health professionals in providing care. In addition, demands on the caregivers escalated as the treatment regimen progressed. Another study lends support to the sense of isolation and the stressful nature of caregiving in that 83% of a sample of cancer caregivers failed to use available resources to assist them in caregiving activities. In addition, 77% of the caregivers reported increased stress, and 28% required medication to help them cope with the burden associated with caregiving.32
These accounts present persuasive documentation that caring for a person with cancer is a stressful experience and can have major emotional and physical consequences for caregivers.

In their review of caregiver research, Sales and colleagues concluded that a significant number of cancer caregivers exhibit psychological distress and physical symptoms. Predictors of caregiver distress included a number of patient-related variables, including more advanced stages of cancer, disability, and complex care needs. Given and colleagues reported that patients’ distress associated with their symptoms, poor mobility, and increased dependency with instrumental activities were linked to significant burdens for family caregivers. They designed a study to test the impact of a 16-week nursing intervention on depressive symptoms of caregivers of patients newly diagnosed with cancer. One hundred twenty-five patient caregiver dyads were recruited and 89 completed the study. The nursing intervention delivered to the experimental group consisted of symptom management and monitoring, education, emotional support, coordination of services, and caregiver preparation to care. Nurses made five home visits and four telephone calls over time. The intervention was effective in slowing the rate of depressive symptoms rather than decreasing the levels of depression in these caregivers. They concluded that the caregivers with higher levels of depression were the ones who withdrew from the study, limiting their effects of the intervention.

Similarly, Carter described sleep and depressive symptoms in 47 caregivers of patients with advanced cancer and found severe fluctuations in sleep patterns. Caregivers reported they suffered progressive sleep deprivation that affected their emotions and ability to continue as caregivers. In another study, caregivers reported that they perceived discomfort in their loved ones who withdrew from the study, limiting their effects of the intervention.

In general, the literature on the needs of cancer patients and caregivers of cancer patients highlights: (1) that patients are increasingly being treated in ambulatory clinics and have ongoing, unmet complex care needs with little or no use of home or palliative care referrals; (2) that caregivers are assuming more and more responsibility for monitoring patients’ status and providing direct care in the home with no opportunities for respite; (3) that caregivers have a high proportion of unmet needs themselves; (4) that the caregiving experience encompasses both positive and negative elements; and, (5) that the conceptualization of caregiver burden is linked to negative reactions to caregiving.

**Models of Palliative Home Care Programs**

A number of studies have tested interventions to develop models for palliative home care. Both patients and their caregivers have served as subjects of these studies. Some examples are highlighted.

**Patient Programs**

Hinton questioned whether home care can maintain an acceptable quality of life for patients with terminal cancer and their relatives. He defined quality-of-life outcomes to include mood, attitude to condition, perceived help, and preferred place of care. The study included 77 randomly selected patients followed by the hospice palliative home care service at St. Christopher’s Hospice in England. Overall, the results were extremely positive. Patients’ physical symptoms were tolerable, caregivers’ depression and anxiety were limited, and the majority of care provided in the home (90%) was complemented by hospitalizations for 1 to 3 days (30%) or longer (41%). Treatment was usually praised by relatives, and at follow-up, relatives approved where patients had received care and had died. In countries other than the United States, home care is an integral part of well-planned palliative care, and a number of palliative home care programs have demonstrated positive patient and caregiver outcomes.

The most recognized model of palliative home care was developed at St. Christopher’s Hospice, yet programs in other countries have been equally committed, including programs in the United Kingdom, Canada, Sweden, and Italy. These programs included hospice-like services, but, more importantly, they were targeted at symptom management and not limited to imminent dying and death. They also encompassed the care of the patient and the family and facilitated transitions from hospitals to homes. In the authors’ opinion, the main reasons these programs have been successful have been not only the commitment and passion of nurses, but also the involvement of physicians who recognize their interdisciplinary role in the palliative care component of patients’ diseases, and the government reimbursement systems.

In the United States, some attempts have been made by other than traditional home health agencies to integrate palliative care into home nursing care. Martinson’s seminal study of facilitating the management and death of children in rural Minnesota after discharge from an urban medical center demonstrated that families wanted and assumed the responsibility to provide necessary care with supervision of the specialty nurses from the medical center. Much of the teaching and instruction was provided to families over the telephone.

Yates and his colleagues designed a study to compare two groups of patients with advanced cancer who were treated in rural Vermont. The patients were paired based on population density, distance from the medical center, socioeconomic status, local medical facilities, referral patterns, and local social service resources. The groups were divided into intensive and nonintensive groups. The intensive group received regular home visits by nurse practitioners, and the nonintensive group was not visited by nurses. Both groups received the same multidisciplinary care from the Vermont Regional Cancer Center and monitoring of cancer status through the ambulatory cancer clinic. A total of 199 patients (98 in the intensive group and 101 in the nonintensive group) were followed, and at the end of the 4-year study 139 patients had died. The results were very
positive in demonstrating that patients in the intensive group fared better overall than those in the nonintensive group. They demonstrated less need for medical care at the cancer center and greater independence over the course of the study than those in the nonintensive group. Most striking, the home nursing interventions improved individual patient pain management. The authors found that physicians often prescribed pain medications without follow-up monitoring of patient status, whereas the home nurses were vigilant in monitoring patients’ comfort. The nurses also improved patient and family negotiations for available community resources. Although the study failed to show a survival difference between the two groups, the researchers did demonstrate cost-effective outcomes. The study demonstrated a decrease in the overall cost of care by facilitating a greater number of home deaths in the intensive group. They concluded that cost savings occurred without sacrifice of patient well-being and with concomitant advantages in patient pain management.

In a statewide study of home care use patterns among cancer patients in Illinois, physicians were found, in general, to be the primary source of patient referral to home health services. More than two thirds of the sample were referred to home services for the purpose of monitoring health status, more often for postsurgical than postmedical treatment effects. Oncology clinical nurse specialists served as consultants to staff nurses in home health agencies in rural Illinois. Both staff and patients reported satisfaction with this model of care delivery. The clinical specialists spent a majority of their time teaching the nurses specific skills and were readily available by telephone to both staff and patients.

McCorkle and her colleagues have completed several studies to test the role of the advanced practice nurse (APN) on patient outcomes in home nursing care. The first randomized controlled trial was completed in 1986 to assess the effects of home nursing care on either an oncology home care group (OHC) that received care from oncology home care nurses, a standard home care group (SHC) that received care from home care nurses without oncology training, or an office care group (OC) that received whatever care they needed except home care. One hundred sixty-six patients with lung cancer were entered into the study 2 months after diagnosis and followed for an additional 6 months. Participants experienced significant differences in symptom distress and functional abilities. The two home nursing care groups remained less distressed and more independent 6 weeks longer than the office care group. The home nursing care assisted patients in minimizing distress from symptoms and maintaining their independence longer, in comparison to patients who received no home nursing care. As part of the study, the effects of the three groups (OHC, SHC, and OC) were tested on the spouses’ psychological distress during the bereavement period. Of the 100 spouses who participated in the study, 46 patients died. Spouses of the deceased patients were followed for 25 months after the death. Spouses of patients in the OHC group were taught to provide direct care to their loved ones and to sit to be present through the living–dying transition. The OHC nurses served as central coordinators for home nursing care and were available 24 hours a day to answer questions, problem solve, and respond to crisis. Spouses’ psychological distress was significantly lower 6 months after the patients’ deaths and sustained over time in the group cared for by the oncology home care nurses. Findings suggested that the bereaved’s psychological distress was positively influenced and their recovery was hastened by the nursing interventions provided during the terminal phase of illness.

In a second study, McCorkle and her colleagues followed 233 patients who were discharged from seven hospitals with complex care problems requiring home care services. The patients were diagnosed with eight different solid tumors and followed for 6 months. Although all these patients could have benefited from home care, only about half were referred to home care. Patients receiving home care demonstrated improvement in their symptoms, function, and mental health status compared with patients who did not receive home care. Results aided in identifying interventions to help with specific problems related to cancer and treatment effects and were standardized to be tested in a third study.

In the third study, McCorkle and colleagues tested the effect of a standardized nursing intervention protocol (SNIP) on postsurgical cancer patients’ outcomes. This study compared the length of survival of postsurgical cancer patients who received specialized home care intervention by APNs after their surgery to the length of survival of those who received the usual follow-up care in ambulatory settings. One hundred ninety patients (50.7%) were in the intervention group and 185 (49.3%) in the usual care group. Patients in the control group received standard postoperative care in the hospital and routine follow-up in outpatient surgical clinics upon discharge. The home care intervention was designed to enhance recovery from surgery and to improve quality-of-life outcomes. The intervention was developed as a protocol that consisted of standard assessment and management guidelines, doses of content, and schedules of contacts. APNs followed specific guidelines to assess and monitor the physical, emotional, and functional status of patients; provided direct care when needed; assisted in obtaining services or other resources from the community; and provided teaching, counseling, and support during the recovery period. Nurses also functioned as liaisons to health care settings and providers, as well as to patients and families in the provision of technical and psychological support.

At the completion of the study, 93 (44.8%) patients had died. Of these, 41 (44%) were from the intervention group and 52 (56%) from the usual care group. For all patients who died, causes of death were documented. Cancer was listed either as the primary or secondary cause on all death certificates. Other causes listed were pulmonary embolus, heart failure, sepsis, and cardiac arrest. Patients receiving the home care intervention had a longer length of survival than the control group. During the first 3 months after discharge, a total of eight patients in the control group died, and one patient from the intervention group died. The intervention, occurring over a period of 4 weeks immediately after surgery and hospitalization, corresponded to a period when the difference in mortality rate...
between the intervention and control groups was the largest. The combination of physical care and psychosocial support during the acute postoperative period addressed two critical issues. The first was to assist patients and families during the period of transition from hospital to home and to offer education, guidance, and reassurance during high psychological distress and uncertainty. The second was to monitor patients’ physical status and offset potential lethal complications that were most prevalent in the acute postoperative period. This study supports the importance of such nursing interventions during the critical diagnostic and surgical treatment phases and is clearly defined within the realm of palliative care, since many of these patients were diagnosed as late-stage.56

As part of the third study, Jepson and colleagues57 examined changes in the psychosocial status of caregivers of postsurgical cancer patients after the patients’ discharge. Within a week after being discharged from the hospital, patients were randomly assigned to either the treatment or control condition. Patients in the treatment group received a standardized home care intervention over 4 weeks. The intervention was provided by APNs and consisted of three home visits and six telephone calls. The nursing interventions included problem assessment; monitoring of the patient’s condition; symptom management; and teaching caregivers how to problem solve, administer medications, and provide self-care behaviors. Psychosocial status was measured using the Caregiver Reaction Assessment.58 Overall, caregivers’ psychosocial status improved from discharge to 3 months and stabilized thereafter; however, among caregivers with physical problems, the psychosocial status of both patients and caregivers in the treatment group declined over time compared to those in the control group. The researchers concluded that caregivers of cancer patients who have their own physical problems are at risk for psychological morbidity as they assume the caregiving role. They recommended that the health of the caregiver be considered as an essential criteria for the caregiver to assume primary responsibility for the patient’s care at home. In the event the caregiver has a compromised health status, then formal home care services are needed.59 Bradley60 also recommended that assessments must include caregiver health needs and that for home health care to be effective, nurses must conduct caregiver assessments to identify needs that could impair their caregiving abilities.

Naylor and colleagues61 studied the effects of comprehensive discharge planning and home visitation by APNs with a population of elderly patients hospitalized for specific medical and surgical problems, including heart disease, orthopedic procedures, and bowel surgery. Some of these patients had cancer diagnoses. The intervention group received standardized comprehensive discharge planning specific for elderly persons at high risk of poor postdischarge outcomes, APN home visits, and telephone calls. The intervention benefited from the clinical experience of APNs and their abilities in communicating, coordinating, and collaborating with physicians. Outcomes included hospitalization rates, days in the hospital, time to first readmission, functional status, level of depression, patient satisfaction with care, and overall cost of postindex hospitalization health services. Patients in the intervention group were less likely to be readmitted to the hospital, experienced fewer days in the hospital, and had a longer time to the first hospital readmission for any reason. Patients in both groups had improved functional status and depression scores and were satisfied with their care. Overall costs for postindex hospitalization health services for the intervention group were half that of the control group. The results of this study indicated that a comprehensive intervention including home care by an APN has a significant positive effect on patient outcomes and the cost of care for high-risk elderly patients.

Caregiver Programs

There have been a number of programs developed to teach caregivers direct care responsibilities for patients in the home that have had positive outcomes on patients and caregivers. Ferrell and colleagues62 examined the impact of cancer pain education on family caregivers of elderly cancer patients. Fifty family caregivers of elderly patients who were at home and experiencing cancer-related pain were recruited for participation in this quasi-experimental study. Outcomes included quality of life, knowledge about pain, and caregiver burden. Caregivers reported significant burden associated with pain management, particularly psychological distress. The pain education program proved efficacious in improving caregiver knowledge and quality of life. Interventions that teach caregivers to become proficient in the physical aspects of patient care indirectly improve the caregiver’s well-being.

A second study that included testing a psychoeducational curriculum intervention was developed by Barg and colleagues.63 The structured education intervention consisted of 6 to 8 hours of intense educational, skills training, and communication-enhancing strategies, to assist caregivers in being more prepared to care for patients at home. Caregivers reported they were more informed about cancer, its treatment, and symptom control. Part of the content, which focused on expected psychological reactions to cancer and to caregiving, helped normalize distressing emotions that were being experienced by patients and caregivers. These experiences provided a great source of relief for the caregivers. Despite a clear program description and the delineation of measurable outcomes, the researchers reported that a lack of willingness by many cancer caregivers to attend group meetings posed a major obstacle to obtaining a large number of participants. Group-style interventions clearly lend themselves to the study of a self-selected sample. The researchers concluded that caregivers who attended groups most likely were those least in need of intervention, since they demonstrated an ability to use social support and had respite care available, making group attendance possible. Alternatively, individualized strategies are needed to assist caregivers who are unable to participate in groups and feel they cannot leave their loved ones.

In another study, Schumacher and colleagues64 described the difficulties that patients and family caregivers encountered...
while participating in a randomized clinical trial related to a nursing pain-control intervention. The intervention group reported they had difficulties in obtaining the prescribed medications, accessing information, tailoring prescribed regimens to meet individual needs, managing side effects, cognitively processing information, managing new or unusual pain, and managing multiple symptoms simultaneously. The researchers concluded that the provision of information about pain management is not adequate to improve pain control in the home, but requires ongoing assistance with problems as they are encountered.

Koop and Strang explored the experience of bereavement following home-based family caregiving of persons with advanced cancer. The caregivers reported both positive and negative outcomes that they attributed to having provided care to their loved one. The positive feelings included feelings of accomplishment and improved family relationships, while the negative feelings included feelings of failure and haunting images of the deceased. Overall positive outcomes outweighed the negative ones and the bereaved family members reported satisfaction with providing care for their loved ones.

Recommendations for Facilitating the Use of Home Care Nursing in Palliative Care

Home care nursing is a logical component of effective palliative care but, for a number of reasons, it has been underused. Patients who need palliative care have complex and often challenging physical and psychological problems. Palliative care for specific types of diseases requires knowledgeable and competent clinicians. It is common for many of the professional staff nurses in home care agencies to lack the knowledge and expertise to manage patients’ symptoms and to teach caregivers the skills they need to manage the day-to-day problems they encounter in caregiving. Yet, because of the barriers described to receiving hospice care, home care nurses have to provide much of the palliative care in the community. In addition, for palliative care to be successful in the home, physicians must work collaboratively with nurses and be available to solve problems as they arise. It is often easier for physicians to admit patients to the hospital than to work with home care nurses to keep patients at home.

The state of the science in home care was reviewed for this chapter. Results from these studies have not been systematically incorporated into clinical practice where services are reimbursed. However, we identified critical factors in these studies that, if adopted, could become the basis of successful home care palliative nursing. These include the following:

1. **Staff nurses who are responsible for direct patient care in the home must have contact and access to APNs with specialized knowledge and skills related to the disease-specific needs of patients.** The term “advanced practice nurse” is defined as a professional nurse who has graduated from a master’s program in a specialty field such as an oncology advanced practice program, including clinical nurse specialists and nurse practitioners. To assist the staff nurse in dealing with the complexity of palliative care, either a palliative care physician or an APN should serve as a supervisor/consultant to the team and be directly involved in clinical decisions. There may be fewer opportunities for APNs than needed working directly in home care agencies because of the perception that they are too costly to employ. As agencies move to prospective payment and greater efficiency, the role of the APN will factor more prominently in home care agencies. APNs may also work independently and provide care to a group of patients, such as case managers from an ambulatory clinic. As a result of the Balanced Budget Act of 1997 (PL 105–55), APNs, specifically clinical nurse specialists and nurse practitioners, practicing in any setting can be directly reimbursed at 85% of the physician fee schedule for services provided to Medicare beneficiaries. In home care, this change has the potential to facilitate access to care for patients who do not have access to a home care agency or other primary care provider, specifically those in rural and underserved areas.

2. **Because of the barriers to entering hospice care, home care nurses should become knowledgeable and highly skilled in providing palliative care to patients.** This will require not only the development of skills in a new area of clinical expertise but also a paradigm shift in the way home care nurses view the episode of care for home care patients. Home care has traditionally been viewed as a component of the long-term care delivery system. Although the number of home visits per episode of illness has decreased significantly, home visits tend to be spread out over a greater period of time, usually a 60-day certification period. For patients requiring palliation, home care may need to be very intensive over a relatively short period of time (2 to 4 weeks). In this model, the home care nurse can assist the patient and family in methods of managing symptoms and coping with the caregiving role. In the long term, as the patient’s disease progresses, the patient and caregivers will need “booster” visits, but the majority of visits and care may be given in short periods of time, when the patient and caregivers are most in need. Telephone visits to provide care have been shown to be an effective strategy for chronic illnesses in which the needs are for support and education. Home care can also be used for short durations in crisis situations. By providing intensive home care for short durations, patients can be helped to address current issues in the most effective way. These short but intensive interventions can improve quality of life.
and may also impact survival outcomes for some patients.
3. Patients are usually hospitalized when symptoms get out of control. When patients are hospitalized, comprehensive discharge planning and follow-up by skilled palliative care nurses is needed to ensure that the plan is implemented, evaluated, and modified as needed. These nurses may be based in a variety of settings, such as home care agencies, clinics, and private offices. The complexity of symptom management following hospitalization may require the advanced skills of an APN to provide consultation to the palliative care team or to implement a plan of care with a patient and family.
4. Patients who have complex problems and receive home care nursing need family caregivers who have been taught skills to provide care. In the event these caregivers are ill themselves, additional or complementary services need to be provided to help with the patients’ care. Nurses providing home care for ill patients should conduct ongoing assessments of family caregivers, including their health and demands made upon them. Standardized educational programs to teach family caregivers skills to provide care are needed and should be a part of routine home nursing care.
5. The use of innovative models must be considered as a strategy for providing care to patients and families. Telephone visits have been shown to be an effective strategy to help families cope with the caregiver role. Under prospective payment for home care, home care providers are no longer constrained by the per-visit method of reimbursement, and telephone visits can be integrated into the plan of care. The use of alternative and complementary therapy, nutritional counseling or mental health therapies has been made financially reasonable due to the move to prospective payment. Telehealth programs have also been used effectively with patient populations at home. Other technology interventions could include the use of the Internet or E-mail. As the technology becomes less expensive, increased opportunity to implement these strategies will occur.
6. While nurses are the hub of the palliative care team, professionals from multiple disciplines should provide palliative home care, and physicians must be an integral part of program management. The multidisciplinary care provided by therapists, nurses, para-professionals, and physicians is essential to the development of positive outcomes. Physicians, as members of the multidisciplinary team, must work in collaboration with other professionals to provide comprehensive care to patients and families. Collaboratively, the team determines the amount of care needed, the most appropriate setting for care, and the type of interventions required to improve the quality of life.

A growing number of cancer patients are being discharged from the hospital following surgery or other cancer treatments to be cared for at home by spouses who have chronic illnesses themselves, as described by the following case study.

Case Study
Mr. And Mrs. Rizzi, Patients with Chronic Illnesses

Mr. Rizzi, a 68-year-old Italian retiree, and his wife, Mrs. Rizzi, aged 64, each have a chronic illness. Mr. Rizzi was diagnosed with Stage IIIA non–small-cell lung cancer following 5 months of chest and shoulder pain, fatigue, dyspnea, weight loss, and persistent cough. Despite his medical history, he was physically active until these symptoms, along with his cancer treatment, constrained him. For 50 years before diagnosis, Mr. Rizzi smoked two packs of cigarettes a day. He also had a history of hypertension, osteoarthritis, and a healing duodenal ulcer.

Mrs. Rizzi was a part-time beautician who identified herself as her husband’s primary caregiver despite her own comorbidities of hypertension, osteoarthritis, and diabetes. These conditions required regular medical management and caused some physical discomfort and loss of mobility. Mr. Rizzi’s treatment included a right upper lobectomy that required chest drainage tubes and subsequent radiation therapy and chemotherapy. He was discharged from the hospital 10 days after surgery. As with many postsurgical patients, Mr. Rizzi went home to be cared for by his wife.

At discharge, Mr. Rizzi’s medical care included wound care at the drain site for postsurgical chest tubes and management of symptoms from the disease and from treatment. He was concerned about his ability to recover and anticipated postoperative pain and loss of his independent, active lifestyle. Despite her own chronic illnesses, Mrs. Rizzi reported her overall health as good and considered herself fit to provide home care. She was determined to help her husband with the physical and emotional needs associated with cancer and its treatment. Mrs. Rizzi was unsure of her ability to manage her husband’s physical care and doubted her ability to distinguish normal postoperative recovery from more serious complications. She was apprehensive about her new role as manager of the family finances and worried about their ability to pay their bills now that physical limitations prevented part-time employment.

Mr. Rizzi was referred for home care at discharge to the local VNA. This VNA was unique in having an oncology APN on staff to consult with the staff nurses on their cases. Mr. Rizzi’s initial assessment visit was conducted within 24 hours following discharge from the hospital. The staff
nurse learned that Mr. Rizzi needed wound care and symptom management related to pain control and bowel regimen. She also conducted a family assessment and learned that Mrs. Rizzi had concerns about her role as caregiver. Recognizing the acuity of the problems identified, and after consultation with an APN, the home care nurse scheduled the Rizzis for daily home visits for a week to address the clinical problems of Mr. Rizzi and provide education to Mrs. Rizzi in the caregiver role. Because maintaining the comfort of her husband was Mrs. Rizzi’s primary concern, the home care nurse taught her about pain management with medications and alternative comfort measures, such as massage, heat and cold applications, and guided imagery. In addition, the nurse referred the Rizzis to the VNA social worker to assist in dealing with the financial issues associated with Mr. Rizzi’s illness. Following the week of intensive home care visits by the nurse, she instituted telephone visits every other day for 2 weeks, followed by weekly telephone calls. Mrs. Rizzi used the telephone calls to discuss changes in her husband’s clinical situation and receive advice on how to manage minor clinical problems. They were also a welcome source of support for Mrs. Rizzi as the complexity of the caregiving role increased. As the care of Mr. Rizzi became more complex, the home care nurse spent a great deal of time reassuring Mrs. Rizzi that she was doing a good job.

One of the critical factors in Mrs. Rizzi’s ability to perform the role of caregiver was the stability of her own health. Given her comorbidities, Mrs. Rizzi might have fallen ill herself under the additional burden of the caregiver role. Instead, the home care nurse coached Mrs. Rizzi to pay special attention to her own health during these stressful times. On each visit and telephone call, the home care nurse inquired about Mrs. Rizzi’s health, making sure she kept her primary care provider appointments and adhered to her medical regimen. Opportunities for respite were arranged so that Mrs. Rizzi could go to get her hair fixed and retain some normalcy in her activities.

As Mr. Rizzi became more ill, Mrs. Rizzi consulted the home care nurse about a hospice referral. The home care nurse consulted with the physician, who agreed that Mr. Rizzi had a prognosis of less than 6 months and was a good candidate for hospice care. Because the VNA did not have a certified hospice program, the home care nurse referred the Rizzis to the local hospice provider in their community. Although it was difficult to discharge the Rizzis from the home care agency, at the hospice, Mr. and Mrs. Rizzi took advantage of the pastoral care services, art therapy program, and the additional resources available under Medicare, such as prescription drug coverage for medications related to the terminal illness. The hospice nurse provided the majority of direct care, with consultation with their APN on the team when Mr. Rizzi’s pain increased. Mr. Rizzi died at home following a 2-month service from hospice. The nurse was present with Mr. Rizzi’s family at his bedside when he died. The hospice nurse also visited Mrs. Rizzi twice after Mr. Rizzi’s death, facilitating Mrs. Rizzi’s grief by providing opportunities to review the care her husband received and her responses to his loss.

Conclusion

For palliative care to be a viable component of the service provided by home care agencies, changes are needed in both the structure of home care and the mechanisms for reimbursement. The regulations for the provision of home care under Medicare must be substantively modified to allow increased access to palliative care. Under the current regulations, the physician is the only provider who has the ability to order and to supervise a home plan of care through home care agencies. The literature is consistent in its description of the positive role APNs play in supporting both the patient and family caregivers in the home, yet APNs are not given the authority to direct patient care through home care agencies for patients needing palliation. Exceptions do exist through hospital-based programs. For example, Memorial Sloan Kettering Cancer Center (New York) has a successful hospital-based supportive care program that provides palliative care in the home for patients. This program is directed by an APN, and services are billed through the outpatient service. Regulations that support the critical role APNs play in the clinical management of patients at home who require palliative care and that legitimize the APN’s ability to order and to supervise the plan of care are essential. The few successful models in hospital-based and ambulatory clinics should be implemented in home care agencies.

Additionally, the historical structure of Medicare reimbursement was a disincentive for the use of APNs in home care agencies. Because of the regulatory changes in reimbursement to prospective payment, APNs will play an increasingly important role in the delivery of effective home care. As the demographics of the home care population change and the complexity of clinical problems increase, agencies can ill afford to be without expert clinical providers.

The earlier case study had a successful outcome even though the current home care delivery system is fragmented. The need for palliative care to be integrated into both home care as well as hospice care is essential for the provision of a continuum of care to patients at the end of life. For these changes to be integrated into the care delivery system, regulations need to be changed to allow home care nurses to provide end-of-life care in situations in which hospice care is unavailable, or at the request of the patient or family.

In summary, home care is an important component of palliative care. Clinical and regulatory barriers have forced palliative care in the home to be provided by certified hospices at the end of life. Structural changes in home care are needed to fully integrate palliative care into the home care delivery system. Additionally, the role of APNs must be fully
developed and reimbursement mechanisms established to integrate palliative care into home care for both patients and home caregivers.

REFERENCES

Hospital-Based Palliative Care

We were so grateful that we could bring our dad into the hospital for his last days. We had cared for him at home with the help of hospice for several months. He survived much longer than the doctors and nurses predicted and we just got so tired. At the very end, the Palliative Care team and Hospice helped us get him admitted to our nearby hospital where they cared for him just like we did at home. He was very comfortable for his last two days of life and they let us stay around the clock. It was a gift to be with him those last days without having to worry about whether we could manage his symptoms and doing all of the physical care.—Family member of man dying of pancreatic cancer

- **Key Points**
  - The hospital is the appropriate site of care for some dying patients. It is important for all hospitals to develop a minimum standard of palliative care services that are consistent with the agency’s care delivery model (e.g., primary, secondary, tertiary care).
  - Established internal (e.g., Quality Improvement Committee, Ethics Committee) and external (e.g., Joint Commission on Accreditation of Healthcare Organizations, Center to Advance Palliative Care) hospital-based quality improvement resources and committees can assist with the development or improvement of a hospital’s palliative care program.
  - Early introduction of palliative care principles in the disease trajectory and early identification of appropriate palliative care patients allows for planning to meet patient preference for end-of-life care.
  - It is important to develop infrastructures of care outside the hospital so that alternatives exist to hospital admission at end of life.

One hundred years ago, the cause, age, and place of death were very different from what they are now, at the turn of the new millennium. Table 42–1 compares some characteristics of dying in 1900 and in 2000. Chronic illness and longer life are the legacy of this century. The hospital is a common location for a good portion of end-of-life (EOL) care in contemporary times, despite Americans’ stated preference for death at home.1,2 An analysis of the experience of dying among Medicare recipients (based on claims data for 1995–1996) demonstrated that the incidence of dying in hospitals varies, but in some regions of the United States it approaches 50% (Figure 42–1).3 An additional 25% to 35% of the nation’s elderly die in nursing homes.2,4 Although a percentage of patients experience their final admission in the critical care unit, by and large hospital deaths occur in non–critical care units3 and are likely to be anticipated for hours or days before death actually occurs.5

Several investigators have described the quality of dying in the acute care hospital.6–8 These studies have found that patients experience pain, dyspnea, anxiety, and other distressing symptoms up until the time of death. Table 42–2 summarizes

Map 6.1 Percent of Medicare Deaths Occurring in Hospitals (1995–96)

Medicare enrollees who lived in the Eastern and Southern United States were more likely to die as hospital inpatients than residents of the Western and Northwestern parts of the country. Rates were particularly high in the New York–New Jersey metropolitan area and in Mississippi, and much lower than average in Tucson, Arizona, Ogden, Utah, Bend, Oregon, and Mason City, Iowa.

selected findings of the well-known Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatments (SUPPORT). This multi-hospital, two-phase investigation attempted to alter the quality of the hospitalized adult EOL experience by “reducing the frequency of a mechanically supported, painful, and prolonged process of dying” by increasing communication and improving the provision of information necessary for decision-making among patient, family, and their health care providers.\(^5\)

The discouraging outcomes from SUPPORT and other studies cannot be explained by providers’ lack of awareness or inability to relieve symptoms. Many studies in the area of pain management demonstrate that effective methods exist to relieve cancer pain in 90% of patients.\(^2\) It is also not the case that acute care hospitals employ unskilled, insensitive personnel who allow suffering to occur. Rather, the issue appears largely one of system design. Inpatients are cared for in a system that is designed to provide acute, episodic interventions for patients with reversible disorders. This philosophy is exemplified by hospital policies that require all persons having patient contact to be certified in the provision of cardiopulmonary resuscitation (CPR), so as to be able to rescue any patient who experiences cessation of respiration or heartbeat. The application of this death-reversing intervention is applied to all hospitalized inpatients unless specifically ordered to the contrary. Clearly, in such institutions, patients who are dying are viewed as exceptions that require special additional thought, paperwork, and attention to receive a different sort of care.

Implementation of other tenets of palliative and hospice-type care may not be consistent with standard hospital policy. For instance, having family, friends, pets, and familiar items in the immediate patient environment often requires special exceptions or violations of standard hospital protocols. In many institutions, beloved pets, home audio equipment used for listening to special music, or multiple significant others sitting around-the-clock vigils are considered contrary to standard hospital infection control, electrical use rules, and security policies. As stated by Berwick on the nature of system improvement: “Every system is perfectly designed to get the results it gets.”\(^9\)

In the case of EOL care, it is hard to imagine how hospital-based EOL care could occur any differently than it does. A change in the quantity and quality of deaths in hospital will come about only as a result of fundamental system reform and redesign.\(^10,11\)

This situation ought not to be viewed as discouraging, but rather as a call to action, particularly for nurses. Because people are admitted to hospitals primarily to receive nursing care, much of the care and the system that patients experience can be influenced by nurses at all organizational levels. (Most other types of care, such as physician consultation, diagnostic tests, and pharmaceutical treatments, are available in outpatient or home settings). The information contained in this chapter is usable by all hospital-based nurses, including senior nursing leaders, clinical nurse specialists, nurse practitioners, nurse managers, educators, quality improvement nurses, and especially nurses on the front line at the bedside. Nurses can define, direct, and lead multidisciplinary and interdisciplinary teams and modify efforts at multiple levels of the hospital care system to improve this complex care process.\(^12,13\)

This chapter outlines how nurses and others can take a leadership role in improving the quality of EOL care in acute care hospitals. Some improvements may result from the use of specific “quality improvement” methods, whereas other improvements may not employ this specific process. Although a step-by-step primer on the process of “quality improvement” is beyond the scope of this chapter, a detailed discussion is found in Chapter 39; other excellent sources are also available.\(^14\) In addition, this chapter focuses on methods to reduce hospital admissions at the EOL. Individual and multihospital innovations to improve hospital-based EOL care are described, including examples from hospitals that have used the approach of developing critical pathways and protocols and new services to improve care, such as palliative care consulting teams and

| Main results | There were no differences between the control group and the intervention group on the measures of the study, which included:

- Communication between physician and patients (discussions of CPR preferences)
- Number of days spent in an ICU receiving mechanical ventilation and in coma
- Level of pain reported by patient
- Use of hospital resources

Further, based on interviews with 3357 survivors:

- 40% of patients died in severe pain
- 55% were conscious
- 63% had difficulty tolerating symptoms |

inpatient palliative care units (PCUs). In closing, economic issues that influence the quality and quantity of hospital-based palliative care and future directions complete the discussion.

**Hospital-Based Palliative Care as a Process**

**CASE STUDY**

**Mr. D, a 64-Year-Old Man with Severe Abdominal Pain**

The interdisciplinary palliative care consultation team (PCT) was asked by the general internal medicine service to see Mr. D, a 62-year-old man who presented to the emergency room with uncontrollable severe abdominal pain. The patient reported several weeks of anorexia and a 15-pound unintentional weight loss. After a laparotomy and liver biopsy, he was found to have a large pancreatic mass, which was positive for adenocarcinoma and multiple peritoneal metastases. Within 24 hours after diagnosis, the medical team placed concurrent palliative care and oncology consultations. The former requested the need for assistance with uncontrollable pain, symptom management, prognosis/diagnosis explanation, and safe and appropriate discharge; the latter requested identification of anticancer treatment options.

The palliative care team’s initial assessment revealed that the patient was a retired train operator who lived with his wife. He had two sons who lived within 15 minutes of his home. He had no religious affiliation but identified himself as spiritual and accepted visits from the PCT pastoral care provider. Mr. D’s goals were to be free of pain, to be ambulatory, and to go home as soon as possible, so he could finish working on a project he had started for his youngest son’s wedding, three months hence. Comprehensive pain assessment revealed constant, gnawing, vague pain with an intensity score of 2 on a pain scale of 0 to 10. His personal goal for pain relief was a score of 0. Mr. D’s pain medication regimen was adjusted by the PCT nurse practitioner to provide pain relief at his tolerable level.

In addition, the PCT organized a patient/family meeting the next day. The meeting was held in the patient’s room so that he could participate in the discussions. In attendance from the family were the patient, his wife, and both of his sons. The PCT physician, social worker, nurse practitioner, and a nurse practitioner student were also present. Discussion included the patient’s understanding of his diagnosis, prognosis, and the influence and meaning of the disease on his goals of care. Advance directives, health care proxy, and a plan for long-term care at home after discharge were also discussed.

The next day, the patient chose his oldest son as his health care proxy, and his pain was in control under the new regimen. A smooth transition was made to a home hospice agency by the PCT social worker. In addition, the patient decided to follow-up with the outpatient oncology clinic to consider anticancer treatment for symptom relief.

**Lessons Learned**

- Interdisciplinary PCT is effective in addressing patient/family needs.
- Mandated, ongoing pain assessment practices within the hospital setting supported the ability to rapidly determine a pain relief plan.
- Advance directives are best determined before an emergency or crisis situation occurs.
- Effective palliative care involves the patient and the family.
- Palliative care and disease-modifying treatments can be rendered concurrently.
- The palliative care team’s expertise in pain and symptom management can be helpful to the patient and family and to the primary medical team.

**CASE STUDY**

**Mr. F, a 75-Year-Old Man with Bilateral Hip Fractures**

Mr. F, a 75-year-old man, was admitted to the medical/surgical unit after a fall at home with bilateral hip fractures. He had undergone open reduction with internal fixation of his hips bilaterally. His past medical history was significant for metastatic lung cancer with bony involvement and chronic obstructive pulmonary disease. Postoperatively, he developed intermittent confusion, cough, and dyspnea. A chest radiograph revealed a right upper lobe infiltrate, and intravenous antibiotics, supportive oxygen therapy, nebulizer treatments, and close observation were instituted.

Mr. F’s respiratory status worsened, and he required increasing oxygen via nasal cannula and then via face mask. As his condition declined, he was asked by the intern if he would “like everything done for him.” He continuously nodded his head “Yes” to the question. Shortly after this “discussion,” Mr. F suffered a respiratory arrest, for which he received CPR, intubation, and mechanical ventilation. He was transferred to the intensive care unit (ICU) in critical condition. No family members could be identified to assist the medical team with decision-making.

While he was in the ICU, a Swan-Ganz catheter and central line were inserted, multiple daily blood draws were taken, and Mr. F was heavily sedated to prevent him from dislodging his tubes. His medical condition progressively deteriorated, and the medical and nursing staff became increasingly frustrated, feeling helpless and not knowing Mr. F’s goals of care. After multiple attempts, a neighbor was finally contacted who said he didn’t really know the patient well enough to understand what he may have wanted done at this point. After a 2-week ICU stay, Mr. F developed sepsis. Eventually, he died in the ICU.
Lessons Learned

- Discussion of advance directives should take place with patients when they have capacity and are not in crisis.
- Early introduction of palliative care specialists may help to clarify and document patients’ goals of care and pain/symptom management preferences.
- Medical and nursing staff education about advance directives, palliative care, and EOL issues can establish baseline competence levels.
- Lack of advance planning can result in health care provider frustration, fatigue, and moral distress.
- Unnecessary patient and staff suffering can be minimized if palliative care education and policies are in place to support patient identification of goals of care.

Both of these cases illustrate ways in which EOL care occurs in hospitals. Each case is followed by “Lessons Learned,” which summarize areas of palliative care exemplars and areas ripe for improvement. Table 42–3 outlines a high-level process of care that illustrates “typical” hospital-based EOL care similar to that described in the case of Mr. F. Areas for improvement (some of which were illustrated by the case of Mr. D) are suggested adjacent to the process steps. These issues and cases serve as a basis for the remaining discussion of ways in which hospitals can create care systems that result in improved EOL outcomes for patients requiring hospital-based care.

Avoiding Hospitalized Death

Perhaps one of the most important ways to improve hospital-based palliative care is to develop other infrastructures of care outside the hospital, so that alternatives to inpatient admission at EOL exist. Alternatives such as home hospice care or skilled hospice care within assisted-living centers, free-standing hospices, or specially designated areas in nursing homes or rehabilitation facilities can provide expert palliative and hospice care at the EOL. However, many areas of the United States lack these sorts of options. For instance, in some rural areas, health care services such as visiting nurses or home care are sparse or unprepared to care for people who require intensive EOL care. Some visiting nurse and home care agencies may see so few symptomatic persons at the EOL that it is difficult to maintain adequate palliative care and hospice expertise in these agencies.

To improve the care that nonhospital systems provide, it is imperative that these organizations provide sufficient and appropriate education and training for their staff about the care possibilities at EOL. Organizations should encourage staff

- Patient dies in preferred site of death  
- Bereavement care offered to family after the death |
members to participate in conferences on EOL and palliative care and also should support them through the continuing education process (e.g., becoming certified in a specialty). Both the nursing and medical professions have embraced the concept of further EOL education and certification. The End-of-Life Nursing Education Consortium (ELNEC) and Education for Physicians on End-of-Life Care (EPEC) are examples of this approach for nursing and medicine, respectively.

The lack of hospice and palliative care expertise outside the hospital can be compounded by another very real problem, reimbursement for out-of-hospital EOL care. This problem must be viewed in the context of the Medicare hospice benefit, which in 2004 provided a standard per diem rate of $118.08 for routine home care; $689.18/day or $28.72/hour for continuous care during a crisis to maintain a patient at home; $122.15/day for up to 5 days of respite care; and $525.28/day for hospital, skilled, or freestanding inpatient hospice care for symptom management. These amounts are intended to cover all care needs, including nursing, home health aids, other discipline visits, pharmaceuticals, and medical equipment. For many patients eligible for Medicare hospice care, effective palliative interventions for symptom management (e.g., radiation therapy, chemotherapy, higher-priced supportive care medications for nausea and pain) are costly, given the reimbursement rate. Hence, patients who could otherwise benefit from hospice care are delayed in accessing the benefit until all of the aforementioned palliative treatments have been applied.

It is therefore not only an issue of patient identification, but also one of finance, that is responsible for late hospice referrals. Quality improvement efforts directed at improving EOL care by encouraging earlier referrals to the Medicare hospice benefit that ignore the financial issues are likely to fail. Agencies that place patients on the Medicare benefit despite ongoing expensive treatments are likely to find themselves in a state of financial instability.

Another barrier that must be overcome to realize lower in-hospital death rates is that of home care provision in the current culture of single-parent and two-parent working families. Currently, 75% of women work outside the home, yet they are often the ones called upon to provide care for ailing family members. When patients are enrolled in the Medicare hospice benefit, it is assumed that a family member or other person will be with the patient every day and that hospice staff will visit intermittently. For symptomatic or very ill patients, a family member may need to take a leave of absence or risk jeopardizing employment to provide adequate coverage for home care. Providing EOL care to a family member for an extended period can result in out-of-pocket medical expenses and lost income from both the patient and the caregiver, creating significant financial burdens. In these cases, a “reimbursable” hospital stay may be the only choice for family respite. The Last Acts Workplace Task Force has prepared a report of an employer survey and a set of model activities designed to help caregivers and their families with ill or dependent relatives in need of workplace supports.

Another mechanism to prevent hospital admissions is to develop a system that allows for early identification of patients who are eligible for palliative care and/or hospice care and to identify alternatives to hospitalization in the long-term EOL care plan. Early identification can take place at the beginning of the disease trajectory or at the point of a hospital admission. A good example of putting this concept into practice was illustrated in the first case study in this chapter, that of Mr. D. As soon as the patient was admitted to the hospital and a life-limiting illness was diagnosed, concurrent palliative care and oncology consultation requests were placed.

Early recognition of patients who are eligible for palliative care and prompt referral to experts in the field is a vital step in the process of integrating effective palliative care into hospital care. Putting prospective screening mechanisms in place can reduce the number and type of hospital admissions for palliative care. For instance, consider the situation of discharging a patient with adequate relief of pain but no long-term plan for dealing with worsening disease and increased pain. In this case, neglecting the bigger problem of long-term pain management only postpones the problem until a later date, when pain is likely to increase and the only available solution will be readmission. In addition to creating a long-term plan for already-hospitalized patients, prehospitalization programs that identify elders at home or in nursing homes who do not wish to have their conditions treated in a hospital can preclude undesired admissions.

The Patient Self-Determination Act (PSDA) of 1991 requires that hospitals and other organizations receiving Medicare or Medicaid funding provide written information to patients about their rights to make decisions accepting or refusing medical care. Further, it stipulates that advance directives, including living wills and appointment of a health care proxy, may be used to provide substituted judgment in the event of patients’ inability to speak for themselves regarding health care decisions. On the surface, this legislation appeared to be an infrastructure to improve EOL care in hospitals. Theoretically, patients would outline their preferences for certain types of treatments in a document or through a proxy to guide health care providers. For several reasons, however, this legislation has had little impact in defining the type of care received by hospitalized patients. Unfortunately, not all patients actually choose to complete advance directives; the documents apply only if the patients are incapacitated; they may not be specific enough to address the situation in which patients find themselves; and, when they do exist, the health care provider may not be aware of them, or the health care proxy may not interpret them as the patient intended.

Under the Patient Self-Determination Act, institutions are required to ask patients whether they have advance directives and then provide the appropriate information about them. The Act does not stipulate who in the health care agency is to give this information to patients and their families. Often, inexperienced personnel distribute the information without providing appropriate explanation of the documents, leading to lack of completion by patients.

In the second case study, that of Mr. F, there was no evidence of advance care planning before the patient’s hospital
admission. In this example, the topic of advance directives was introduced too late and inappropriately during the patient’s hospitalization. The patient was experiencing respiratory distress and was asked if he “would like everything done” for him. If the topic had been discussed earlier in his admission and he had been provided with comprehensive information regarding his prognosis and probable course of illness, the outcome may have been different. Improving and avoiding hospitalized death requires earlier discussions between patients and their providers regarding the diagnosis and prognosis and intensive health care provider education on the skill of communicating bad news and discussion of CPR.

Recent research and improvement efforts have attempted to study this phenomenon and improve the availability of such information and the consistency between patients’ stated preferences and the actual care administered. Incorporating such endeavors into quality improvement activities has the potential to influence hospital-based EOL care. An encouraging finding in one chart review of deaths of hospitalized patients indicated an increased implementation of comfort care in patients at the EOL in the minority of patients who had specified a proxy decision-maker, compared with those who had not specified anyone.

Innovative approaches to avoiding unnecessary hospitalization or other undesired care at the EOL are being tested through the Robert Wood Johnson (RWJ) Initiative Promoting Excellence in End of Life Care. (A full description of this program and the specific projects of the grantees is available on the Last Acts website, http://www.edc.org/lastacts/, accessed February 1, 2005.) In demonstration projects, strategies designed to move the knowledge and decision-making about palliative care options earlier in the course of illness than is currently the norm were tested. Four comprehensive cancer centers attempted to integrate palliative care options and approaches at the time of diagnosis of life-threatening, poor-prognosis cancers such as of the lung.

One example, Project ENABLE (Educate, Nurture, Advise Before Life Ends), identified and enrolled all patients with incurable lung cancer, advanced gastrointestinal malignancies, and metastatic or recurrent breast cancers at the time of diagnosis into a program that emphasized palliative care options. The program provided nurse coordination, prospective standardization of symptom assessment, and an educational curriculum that focused on topics of empowerment for patient and family decision-making and communication. Unlike the nurse coordinator of the SUPPORT study, these advanced practice nurses (and nurse practitioners) were members of the oncology care team and provided non-threatening, expert intervention that had prospectively garnered the support and sanction of the care team. This collaborative approach emphasized shared ownership of the process and, to date, seems to have been successful in influencing and shaping the care trajectory for this population.

Because of the success of the ENABLE project, Dartmouth-Hitchcock Medical Center (DHMC), funded by the National Cancer Institute (NCI), developed a randomized clinical trial, ENABLE II, to test the effectiveness of an intervention to improve quality of life for people with newly diagnosed metastatic or recurrent breast, lung, and gastrointestinal cancers. The intervention was designed to enhance the care that patients already receive at DHMC through nurse educator sessions and Shared Medical Appointments (SMAs) with a palliative care physician and nurse practitioner. The nurse educators in this study are available for resource allocation, education, and care coordination. Patient caregivers are encouraged to participate in the discussions with the patient and the nurse educator. It is hypothesized that, with the addition of the nurse educator and the availability of the SMAs, patients will have an enhanced quality of life and care consistent with their values and preferences.

The first case study, that of Mr. D, demonstrated the importance of early identification of patients so that advance directives and patient/family-centered care could be planned. The introduction of palliative care at the time of diagnosis allowed for appropriate and effective utilization of the palliative care services. If a patient is identified early in the course of illness, the palliative care team can act as a resource, or consultant, to the medical team. At this time, the palliative care specialists can provide information about good symptom and pain management and help with psychosocial issues that may arise. As the patient nears death, and the goal of care becomes focused more on comfort, the palliative care team becomes more prominent in caring for the individual and the family.

Many states laws have provisions for patients at home who are dying and do not want to be resuscitated to use home labeling systems such as a “DNR bracelet,” sticker, or forms. Specific details can be obtained in a 138-page report that details the results of a national survey conducted in 1999 of state laws and protocols providing for “do-not-resuscitate” (DNR) orders effective in nonhospital settings. In New Hampshire, before the DNR bracelet for home use was adopted, emergency medical technicians were required to begin resuscitation and transport the patient to a hospital, even if it was clear that this was not the patient’s wish. Often, despite teaching, the family faced with a dying loved one panicked as breathing became labored, heart rate slowed or stopped, or bleeding ensued. Even if documents such as living wills and durable powers of attorney for health care were produced, this did not release the emergency medical technicians of the responsibilities of response. In conjunction with New Hampshire Emergency Medical Services, a procedure was developed for outpatients and prehospital care personnel to indicate patient preferences for no emergency care if cardiopulmonary arrest occurs outside the hospital. The DNR bracelet, which looks similar to a typical green hospital bracelet except that it is blue, can be obtained from a local hospital on completion of specific paperwork. In the event of cardiopulmonary arrest at home or in an emergency department, this bracelet releases the responders from providing emergency care other than comfort care, symptom relief, and family support.

Finally, despite the development of nonhospital sites of EOL care, one analysis concluded that the main impetus behind hospital death is the number of hospital beds available in a referral area. This study suggested that, regardless of the availability of
out-of-hospital alternatives, hospital deaths will continue at a higher rate in areas that have abundant hospital beds available than in those areas with fewer beds. Since that report was published, another study from Oregon, which has had the lowest in-hospital death rate in the United States (31%), identified factors that facilitate arrangements for death to occur outside the hospital.35 Many of the factors already mentioned were found to be significant in the Oregon study, as evidenced by the following quotation: “For Oregon, it seems that economic forces and trends, coupled with an array of end-of-life resources, foster an environment in which patients and families more often obtain care during the last days of life in the setting they prefer.”35

**Models of Hospital-Based Palliative Care**

Promoting palliative care in the acute care hospital requires a myriad of resources. Depending on the model of palliative care being introduced, the required resources can vary greatly. For example, some changes may require financial support via construction or addition of staff, whereas other changes are less resource intensive. Regardless of the hospital and the availability of resources, all health care practitioners have the ability to introduce palliative care concepts and use already established resources to develop or improve their palliative care program. According to von Gunten, "One way that patients and their families will get better care is to ensure that clinical services focusing on the relief of suffering are available in every hospital" (p. 876). He suggested that hospitals consider their mission and level of palliative care delivery—as for other medical specialties (e.g., primary, secondary, tertiary)—and incorporate a model of palliative care resources in accordance with that level.

Primary palliative care refers to a level of care whereby basic skills and competencies are required of all physicians, nurses, and other health care practitioners. All practitioners should be competent at this level. Providers can gain the knowledge, attitudes, and skills needed to provide palliative care to their patients through basic training and clinical practice. Training such as the EPEC and ELNEC programs can provide comprehensive education that is needed at a minimum level.36 Both educational programs are discussed in more detail later in this chapter.

Secondary palliative care refers to a model in which all providers have a minimum level of competence and in addition have specialists who provide palliative care through consultation services or specialty unit care (or both). The development and success of the consultation team, in most instances, is guided with the training and expertise of hospice organizations.8 It is not necessary for the team to evaluate every patient with palliative care needs who is admitted to the hospital, but these specially trained clinicians are available as a resource and guide for their colleagues.

Additionally, major teaching hospitals and academic centers with teams of experts in palliative care are classified as tertiary organizations. A tertiary-level practitioner serves as the consultant to the primary and secondary levels in difficult clinical situations. Practitioners and institutions involved at the tertiary level of palliative care are also involved in educational and research activities.37 It is the responsibility of all hospitals and health care organizations to be competent, at a minimum, at the primary level of palliative care. However, regardless of level, different components of care may be incorporated into the model; some are less resource intense (e.g., care pathways), and others may require additional allocations of budget and personnel. The various levels of hospital-based palliative care and their components are described in greater detail in the following sections.

**Primary Palliative Care**

Primary palliative care should be available at all hospitals. This level of care requires a minimum of provider education in basics of pain and symptom management. The JCAHO has identified minimum standards that should be present (see later discussion). Additionally, in April 2004, The National Consensus Project for Palliative Care released Clinical Practice Guidelines for Quality Palliative Care. The guidelines, which can be downloaded free of charge from their website (http://www.nationalconsensusproject.org, accessed February 1, 2005), represent a consensus of five major United States palliative care organizations: the American Academy of Hospice and Palliative Medicine, the Center to Advance Palliative Care (CAPC), the Hospice and Palliative Nurses Association, the Last Acts Partnership, and the National Hospice and Palliative Care Organization. The guidelines identify core precepts and structures of clinical palliative care programs. Domains of palliative care from the guidelines are listed in Table 42–4. The domains can serve as a framework for hospitals to develop and evaluate their approach to a comprehensive palliative care program.

Medical and Nursing Education: A Key Component of Primary Palliative Care

The majority of students in medical, nursing, and other health care disciplines receive clinical training for practice in hospitals. Until recently, with the shift to ambulatory care, the majority of medical and nursing student education was provided in the hospital setting. However, few hospitals provided role models for teaching palliative care practices. The following is one of several comments made by family members about the insensitive way the act of “pronouncing” the death of their loved one was handled by house staff:

I was holding his hand when he stopped breathing. I called the nurse who called the doctor. He went over and looked at him lying in the bed, listened for a heartbeat with his stethoscope and said, “He’s dead,” and walked out of the room. That’s it, not “I’m sorry,” no “Is there anything we can do?” just “He’s dead.” It was painful—and made us think that the staff didn’t care.

It is not surprising that this death occurred at the beginning of July, when interns began their first rotations directly out of medical school. A study by Ferris and colleagues documented that medical schools devote little time to care of dying patients. A survey of medical interns revealed significant concern and fear about providing these services with no or little supervision. Lacking role models, the traditional “See one, do one, teach one” supervisory principle of medical education was ineffective. One resident explained that the pronouncing experience was not one that was perceived as causing harm when performed by the inexperienced. Another stated, “I felt really inadequate, I had absolutely no idea what to do when the nurse called me to pronounce this patient whom I had never met—my first night on call. I was never taught the steps—how long should I listen to the chest to be sure there was no heartbeat; what, if anything else, I should do; what should I say to the family. Thankfully, the death coordinator was there to help me fill out the paperwork.” Conversely, in states where nurses are allowed to pronounce deaths, some course work exists to teach a process that gives attention to the family.

Clearly, such a predictable and easily defined process is amenable to quality improvement if it is identified as an educational priority for an institution or health care provider. A sample pocket card developed from multiple data sources of such a project is shown in Figure 42-2. This is printed internally on brightly colored stock on a standard laser printer so that it can be easily modified and so that quantities are readily available. A similar card was developed by others as part of a multimedia packet for resident education, called the Art of Compassionate Death Notification. Other components of this comprehensive program include a facilitator’s guide, manuals for learners, and videos demonstrating communication skills.

The problem is further compounded by the lack of EOL content in student curricula and major textbooks. These sources have been analyzed and have been found sorely lacking in the content that would inform students about the basics of EOL symptom management, decision-making, and critical communication skills. Until recently, neither textbooks nor clinical experiences were available to provide critical guidance to health professionals in how to provide effective EOL care. On a positive note however, funding is becoming available to study the issue and develop solutions.

The introduction of programs in nursing and physician education has provided an important resource in education regarding EOL principles of care. The ELNEC program is partly sponsored by the American Association of Colleges of Nursing. The program is discussed in further detail in Chapter 60, but in brief, it is a curriculum developed to train nurse educators to provide undergraduate and graduate nursing students and practicing nurses with EOL education. The American Medical Association (AMA) and the RWJ Foundation have developed EPEC, a program that addresses similar issues for physicians. Both curricula are widely available as means to educate nursing and medical staff.

Lastly, nurses have developed a number of other initiatives to advance professional knowledge and competency in EOL care. The American Nurses Credentialing Center (ANCC) administered the first palliative care advance practice nurse certification examination in May 2003. Since the development of the examination, hundreds of advance practice nurses, both nurse practitioners and clinical nurse specialists, have become nationally board certified as palliative care specialists.

Chapter 60 discusses the topic of nursing education in detail. For the purposes of this chapter, it is important to remember to involve students in the process of palliative care education and change. Improvements in hospitals should address the learning environments of students. Specific ideas for improving the interface between education and quality improvement of hospital-based palliative care include the following:

- Arrange for clinician role models to provide lectures to students and faculty.
- Assist with curriculum review of current EOL care training.
- Change elective coursework and clinical work in hospice and palliative care to required status, and include these subjects in other mandatory clinical assignments.
- Use texts that contain clinically relevant palliative care content.
- Include content on ambulatory-based symptom management and decision-making that defines patient preferences for care.
- Encourage students to describe evidence-based approaches to palliative care and to challenge their mentors about approaches and interventions that increase the burden of care without clear patient benefit.
- Encourage students to learn from staff role models appropriate ways of communicating bad news and of presenting options that respect patient preferences and values.
Identify opportunities for undergraduate or graduate fellowships in palliative care.

As part of quality improvement teams, offer students opportunities to become data collectors from patients, charts, and staff.

**Palliative Care Pathways, Standards, and Aggressive Comfort Treatment**

Reducing variation is a major strategy used by quality improvement leaders. Variation refers to the fluctuations in a process that can result in delays or unpredictable outcomes. A patient with a serious illness who is experiencing an acute crisis may follow many different paths. Numerous institutions have studied their current processes of care and have created clinical pathways that can help standardize procedures and reduce the variation of care experienced by terminally ill or symptomatic palliative care patients as they traverse the complex health care system. Usual components include attention to patient symptoms as well as family needs at system entry and throughout the course of stay until discharge.

Assigning time frames to address needs helps in monitoring progress and tracking outcomes that have been met, as well as those that continue to need attention.

Although published guidelines and standards may offer similar suggestions, the road map format of clinical pathways identifies practical and accountable mechanisms to keep patient care moving in the direction of specific identified outcomes. Some pathway forms allow for documentation of variation from the designated path. Analysis of several instances of variation might alert a care team about a potential system “defect” in need of improvement. Additionally, Figure 42–3 illustrates a sample form for a brief, practical, but informative chart review that can be used to evaluate care of patients who died in a hospital environment.

Many institutions have implemented standard orders or evidence-based algorithms to guide various aspects of care pertinent to EOL situations. Some of these include limitations of certain types of therapies such as CPR and blood pressure medications. In addition, preprinted order sheets that outline management of symptoms and side effects such as nausea, constipation, and pain are making it easier for physicians and trainees to reproduce comprehensive plans that do not vary because of individual opinion. These order forms can be valuable teaching tools in a setting of regularly changing care providers. Figure 42–4 shows a sample order sheet and the companion guidelines printed on the reverse for patients who are hospitalized and have a palliative focus of care. Certainly, important considerations in the development of such “recipes” for care include having broad, multidisciplinary, evidence-based input. The process of producing such documents is also potentially a care consensus and learning environment for many teams.

It is perhaps one of the greatest misconceptions that once a person no longer seeks curative treatment “there is nothing more to do.” Palliative care is aggressive care directed at comfort. All practitioners are responsible to ensure that, when cure is no longer possible, the patient and family can have confidence that everything will be done to provide pain management and relief of suffering. It is particularly important for health care providers to be cognizant of this fact when caring for individuals in the hospital at the EOL. Nurses in particular can advocate through development of hospital policy, education, and individual practice for aggressive comfort care. The health care team must ensure that a positive approach—focusing on what can be done for dying patients and their families—is implemented.

**Hospital-Based Bereavement Programs**

Improving the quality of EOL care in hospitals does not end with the development of mechanisms to ensure peaceful, pain-free patient death. Although accomplishing this goal is surely a comfort to family and friends, the aftermath for survivors is an important final step in the process of EOL care. Which families are most in need of specific services? Identifying families at the greatest risk has been the topic of palliative

Guidelines for Comfort Measures Orders

D/C ALL PREVIOUS ORDERS- Assess & reorder existing orders effective for comfort.

Activity: Goal is patient comfort. Activity level and hygiene routine should be based on patient’s preference.

Hunger: Goal is to respond to patient’s hunger, to not maintain a “normal nutritional intake.”

Thirst: Goal is to respond to patient’s thirst which is best accomplished by oral fluids, sips, ice chips, and mouthcare per patient desires, not IV hydration.

IV Fluids: Goal is to avoid over-hydration which can lead to discomfort from edema, pulmonary, and gastric secretions, and urinary incontinence. A small volume of IV fluid may assist with medication metabolism and delirium.

Dyspnea: Respond to the patient’s perception of breathlessness rather than “numerical abnormalities” i.e. oxygen saturation via pulse oximetry. Interventions include medications (e.g. opioids, antianxiety agents, steroids), scopolamine patch and minimizing IV fluids to decrease secretions; oxygen therapy per nasai cannula prn for patient comfort-avoid face mask.

Fans at Bedside – Fans are available for patient comfort and are often more effective for perception of breathlessness than other interventions.

Elimination: Focus on managing distress from bowel or bladder incontinence. Insert Foley Catheter prn – per patient comfort and desire.

Oral Care: Studies show dry mouth is the most common & distressing symptom in conscious patients at end of life. Ice chips and sips of fluid prn; Humidify oxygen to minimize oral/nasal drying.

Mouth care q 2 hours prn – sponge oral mucosa and apply lubricant to lips and oral mucosa

Skin Care: Air mattress, Pressure Sore Prevention Measures: per DHMC skin care guidelines.

Incontinent care every 2 hours and prn.

Monitoring: Focus monitoring on the patient’s symptoms (e.g. pain) & responses to comfort measures.

Psychosocial Consults: Goal is to provide resources and support through the dying process

Dyspnea Management: consider opioids, scopolamine patch, atropine for secretions

Anxiety/Agitation Management: consider combination of lorazepam (Ativan) & haloperidol (Haldol).

Myoclonus: consider benzodiazepines &/or opioid rotation for myoclonus.

Depression Management: evaluate for antidepressants or methylphenidate.

Sleep Disturbance Management: consider diphenhydramine (Benadryl).

Pruritus Management: consider diphenhydramine (Benadryl) PO/FV.

Fever Management: consider acetaminophen (Tylenol) PO rectal

Nausea/Vomiting Management: consider prochlorperazine (Compazine), metoclopramide; 5-HT3 antagonist PO/FV.

Constipation Management: consider Narcotic Bowel Orders.

Diarrhea Management: consider diphenoxylate/atropine (Lomotil) or loperamide (Imodium).

care research, particularly in evaluating the quality of palliative care services.

Bereavement for survivors is an important part of the total care plan after the patient’s death (see Chapter 27). Adverse physical and psychological outcomes of unsupported grief are known to occur during the bereavement period. Because of this, bereavement services are a typical component of the services offered to families when patients die as part of a hospice program. Because only 10% of all deaths in the United States have hospice involvement in EOL care, a large portion of families must rely on follow-up offered by other care providers. Few hospitals routinely offer bereavement services to families after patient deaths in hospital.

Evaluation of services during the bereavement period serves two main purposes in quality improvement. First, development of these services by hospitals can address currently unmet needs of survivors, who usually need to discuss their own needs for information and support in order to cope with the loss. Second, this is a time when hospitals can learn more about the effectiveness of their provision of EOL care from the families’ perspectives, both what went well and what can be improved. For instance, results of a focus group of bereaved family members indicated that, although the family was quite satisfied with pain management, breathing changes and dyspnea were not anticipated and were very distressing. Another institution determined from a bereavement survey that the institution needed to make improvements in the areas of respecting patient privacy and dignity, family communications, emergency care, advance directives, and bereavement support. See Appendix 42–1 for an example of a questionnaire with which family members can evaluate the EOL care received by their loved one.

After evaluation, hospitals can develop a project to improve and standardize bereavement care and would be well advised to consult with a local hospice program to collaborate on how this might occur. Instituting some very simple, standardized responses to death can vastly improve family satisfaction with care. These actions might include sending a note of sympathy or establishing some other contact from a staff member, mailing a list of local bereavement resources or a pamphlet, and delaying the time before a hospital bill is mailed out to prevent its coinciding with funeral or memorial services.

### Secondary and Tertiary Palliative Care

As described previously, some hospitals are able to go beyond minimum palliative care competency and develop additional resources to provide palliative care services. Interdisciplinary consultation teams and units are commonly available to provide more specialized care. A tertiary center also focuses on educating students, developing curricula, performing research that can enhance the evidence base for palliative care, and serving as a role model for other programs. As described later, the AHA has begun to collect data on the number of hospital-based “palliative care programs”; however, these programs can vary, from volunteer personnel focusing on palliative care, to multicomponent programs with many staff and a mission of service, research, and education.

### Palliative Care Consultation Teams

A growing literature summarizes the development of palliative care teams within hospitals to offer specialized consultation and expertise to patients, families, and other health care providers. Dunlop and Hockley published a manual in 1990 and a second edition in 1998 describing the experience in England. They described the movement as one that tries to take the hospice philosophy of care and bring it into the hospital using a consultancy team. More recently, U.S. and Canadian hospital-based teams have described their experiences. Among the components of successful teams are an interdisciplinary approach, strong nursing leadership, physician and nonphysician referral, rapid response to requested consultation, around-the-clock availability, and ability to follow patients through all care settings.

From a quality improvement perspective, these teams can be effective in modeling behaviors that are supportive of appropriate hospital-based palliative care, but they should also recommend infrastructure changes as part of their approach to consultation. For assessment of care and processes to improve, demographic statistics about the location and nature of regular consultations is needed. For instance, if a particular unit or care provider has regular difficulty managing patients with dyspnea, targeted educational approaches and treatment algorithms or standardized orders may help achieve consistent and long-lasting change. Theoretically, a consultancy team could “put itself out of business” with such an approach. However, teams to date have not reported the need to dissolve as an outcome of implementing system changes.

Few studies have examined the impact of a consultation team on the overall care of patients at the EOL. Challenges have included identifying exactly which components or processes of the team are responsible for the outcomes, performing multimethod research (e.g., using both qualitative and quantitative methods) defining outcomes attributable to team intervention, and implementing measures that can validly and reliably capture this information. Establishing an evidence base is paramount to the economic justification and reimbursement mechanisms for many hospitals.

### Inpatient Hospice and Palliative Care Units in a General Hospital

Some hospitals, faced with the problem of providing high-quality EOL care in the acute care hospital, have found the development of a specialized unit to be the solution. In the United Kingdom, these units have been developed from preexisting oncology units, as part of another unit, or sometimes in a separate building that is distinct but near the hospital it serves. U.S. hospitals have varying amounts of experience with opening specialized units for the care of patients with
EOL, hospice, or palliative care needs. This in-hospital approach has some general benefits and burdens. Some of the benefits include the following:

- Patients requiring palliative care have a familiar place to go during the exacerbations and remissions that come with progressive disease.
- Unit staff and policies are under the control and financing of experts trained as a team who are skillful at difficult care and communications.
- Patients may get palliative care earlier if other care teams see the advantages of this approach and trust that patients will receive good care.
- Providers who monitor their patients on these units (if allowed) can learn valuable lessons about palliative care that can be carried forward to future patients. These future patients may not require admission to the PCU for some types of care.

Some of the disadvantages of creating a distinct unit include the following:

- It can prevent others from learning valuable palliative care techniques if the principal staff are seen as "specialized" and are secluded in one area.
- Care providers may come to rely on this expertise instead of learning palliative care techniques themselves.
- If unit transfer includes a transfer of doctors to a palliative care specialist, patients and families may feel abandoned by their primary team in the final hours.
- Hospice providers fear loss of the hospice philosophy when a PCU exists in the context of the general hospital.

Some mature palliative care programs have been able to provide a trinity of services, including a consultancy team, an inpatient palliative care/hospice unit, and a home care program, all under the jurisdiction of a single hospital system. This full-service approach can ease transitions among different levels of care and has the potential to provide the optimum in seamless care for patients at the EOL. Such programs can serve as models and can set standards for other programs to aim for.

A major consideration in the use of such services, regardless of how broadly based, is the barrier to care presented by not recognizing that a patient is dying. Many studies now document health care providers’ inaccuracy in predicting prognosis. As a result, many patients who could benefit from palliative care and hospice services are denied admission. A comprehensive discussion of the reasons for inaccuracy of prognosis is beyond the scope of this chapter, although it remains a major issue that must be addressed within any institution wishing to develop specialty palliative care services. Hospice programs are very familiar with such issues, and palliative care programs would be wise to review lessons learned in providing hospice care earlier in the disease trajectory for patients in need.

### Initiatives to Improve Hospital-Based Palliative Care

In 1974, the Royal Victoria Hospital in Montreal, Canada, developed one of the first initiatives in North America to improve hospital-based palliative care. They developed a palliative care service to meet the needs of hospitalized patients who were terminally ill within the general hospital setting. The palliative care service was an integral part of the Royal Victoria Hospital, a 1000 bed teaching hospital affiliated with McGill University, and consisted of five complementary clinical components: (1) the PCU, (2) the home care service, (3) the consultation team, (4) the palliative care clinic, and (5) the bereavement follow-up program. Members of an interdisciplinary team were involved with the care of these patients, and the focus was on holistic care with pain control and symptom management.

These basic palliative care concepts are still not prevalent in many U.S. hospitals. However, positive changes are occurring, as evidenced by data from the AHA, which began to measure hospital-based palliative care in 2000. Table 42–5 summarizes the 2000–2002 AHA survey data on the growth of hospital-based palliative care, hospice, and pain management programs.

institutional assessment of the quality of pain management.67 These tools can be easily adapted to help a project team think more broadly about palliative care and symptoms in addition to pain.68 This section describes other examples of resources for developing or improving hospital-based systems of palliative care.

Center to Advance Palliative Care

One of the major efforts to improve hospital-based palliative care programs in the United States is led by the CAPC. Formed and funded by a 4-year grant from the RWJ Foundation in 2000, the national center was established at Mount Sinai School of Medicine in New York City. The Center, codirected by Christine Cassel, MD, and Diane Meier, MD, has a mission to make information on how to establish high-quality palliative care services available to hospitals and health systems nationwide.69

CAPC assists hospitals with the planning, development, and implementation of hospital-based palliative care programs. In addition to assisting hospitals and other health systems in program development, CAPC facilitates collaboration among hospitals, hospices, and nursing homes; promotes educational initiatives in palliative care; and encourages growth and development of new and innovative mechanisms for financing palliative care programs.69

CAPC has developed six Palliative Care Leadership Centers (PCLCs) to assist organizations that wish to learn the practical aspects of developing a palliative care program. The six organizations are Fairview Health Services, Minneapolis, MN; Massey Cancer Center of Virginia Commonwealth University Medical Center, Richmond, VA; Medical College of Wisconsin, Milwaukee, WI; Mount Carmel Health System, Columbus, OH; Palliative Care Center of the Bluegrass, Lexington, KY; and University of California, San Francisco, CA. Each represents a different type of health care system and palliative care delivery model. They serve as exemplar organizations offering site visits, hands-on training, and technical assistance to support development of palliative care programs nationwide. Further information regarding the PCLC can be found on the CAPC website70 (http://www.capc.org, accessed February 1, 2005).

Institute for Healthcare Improvement

In 1997, a quality improvement organization known as the Institute for Healthcare Improvement (IHI) adopted improving EOL care in hospitals and other parts of the health care system as a major mission. As shown in Table 42–6, the structure of the first IHI EOL collaborative and the results of this initiative have been published.14,26 In brief, the organization provided quality improvement assistance to organizations, and the resulting methods and results constitute a wide variety of outcomes to which almost any hospital or health care agency might aspire.

To assist groups in getting started, a table (Table 42–7) focused on four major issues in EOL care was distributed to encourage organizations to compare their problems and issues (“current practice”) with what were proposed as “best” and “optimum” practices. The table included examples of specific, measurable target outcomes that a group might choose to adopt.26 The four selected areas resulted from brainstorming by the planning group, who were all nationally recognized leaders and clinicians in EOL care. They concluded that the following four areas were most in need of attention and amenable to change:

- Improving the management of pain and other symptoms
- Continuity of care
- Advance directives
- Family support

Each institution sent a team of at least two or more members, representing the key disciplines implementing change in their organizations (e.g., nurses, physicians, chaplains, social workers, administrators) to a series of three meetings between July 1997 and July 1998. Steps to ensure support from senior leaders of each organization were considered vital at the outset. Teams were provided with large-group didactic content and written materials. They also participated in concentrated, small-group meetings to identify what they would do on return to their institutions. Regular progress reports were sent to IHI, monthly conference calls were held, and online discussions were conducted to support the teams and offer advice if particular barriers or issues developed.

These teams were successful in achieving many of their goals, from improving pain relief and dyspnea, reducing hospitalizations, and improving advance care planning, to implementing bereavement services. The experiences of these organizations provide a wealth of practical advice and methods for accomplishing quality improvement in many areas and settings of care and are available on the IHI website (http://www.ihi.org/ihi, accessed February 1, 2005) and in print. Breakthrough improvements achieved by the collaborative are listed in Table 42–8.

In 2003, the IHI, together with the Center for Palliative Care Studies (CPCS), developed a new collaborative focusing on adapting health care systems to meet the challenges of serious chronic illness in the last phase of life. The key goal of the collaborative is to gather information and create a common database that will be used to help improve the dying experience for patients and their families.27 By participating in this collaborative, organizations have the ability to

- Improve quality of life for people with serious illnesses
- Decrease hospital length of stay
- Enhance use of hospice services
- Meet JCAHO standards
- Build new palliative care programs
- Learn methods to apply quality improvement to real problems
**Table 42-6**
Structure of the Institute for Healthcare Improvement (IHI) Collaborative: Improving Care at the End of Life*

The Institute for Healthcare Improvement (IHI) is a Boston-based, independent, nonprofit organization working since 1991 to accelerate improvement in health care systems in the United States, Canada, and Europe by fostering collaboration, rather than competition, among health care organizations.

IHI provides bridges connecting people and organizations that are committed to real health care reform and who believe they can accomplish more by working together than they can separately.

**Background**

Study after study finds that patients, families, doctors, and other professionals want the same qualities of care at the end of life: dignity, comfort, communication, and the company of loved ones. Yet time and again we seem trapped in desperate struggles and wasted energies that help no one. Rational, respectful care at the end of life is possible; now we need to assure it.

**Participants**

Since July 1997, 48 organizations from throughout the United States and Canada have been working intensively to improve the quality of care at the end of life while also reducing unwanted, nonbeneficial care.

**Overall Goals**
Reduce incidence of severe pain by 25%.

Increase by 35% the number of patients who have made their wishes known about end-of-life care.

Reduce by 50% the number of patients with transfers in the last 2 weeks of life.

**Areas of Focus**

Collaborative teams are focusing on the following areas for improving care at the end of life:

- Pain management and palliative care
- Advance care planning for end of life
- Optimizing transfers among care settings
- Family support.

**Key Changes**

Successful interventions that improve care at the end of life for patients and their families include the following:

- Instituting pain and symptom management protocols.
- Initiating advanced care planning discussions within 24 hours after admission and documenting the plan in a patient's chart. If this is not done, someone other than the patient’s physician initiates advanced care planning within 36 hours after admission.
- Increasing 24-hour access to staff, using pagers and other communication devices to decrease hospital emergency room utilization.
- Using a “pull-system”—one-to-one case finding in the hospital to arrange early admission of targeted patients to palliative and hospice care.
- Beginning bereavement assistance and support for the family and friends before the patient dies.

<tr>
<td><strong>Pain/Symptoms</strong></td>
<td><strong>100% assessment on a regular, recurrent basis (e.g., “fifth vital sign” or item in nursing home quarterly review)</strong></td>
<td><strong>100% assessment of pain, depression, dyspnea, and anxiety on appropriate schedule (admission, change in status, and periodically)</strong></td>
<td>1. Ensure 100% compliance with recurrent assessment protocol.</td>
</tr>
<tr>
<td>• Most often not assessed/monitored</td>
<td>• WHO/APS/AHCPR guidelines for cancer pain</td>
<td>• Use of all appropriate modalities, often on time-limited trials—including opioids, biofeedback, hypnosis, steroids, neuroablative procedures, stimulants, etc. Severe symptoms always have an appropriately aggressive response</td>
<td>2. Guarantee initial assessment of serious pain or dyspnea within 5 min in hospital, 15 min in nursing home or at home; initial intervention within 15 min in hospital and 1 h in nursing home or at home.</td>
</tr>
<tr>
<td>• Routinely treated with predictably inadequate treatment (drugs and dosages)</td>
<td>• Low rate of use of opioids for breakthrough pain; all opioids on regular dosing</td>
<td>• Ready availability of skilled consultants in all settings (including ICU, hospital, nursing home, and home).</td>
<td>3. All patients have pain &lt;5 (of 10) in last 2 days of life (by patient or family report).</td>
</tr>
<tr>
<td>• Usually treated only after established, rather than preventively</td>
<td>• Patients or families in control of dose timing</td>
<td>• Patient and family have expectations of competence, control, comfort and are enabled to be active participants in deciding and providing care</td>
<td>4. Reduce by 50% the number of patients who report pain &gt;5 (of 10) in any time period or episode of care.</td>
</tr>
<tr>
<td>• Gaps and delays in treatment are agonizing and commonplace</td>
<td>• Coverage doses travel with patient to procedures or during transfers</td>
<td>• Patient never left suffering due to relocation</td>
<td>5. All cancer patients with pain &gt;5 (of 10) are on appropriate opioids, and all patients with pain &gt;5 (of 10) are on appropriate analgesics.</td>
</tr>
<tr>
<td>• Major symptoms are treatable: pain, dyspnea, depression, anxiety (also nausea, itching, insomnia)</td>
<td>• Serious symptoms considered appropriate for emergency response (stat page, rapid home visit, calling on back-up provider)</td>
<td>• Emergency response “on call” for serious symptoms in any setting</td>
<td>6. All patients at risk of severe dyspnea have “standby” plans and needed skills/supplies in place (also advanced care planning goal).</td>
</tr>
<tr>
<td>• No one held accountable for shortcomings</td>
<td>• Performance routinely reviewed and shortcomings addressed</td>
<td>• Routine care review and routine system feedback for quality improvement, public education, and accreditation</td>
<td>7. Resource people with proven skills in chronic pain management and in management of neuropsychiatric complications of serious illness (depression, psychosis, delirium, anxiety, seizures) are readily available to every patient regardless of setting or insurance.</td>
</tr>
<tr>
<td>• Patients and families expect severe symptoms</td>
<td>• Patients and families expect comfort</td>
<td></td>
<td>8. Eliminate times when patient or family reports pain as being overwhelming or out of control.</td>
</tr>

<tbody>
<tr>
<td><strong>Continuity/Transfers</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Seriously ill persons have no one who stays with them throughout.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Transfers between settings are dictated mostly by utilization and financing issues for the care system, not patient or family preferences.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Transfers among professionals are dictated by professionals’ convenience.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Most patients change settings and/or caregivers multiple times in the last few weeks of life.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• The fact and the expectation of discontinuity precludes intimacy, empathy, promise-making, and trust.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Many transfers lose settled care plans, treatment schedules, and understandings.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Frequent transfers mean that no one is held accountable for the overall course—or even for there being a standard for a good course.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Transfer to hospice or nursing home is especially discontinuous, and transfer by EMS is routinely maximally life-extending.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Hospice usually ensures continuity in all settings, once enrolled.</td>
<td>• People dying with cancer, advanced old age, or dementia virtually always die where they live. Services are mobilized to these settings.</td>
<td>10. All patients/families understand the patient’s symptoms and management and can adjust medications within agreed range.</td>
<td></td>
</tr>
<tr>
<td>• Some nursing homes have developed capacity to care for seriously ill residents on-site, including a hospice-like mode.</td>
<td>• People dying with strokes and organ system failures die at home (or nursing home) or in a hospital, but in either case under the care of those who know them and with appropriate services.</td>
<td>11. All patients with signs of depression have a trial of drug treatment.</td>
<td></td>
</tr>
<tr>
<td>• Some special “advanced illness” programs coordinate all care out of one office and keep one nurse/social worker/physician in charge of care throughout.</td>
<td>• Utilization-induced transfer almost never happens in the last 2 days of life.</td>
<td>12. Individual and regular shortcomings are noted and reviewed in Incident Reports, M&amp;M conferences, QI committee, and credentials review.</td>
<td></td>
</tr>
<tr>
<td>• Some programs have coordinated records available at all sites electronically, or have the patient carry the record, or both.</td>
<td>• Switching key personnel while a patient is in any one setting is uncommon, viewed as unfortunate, and the subject of careful planning to support patient and family.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Some nursing home or home care agencies have arranged for special direct hospital or hospice admission to avoid trauma in ambulances and ERs.</td>
<td>• Patients dying in ICU, ER, or busy ward settings have more family-attentive settings available for temporary use.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Some states and regions have developed accord on orders that reshape EMS services.</td>
<td></td>
<td></td>
<td></td>
</tr>

**Advanced Care Planning**

- Very little attention is paid to overall future course—not discussed, articulated, or planned for.
- Most people are not even asked to name a surrogate, even when who that would be is quite unclear.
- Among persons who have very little chance of surviving CPR and substantial chance of cardiopulmonary arrest, few have discussions about DNR, even when put at special risk by being in hospital.
- Most legal advance directives are too nonspecific, unavailable, or inapplicable to direct care, yet patients think they have solved their problems by filling them out.
- Almost no care planning deals with the specific drugs, skills, or procedures needed to allow the patient’s preferences to be effected.
- Some specific documented patient preferences are thoughtlessly abrogated.

- Regularly offering formal written planning opportunities (e.g., Vermont Ethics Network form)
- Area-wide advance planning
- Emergency kit of drugs and other paraphernalia at home, appropriate to family training and professional availability
- Emergency response team to go to home for pain, dyspnea, seizures, family crisis, etc.
- Formatted advance planning discussions

<tr>
<td>• Families are excluded or ignored, granted only the role of veto in care planning.</td>
<td>• Care in hospice routinely includes family and spiritual concerns.</td>
<td>• Center the experience in terms of spirituality and meaning, rather than medical and physiologic issues.</td>
<td>10. 80% of “last phase of life” patients at home have plans documented to shape 911/EMS response.</td>
</tr>
<tr>
<td>• Families do not know prognosis, uncertainties, desirable timing of behaviors, who to turn to for counsel, or what is reasonably expected of them.</td>
<td>• Hospice and home care agencies sometimes provide brochures and counseling about what to expect and how one might respond.</td>
<td>• Make human relationships and spiritual issues the central concern, with professional caregiver habits always subservient.</td>
<td></td>
</tr>
<tr>
<td>• Many opportunities to complete relationship (human or transcendent) are not taken.</td>
<td>• Hospice and some individual programs routinely follow families in bereavement, providing or referring to services as appropriate.</td>
<td>• Use episodes of serious illness as “dress rehearsals” for eventual death.</td>
<td></td>
</tr>
<tr>
<td>• Many patients or families do not have opportunity to attend to religious/spiritual issues or meaningful rituals.</td>
<td>• Some care providers insist on enabling family cohesion and rearrangement, spiritual search for meaning, and culturally meaningful rituals.</td>
<td>• Create rituals that mark stages and ensure reassurance.</td>
<td></td>
</tr>
<tr>
<td>• Most families have no follow-up in bereavement.</td>
<td>• Some care settings help patients and families “rehearse” for dying by practicing leave-taking and imagining the time after.</td>
<td>• Always follow up with family—explain, reassure, counsel.</td>
<td></td>
</tr>
<tr>
<td>• Many dissatisfied or guilt-ridden families are never heard, and some have lives blighted by their experience.</td>
<td>• Families and patients have little practice at leave-taking.</td>
<td>• Learn how to provide care that is death accepting/enhancing, life-prolonging, and physiology-restoring.</td>
<td></td>
</tr>

These two breakthrough series collaboratives have provided resources to hospitals interested in improving EOL care. By participating in the latest collaborative, organizations can expect participation in team learning sessions on improving the quality of care for serious illnesses, telephone and e-mail consultation and feedback from collaborative faculty, and involvement in the improvement process, keeping up with best practices, and mobilizing support for needed changes.71

Veterans Health Administration Initiatives

The U.S. Department of Veterans Affairs (VA) health care system has shown leadership in improving EOL care in their hospitals through multiple initiatives that have been designed or implemented since the early 1990s. In 1992, Secretary Jesse Brown mandated that VA medical centers (VAMCs) establish hospice consultation teams to respond to the complex palliative care needs of patients with advanced disease. The VA provided training for team members during 1992 and 1993. One team reported success in pain and cost reduction while also undertaking significant institution-wide improvements through education of nurses and house staff and making pain management resources available.72

In 1997, the Veterans Health Administration began an intensive, system-wide, continuous quality improvement (CQI) initiative to improve pain management. This endeavor resulted from a 1997 survey that found both acute and chronic pain management services to be inconsistent, inaccessible, and nonuniform throughout the system. Two major thrusts formed the basis of the initiative: issuing a system-wide mandate and forming a permanent National Pain Advisory Committee to provide direction and encouragement to the development of the program. Thus, this initiative incorporated two essential elements found in all successful system-wide improvement strategies: an influential champion at the highest level of the organization and a mandate for organizational commitment to this activity. The charge document offered a variety of suggestions for system improvement: making pain more visible by enhancing current measurement and reporting methods (using the “Fifth Vital Sign” approach in all patient contacts in the system); increasing access to pain therapy and increasing professional education about pain; adopting the Agency for Health Care Policy and Research and American Pain Society guidelines for pain management; pursuing research on pain therapies for veterans; distributing and sharing pain management protocols via a central clearinghouse; and exploring methods to maintain cost-effective pain therapy.

Also in 1997, the VA incorporated a palliative care measure in the performance criteria of its regional directors. In this program, performance of the directors is evaluated based on the number of charts that contain information about veterans’ preferences regarding various palliative care indicators.73

In 1998, the RWJ Foundation Last Acts program created a Clinical Palliative Care Faculty leadership program and awarded a 2-year grant to promote development of 10 faculty fellows from VA-affiliated internal medicine training programs. Their goal was to develop curricula to train residents in the care of dying patients, to integrate relevant content into the curricula of residency training programs, and to add internal medicine faculty leaders and innovators to the field of palliative medicine.

In 2001, the VA Hospice and Palliative Care initiative began. This was a two-phase initiative to improve EOL care for veterans. Phase 1 of the project was funded in part by the National Hospice and Palliative Care Organization (NHPCO) and the Center for Advanced Illness Coordinated Care. This phase of the initiative was designed to accelerate access to hospice and palliative care for veterans. A major product of the program was the Hospice-Veteran Partnership Toolkit. It also created 2.5 full-time equivalent employee positions in Geriatrics and Extended Care, to be used for hospice and palliative care presence in the VA system.

In 2004, phase 2 of the project was launched. It was funded in part by Rallying Points and the NHPCO. It builds on the success of phase 1 and aspires to develop a Hospice-Veterans Administration Partnership in every state and to build an enduring infrastructure for the Accelerated Administrative and Clinical Training Program. In a statement made in 2002 regarding the VA national initiatives, the VA made a clear commitment to improving hospice and palliative care for their patients. The Geriatrics and Long Term Care strategic plan is as follows74: “All VAMCs will be required to have designated inpatient beds for hospice and palliative care, or access to these services in the community, and an active hospice and palliative care team for consult, care and placement.” Together these initiatives address the need for improvement on multiple fronts and create a momentum in the VA system that can set an example for other large hospital-based systems of care.

Table 42–8
Breakthrough Improvements Achieved in Past CPCS-Led Collaboratives

- 60% reduction in patients with pain greater than 5 on a 10-point scale
- 50% or greater decrease in exacerbations in heart or lung failure
- 90% or greater rates of documented discussion and planning in advance of emergency or incompetence
- Substantial increases in hospice length of stay
- Substantial decline in use of artificial feeding in advanced dementia

United Hospital Fund’s Hospital Palliative Care Initiative

The multiyear, multihospital research and demonstration initiative of the United Hospital Fund (UHF) sought to improve the quality of hospital care for persons at the EOL. In the first phase of the initiative, 12 hospitals received grants to analyze the institutional, professional, fiscal, and regulatory forces shaping EOL care. In the second phase, 2-year program grants were awarded to the following five New York City hospitals to seek specific goals:

1. Beth Israel Medical Center—To develop an array of new palliative care service delivery and education activities, including the creation of a new position, medical director for palliative care.
2. The Brooklyn Hospital Center—To create a new position of palliative care expert, with responsibility and authority to facilitate the coordinated delivery of palliative care services to a select group of patients and their families.
3. Montefiore Medical Center—To evaluate and improve physician practice patterns concerning EOL care by using evaluative feedback for a 1-year period, focused on five areas of EOL care.
4. The Mount Sinai Medical Center—To create a comprehensive new supportive care service to provide coordinated palliative care services across a range of settings.
5. Saint Vincent’s Hospital and Medical Center—To create a new palliative care consulting team to build on the existing outpatient supportive care service and expand them to include physician and psychiatric expertise for a select group of patients and their families in both the inpatient and outpatient settings.

Although not all of these organizations are specifically using quality improvement methods, the outcomes and products to improve palliative care that evolved from these projects can inform other hospitals wishing to replicate their successes.75

Since the implementation of the five programs, the UHF has produced a special report, Building Hospital Palliative Care Programs: Lessons from the Field. This report can be obtained from the UHF website (http://www.uhfnyc.org/, accessed February 1, 2005) or by calling the organization directly. A major outcome of the initiative was recognition by all involved of the complexity and obstacles to integrating palliative care into hospital systems. Table 42–9 lists the lessons learned from the five-hospital palliative care initiatives and the suggestions for hospitals that are creating palliative care programs in the future.

The Joint Commission on Accreditation of Healthcare Organizations

The JCAHO is one of the paramount accreditation organizations for hospitals and other health care organizations. The purpose of JCAHO is to continuously improve the safety and quality of care provided to the public. JCAHO is an independent, not-for-profit organization, and perhaps its most important benefit is that JCAHO-accredited organizations make a commitment to continuous improvement in patient care. During an accreditation survey, the JCAHO evaluates a group’s performance by using a set of standards that cross eight functional areas: (1) rights, responsibilities, and ethics; (2) leadership; (3) education and communication; (4) health promotion and disease prevention; (5) health care delivery; (6) management of human resources; (7) management of information; (8) improving network performance.

In 2004, a specific palliative care focus was introduced within two standards: (1) rights, responsibilities, and ethics and (2) the provision of care, treatment, and services. The goal of the ethics, rights, and responsibilities standard is to improve outcomes by recognizing and respecting the rights of each patient and working in an ethical manner. Care, treatment, and services are to be provided in a way that respects the person and fosters dignity. The performance standard states that a patient’s family should be involved in the care, treatment, and services if the patient desires. Care, treatment, and services are provided

<tr>
<td>Lessons learned from five-hospital palliative care initiatives:</td>
<td></td>
</tr>
<tr>
<td>• There is no one successful model of palliative care services.</td>
<td></td>
</tr>
<tr>
<td>• Initiating palliative care services is extraordinarily demanding of staff time and other resources.</td>
<td></td>
</tr>
<tr>
<td>• A key decision is how much authority the palliative care team will have to implement its recommendations after the initial referral.</td>
<td></td>
</tr>
<tr>
<td>• Initial resistance among senior primary care physicians should not be underestimated.</td>
<td></td>
</tr>
<tr>
<td>• Palliative care teams may make most of their contributions by establishing goals of care, addressing family needs, and resolving conflicts.</td>
<td></td>
</tr>
<tr>
<td>• Key departments and their directors must be included early in the planning process.</td>
<td></td>
</tr>
<tr>
<td>• It is important to trace the impact on overall hospital and functioning.</td>
<td></td>
</tr>
<tr>
<td>• Discharge planning is key to a successful palliative care effort.</td>
<td></td>
</tr>
<tr>
<td>• Palliative care services in hospitals are costly and resource demanding.</td>
<td></td>
</tr>
</tbody>
</table>

Next Steps:

• Reach patients earlier in course of illness through the Community Oriented Palliative Care Initiative
• Introduction of palliative care in combination with life-prolonging care
• Provide wider range of services to patients and families
• Decrease the inappropriate use of palliative care service

through ongoing assessments of care; meeting the patient’s needs; and either successfully discharging the patient or providing referral or transfer of the patient for continuing care.\textsuperscript{77,78} More detailed information is available by contacting JCAHO or visiting their website at http://www.jcaho.org (accessed February 1, 2005).

The revisions of these standards in 2003 and 2004 incorporated a stronger emphasis on palliative care practices within hospitals. Hence, organizations are being held accountable for the manner in which they provide appropriate palliative care. It is in the public’s best interest that JCAHO requires organizations to adhere to these provisions for a successful accreditation. The implementation of specific EOL standards has reinforced the directive that pain and EOL issues must be addressed and health care institutions should strive to maximize performance activities that affect the quality of patient care in this population.

\textit{Economic Issues of Hospital-Based Palliative Care}

The use of the diagnosis-related group (DRG) system has played a major role in the current provision of hospital-based care. The prospective payment system of Medicare was one of the first economic stimuli that began to shift EOL care out of hospitals. Simultaneously, the Medicare hospice benefit was instituted, which reconfigured financing for hospice care (described earlier) and reimbursed some home care, acute care, and specialized units in nursing homes.\textsuperscript{15} The Health Care Financing Administration (HCFA) uses DRG codes to define Medicare reimbursement, although at present limited mechanisms exist to obtain reimbursement for various types of palliative care in hospitals under Medicare. In response to this limitation, in October 1996 a trial of using the v code 66.7 was initiated as a mechanism to collect data about palliative care being provided in hospitals.\textsuperscript{79} At present, this code does not elicit reimbursement but allows for data to be collected about the current nature of palliative care.

Clinicians and administrators may see development of palliative care services as a way to save money as less invasive procedures and tests are recommended, compared with more expensive “curative” care. An evaluation of a high-volume specialty unit and team was able to demonstrate cost savings via cost avoidance in one center. Smith and colleagues\textsuperscript{40} evaluated 237 patients housed on the PCU compared with 38 contemporary control patients treated elsewhere in the hospital and determined that PCU patient charges were 59% lower, direct costs 56% lower, and total costs 7% lower. In this case, providing less unwanted care resulted in fewer ICU stays and fewer costly, invasive procedures. However palliative care experts suggest that programs often “rationalize” the use of hospital resources in a way that respects patients’ preferences for care. In program development, financial risk–benefit analysis is critical; through CAPC and other resources, tools to assist hospitals wishing to perform such analyses are available.\textsuperscript{17}

Although there is a bias against hospital death, because hospital care is associated with high-technology interventions, there are times when dying in the hospital allows for a more comfortable death than at home. In any case, valid reimbursed hospital admissions for palliative care may be difficult to obtain within the current DRG codes. In the best case, the palliative care DRG would remedy this. However, some oppose the creation of a new DRG, because the assignment of the code may only describe what is currently being done, which may not be adequate and hence may not reflect what state-of-the-art palliative care could achieve.

Managed care can influence the quality of EOL care in hospitals in both positive and negative ways. Patients in a managed care plan need approvals and are carefully observed so that they do not spend unnecessary days in the hospital. This approach can be quite restrictive when extra planning time to ensure patient comfort is restricted. On the other hand, several features of managed care make it a potentially positive force for improvement.\textsuperscript{81} Anthem Blue Cross and Blue Shield of New Hampshire has implemented an innovative Advanced Disease Care Management approach. In response to identified needs of members, the director of medical management and the clinical quality improvement coordinator (both nurses) redesigned the plan’s hospice benefit.\textsuperscript{82} Excerpts from the provider/member educational brochure describing their program are shown in Table 42–10. Standards of pain and hospice care were sent to all providers, and a monitoring system was implemented to ensure adherence and to provide for review of situations that were outside the scope of the guidelines. This use of quality improvement methodology outside the hospital to simplify care and hold providers and insurers accountable for a predetermined standard of EOL care proved successful. The approach ultimately benefited plan members by increasing access to appropriate levels of palliative care (including hospital-based care, when appropriate).

Another effort to evaluate how health plans and systems provide EOL care consists of a strategy to measure and compare outcomes across organizations. Funded by the RWJ Foundation in 1997, the Foundation for Accountability (FACCT) assembled an expert panel of EOL clinicians, quality improvement specialists, research scientists, and health plan administrators and held focus groups of high-risk patients to develop a strategy to measure the quality of EOL care in health plans. The intent was to allow for comparisons of plan performance and to help health plans set goals for quality improvement activities at the EOL.\textsuperscript{83} The report summarizes distinctions between measures for public accountability and quality improvement, consumer opinion about what is important at the EOL, and important measures and reporting categories for capturing plan performance in eight areas of care within three major categories: steps to good care, results of care, and experience and satisfaction with care. In addition, practical advice about the measurement process and additional areas of needed research are described.\textsuperscript{83}

Future Directions

The first and biggest step in improving hospital-based palliative care is to reduce the number of unnecessary acute care in-hospital deaths. Because death in hospitals will never be completely eliminated, the second biggest improvement will come as a result of improved communication among the health team, patient, and family. Strategies can be put into place to identify the goals of hospital care and implement a prompt, effective, holistic plan to meet predetermined values and preferences.

A number of features of hospitals actually make it easier to employ successful full-scale improvements, including the amount of readily available data and regulatory efforts such as those of the JCAHO. Innovations such as palliative care consultation teams, services, units, and pathways have already begun to provide successful models for improvement. A recent study comparing the cost and quality of care for terminally ill patients in PCUs versus regular hospital settings found that patients received better care in these specialized units that also proved to be cost-effective. This example provides a strong case for dedicating specific hospital units and teams to the palliative care population.80

Sometimes a disadvantage can really be an advantage. For example, the perceived endless paperwork, rigidity, and regulations common to hospitals may be among the biggest advantages to making improvements in hospital-based EOL care. Extensive and readily accessible databases of variables that reflect the quality of EOL care are available and are the positive side of monumental documentation requirements. Because of this accessibility, the study of the quality of EOL care in hospitals and some areas of quality improvement have been brought to light relatively rapidly, plans for change have been implemented, and results have been monitored. In the context of hospital oversight and regulation, medical professionals have much more control over hospital operations than can ever be expected in the community or home. Improvement of pain relief and palliative care in hospitals is likely to experience a boon under current JCAHO standards.

One of the recommendations of the Institute of Medicine is that all future health care providers and all current practitioners must receive EOL care education.2 Numerous efforts are being put forth by the medical and nursing communities to provide EOL care and palliative care education for practicing and future nurses and physicians, some of which were discussed in detail earlier in this chapter. Also, the ANCC, in conjunction with the National Board for Certification of Hospice and Palliative Nurses (NBCHPN) and support from New York University, has developed the first advanced practice nursing certification in the specialty of palliative care.47 However, all health care professionals need to possess a minimum level of palliative care knowledge in order to provide the most effective primary palliative care to patients and their families.

The good news is that there is a growing foundation of resources to assist the clinician or team wishing to apply a quality improvement process to hospital-based EOL care. However, such abundance may overwhelm the beginning clinician, quality improvement personnel, or project team. A mantra from an unknown source on the cover of one quality improvement manual65 lends heart—"We cannot do everything at once, but we must do something at once." A few key sources provided throughout the chapter describe quality improvement projects, groups, and contacts. Palliative care as a developing specialty lacks an adequate evidence base.44 However, as more research findings become available, the rapid-cycle improvement infrastructure is one way to quickly test and translate findings into clinical practice. Although funding mechanisms exist for research, fewer funding opportunities exist for quality improvement.

Quality improvement in hospitals has the potential to provide a significant foundation on which to build a larger health care system and culture of humane care at the EOL. Dr. Christine Cassel provides a simple guideline for success in the preface to the National Academy of Sciences Institute of Medicine report entitled Approaching Death: Improving Care at the End of Life:2:

Dartmouth-Hitchcock Medical Center Care at the End of Life Questionnaire

Please answer the following questions about your loved one’s care during their last hospitalization by putting a check mark next to the response which best describes your opinion. If the question is about something that did not apply to your loved one’s last hospitalization, please check the “Does not apply” option. Feel free to use the “Comments” section to give details about your experience that would help us understand your response.

Questions #1-5 are about the care your loved one and your family received.

1. The staff providing care did so in a thoughtful and sensitive manner.
   
   ___________ Strongly agree ___________ Agree ___________ Disagree ___________ Strongly disagree
   ___________ Does not apply

   Comments: ________________________________________________
   ________________________________________________
   ________________________________________________

2. We felt that the doctors and nurses did all they could to carry out the wishes of our loved one and family.

   ___________ Strongly agree ___________ Agree ___________ Disagree ___________ Strongly disagree
   ___________ Does not apply

   Comments: ________________________________________________
   ________________________________________________
   ________________________________________________

3. We had enough privacy and space to comfortably stay with our loved one during the last hours of life.

   ___________ Strongly agree ___________ Agree ___________ Disagree ___________ Strongly disagree
   ___________ Does not apply

   Comments: ________________________________________________
   ________________________________________________
   ________________________________________________

4. Staff helped to meet our family’s needs in a caring and sensitive manner at the time of death.

   ___________ Strongly agree ___________ Agree ___________ Disagree ___________ Strongly disagree
   ___________ Does not apply

   Comments: ________________________________________________
   ________________________________________________
   ________________________________________________

5. We felt supported after our loved one’s death.

   ___________ Strongly agree ___________ Agree ___________ Disagree ___________ Strongly disagree
   ___________ Does not apply

   Comments: ________________________________________________
   ________________________________________________
   ________________________________________________

Questions #6-8 are about pain control. If your loved one did not experience pain during their last hospitalization, please skip to question #9.

6. Our loved one’s pain was well controlled prior to their death.

   ___________ Strongly agree ___________ Agree ___________ Disagree ___________ Strongly disagree
   ___________ Does not apply

   Comments: ________________________________________________
   ________________________________________________
   ________________________________________________

7. The staff responded quickly to our loved one’s needs for pain relief.

   ___________ Strongly agree ___________ Agree ___________ Disagree ___________ Strongly disagree
   ___________ Does not apply

   Comments: ________________________________________________
   ________________________________________________
   ________________________________________________

8. There was an acceptable balance between pain relief and side effects of the medication such as drowsiness and/or confusion.

   ___________ Strongly agree ___________ Agree ___________ Disagree ___________ Strongly disagree
   ___________ Does not apply

   Comments: ________________________________________________
   ________________________________________________
   ________________________________________________
Questions 9-10 are about breathing difficulties. If your loved one did not have breathing difficulties during their last hospitalization, please skip to question 11.

9. We were satisfied with the care provided for our loved one's breathing difficulty.
   - Strongly agree  
   - Agree  
   - Disagree  
   - Strongly disagree  
   - Does not apply  
   Comments:  

10. We received enough information about changes in breathing to understand what was happening.
   - Strongly agree  
   - Agree  
   - Disagree  
   - Strongly disagree  
   - Does not apply  
   Comments:  

Questions 11-15 are about communication.

11. We felt there was good communication between:
   The doctors at Mary Hitchcock Memorial Hospital and us.
   - Strongly agree  
   - Agree  
   - Disagree  
   - Strongly disagree  
   - Does not apply  
   
   The nurses at Mary Hitchcock Memorial Hospital and us.
   - Strongly agree  
   - Agree  
   - Disagree  
   - Strongly disagree  
   - Does not apply  
   
   The doctors and nurses at Mary Hitchcock Memorial Hospital.
   - Strongly agree  
   - Agree  
   - Disagree  
   - Strongly disagree  
   - Does not apply  
   
   The doctors at Mary Hitchcock Memorial Hospital and our loved one's local doctor.
   - Strongly agree  
   - Agree  
   - Disagree  
   - Strongly disagree  
   - Does not apply  
   Comments:  

12. We received consistent information about our loved one's condition (reason for hospitalization) and what to expect.
   - Strongly agree  
   - Agree  
   - Disagree  
   - Strongly disagree  
   - Does not apply  
   Comments:  

13. We felt well informed about what was happening during the last hospitalization prior to death.
   - Strongly agree  
   - Agree  
   - Disagree  
   - Strongly disagree  
   - Does not apply  
   Comments:  

14. We received the information we needed to move forward with funeral arrangements.
   - Strongly agree  
   - Agree  
   - Disagree  
   - Strongly disagree  
   - Does not apply  
   Comments:  

15. Overall, how would you rate the care that your loved one and your family received during their last hospitalization? (1 = the worst possible care and 10 = the best possible care). Please circle one. 
   1 2 3 4 5 6 7 8 9 10

Please feel free to share any additional comments you may have regarding your loved one's care prior to death. Also, please comment if you have suggestions on how we might improve care to future patients in the hospital who are at their end of life.
This page intentionally left blank
An intensive care unit (ICU) is, by tradition, the setting in which the most aggressive care is rendered to hospitalized patients. Patients are admitted to an ICU so that health professionals can perform minute-to-minute titration of care. The primary goals of this aggressive care are patient resuscitation, stabilization, and recovery from the acute phase of an illness or injury. However, many patients die in ICUs. It is estimated that 540,000 people die after admission to ICUs in the United States each year. Stated otherwise, almost one in five Americans receives ICU services before death. ICU deaths account for 59% of all hospital deaths and 80% of all terminal inpatient costs. One third of patients with metastatic cancer who die in hospitals do so in ICUs, as do 88% of patients with acute myocardial infarctions. Therefore, it is clear that management of the process of dying is common in ICUs.

In the high-technology environment of an ICU, it may be difficult for health professionals and families of dying patients to acknowledge that there are limits to the effectiveness of medical care. However, it is important to focus on providing the type of care that is appropriate for the individual patient and the patient’s family, be it aggressive lifesaving care or palliative end-of-life care. This chapter discusses the provision of palliative care in ICUs. Specifically, challenges and barriers to providing such care in ICUs are described, and recommendations are offered for the provision of symptom assessment and management. Current issues related to withholding and withdrawing life-sustaining therapies are covered. Recommendations are offered for attending to the needs of families as well as health care providers who care for ICU patients at the end of life. Finally, an international agenda for improving end-of-life care in ICUs is presented.
The Limitations of End-of-Life Care in Intensive Care Units

Although many deaths occur in ICUs, an ICU is rarely the place that one would choose to die.\(^4\) Health professionals in ICUs, frequently uncertain about whether a patient will live or die, are caught between the opposing goals of preserving life and preparing the patient and family for death. It is important for professionals to realize that a patient’s death is not necessarily an indication of ineffective care. Yet, there are serious limitations to the care provided to seriously ill and dying patients and their families. Communication between physicians and patients may be poor; physicians often may not implement patients’ refusals of interventions; patients may be overly optimistic about the outcomes of cardiopulmonary resuscitation (CPR); and many hospitalized patients die in moderate to severe pain and with other troubling symptoms.\(^5,6\)

In a landmark study, more than 5,000 seriously ill hospitalized patients or their family members were asked questions about the patients’ pain.\(^7\) Almost one-half of these patients had had pain during the previous 3 days, and almost 15% had had pain that was moderately or extremely severe and occurred at least half of the time. Of those with pain, 15% were dissatisfied with its control. Other distressing symptoms, such as fatigue, dyspnea, and dysphoria, have been reported by seriously ill and elderly hospitalized patients and their family members.\(^8\) Although patients with colon cancer had the most pain, many of the patients reporting pain had diagnoses that were not surgery or cancer related (e.g., chronic obstructive pulmonary disease, congestive heart failure). These findings stress the importance of attending to the assessment and management of pain and other symptoms in all ICU patients.

Planning Palliative Care for ICU Patients

Providing comfort to patients should accompany all ICU care, even during aggressive attempts to prolong life. However, if a patient is not expected to survive, the focus shifts to an emphasis on palliative care. It is often extremely difficult in an ICU to determine the appropriate time for a change of focus in care. A transition period occurs during which the health professionals, the patient’s family, and sometimes the patient recognize the appropriateness of withdrawing and/or withholding treatments and begin to make preparations for death. The transition period (i.e., the time from decision to death) may be a matter of minutes or hours, as in the case of a patient who has sustained massive motor vehicle injuries; or it may be a matter of weeks, as in the case of a patient who has undergone bone marrow transplantation and has multiple negative sequelae while in the ICU. Clearly, this time difference must be recognized as a factor that can influence the experience of a patient’s family members. When patients rapidly approach death, their family members may not have time to overcome the shock of the trauma and adjust to the possibility of death. On the other hand, when death is prolonged, family frustration and fatigue may be part of their experience. Health professionals who are sensitive to these different experiences can individualize their approaches and interventions for family members.

However, this transition from aggressive care to death preparation has not been well operationalized. Children who die in ICUs often do so after physician determination that death is imminent and after care has been restricted.\(^8\) The restrictions are usually equally divided among withholding resuscitation, limiting medical interventions in addition to withholding resuscitation, and withdrawing medical interventions.\(^5,9\) In a retrospective study of 300 pediatric patient deaths, the most common mode of death was active withdrawal of support.\(^9\) Usually, physicians raise the issue of restricting care (76% of the time), but sometimes it is the family that initiates these discussions (16% of the time).\(^9\) The unique interdependence between a child and family makes it essential and justifiable for the family to participate in treatment-related decisions\(^11\) during the transition period and throughout the dying process.

The transition period is clearly uncomfortable for many health care professionals. In fact, when scenarios concerning end-of-life decision-making in the absence of patient or family input were presented to more than 1,300 ICU staff, respondents were very confident of their choices less than 30% of the time.\(^12\) Physicians were more confident than nurses, who were more confident than house staff. Although some guidelines exist to assist ICU professionals through the processes of maintaining, limiting, or stopping life-sustaining treatments,\(^13\) there are no well-tested standards to assist in the decision-making process. It is important, therefore, for ICU professionals to consider the following steps when caring for patients at risk for not surviving their ICU course:

1. Identify and communicate the goals of care for the patient at least once a day. Ascertain whether the patient has developed an advance directive, whether a family member has durable power of attorney, and whether the patient has communicated a preference about CPR. Almost half of 960 seriously ill patients who wanted CPR withheld did not have a do-not-resuscitate (DNR) order written during their hospitalization, and almost one third died before discharge.\(^5\)

2. Outline the steps that need to be taken to accomplish the goals of care and evaluate their effectiveness. Technology should not drive the goals of care. Instead, technology should be used when necessary to accomplish the goals, and its use should be minimized when the primary goal is achievement of a peaceful death.

3. Use a multidisciplinary team approach to decision-making regarding transition to end-of-life care. All team members, including the patient’s family, should reach a consensus, sometimes through negotiation, that the withdrawal of life support and
a peaceful death are the appropriate patient outcomes.\(^4\)

4. Develop and communicate to professionals and family the palliative care plan, and identify the best persons for implementing the various actions in the plan. End-of-life treatment decisions are particularly complex when the dying patient is an infant or child.\(^2\) De Groot-Bollujt and Mourik\(^2\) provided specific suggestions for involving a child’s family members in the dying process. These included offering family members opportunities to participate in preparing the child to die and even holding the child during the dying process.

5. Developing a plan of care may include enlisting the assistance of in-hospital palliative care staff and/or hospice services. If feasible and desired by the family, consideration should be given to transfer of the adult or pediatric patient from the ICU to in-hospital support care services, such as those at Detroit Receiving Hospital.\(^5\) Or, if possible and desired, patients may be transferred to the home or to community hospice services. A major focus in any palliative care plan is on providing optimal symptom management.

Symptom Assessment and Management: An Essential Component of Palliative Care

Pain Assessment

Although pain was identified in the Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatments (SUPPORT) study as one of the most prevalent and distressing symptoms of seriously ill patients dying in large teaching hospitals,\(^1\) hospitalized patients continue to receive inadequate pain management.\(^7\) Pain research focusing on dying ICU patients remains scarce, but advances that have been made in the assessment of pain in other critically ill patient populations can be applied to dying patients.\(^1,2,3\) The patient’s self-report continues to be the most valuable indicator of pain.\(^2,9,11\) Simple numeric or word rating scales, word quality scales, and body outline diagrams may be offered to patients who are able to point to words, numbers, and figures. It is important to determine the quality, timing, and location of pain whenever possible, so that treatment may be guided by accurate information rather than assumptions. The specificity of the pain presentation guides the selection of optimal treatment interventions.

Often, critically ill patients are unable to self-report because of their disease process, technological treatment interventions (e.g., mechanical ventilation), or the effects of medications (e.g., opioids, benzodiazepines [BZDs]). The use of BZD infusions may make patients too sedated to respond to pain, although pain may still be present. On the other hand, the use of the anesthetic agent propofol or of neuromuscular blocking agents (NMBAs) such as vecuronium may limit or entirely mask the patient’s ability to express or show any behavioral signs of pain. It is essential that clinicians understand that propofol and NMBAs have no analgesic properties, even though visible signs of pain disappear during their use. If these agents are used, they must be accompanied by infusions of analgesics, sedatives, or both. In these situations, the nurse may enlist the assistance of family members or friends in their evaluation of the patient’s discomfort. The nurse can ask them about any chronic pain experienced by the patient or methods used by the patient at home to decrease pain or stress. This information can then be incorporated into the patient’s care plan.

If patients are unable to self-report, the nurse can use a structured, systematic method of pain assessment that includes observation of behavioral and physiological signs of pain. A pain assessment reference guide is one example of a bedside instrument that can assist professionals to perform a multidimensional pain assessment.\(^2,1\) A behavioral pain scale (BPS) has been developed that quantifies pain in sedated, mechanically ventilated patients.\(^3\) However, further work is necessary to confirm the validity of some of the pain parameters on the BPS (e.g., fighting ventilator) and the usefulness of the BPS in making analgesic decisions. Recently, certain behaviors were documented to be associated with procedural pain experienced by acutely or critically ill patients; these included grimacing, rigidity, wincing, shutting of eyes, verbalization, moaning, and clenching of fists.\(^2\) Patients with procedural pain were at least three times more likely to have increased behavioral responses than patients without procedural pain. These findings provide support to the assessment of specific pain behaviors in patients who are unable to self-report. However, behavioral measures are only proxies for the patient’s subjective reports, even though they are frequently the only measures available. As another proxy measure, nurses can use their imaginations to identify possible sources of pain by asking the question, “If I were this patient and had intact sensations, what might be making me uncomfortable?” Even if patients are not exhibiting behavioral or physiological signs of pain, it does not mean that they are pain free.

The comfort of 31 adult patients undergoing terminal weaning from mechanical ventilation was assessed by use of behavior observation and physiological measures.\(^2\) Moderate correlations \((r = 0.60; P = 0.001)\) found between the Bizek Agitation Scale (BAS)\(^2\) and the previously validated COMFORT scale\(^2\) suggested that these observational measures may be able to evaluate responses to pain, distress, or agitation in certain dying ICU patients. Correlations between electroencephalogram (EEG)-derived data, obtained through the use of a cerebral function monitor,\(^2\) and the BAS and COMFORT scales were \(r = 0.53\) and \(r = 0.58\), respectively \((P = 0.001)\). Findings from this study about behavior and physiological measures are preliminary at best. EEG data were derived from only 11 of the 31 patients, because the others had global anoxic encephalopathy. Furthermore, the specific origin or cause of “discomfort”
(e.g., pain, dysphoria) cannot be determined from such global measures. However, the findings show promise for the clinical usefulness of "comfort" assessment measures that can assist clinicians to assess pain and the effectiveness of treatment interventions at the end of life.

**Procedural Pain**

Before and during the transition from aggressive care to end-of-life care, critically ill patients undergo many diagnostic and treatment procedures. Many of these, such as central, arterial, and peripheral line placements, nasogastric tube placements, chest tube removal, and endotracheal suctioning, are quite painful and may be the primary cause of suffering at the end of life. Turning, one of the most ubiquitous procedures performed in acute and critical care settings, was shown to be the most painful of six commonly performed procedures. Other procedures that may be unnecessary, painful, and unpleasant include central line insertions, wound débridement, frequent dressing changes, and the use of sequential compression devices. Paice and colleagues demonstrated through a chart review that 71% to 100% of 57 patients in a medical ICU had numerous procedures during their last 48 hours of life. These procedures included intravenous (IV) medications and fluids, urinary catheters, antibiotics, x-ray studies, enteral feeding tubes, and ventilators. Nurses can act as "gatekeepers" by evaluating the appropriateness of procedures being planned for patients, especially after a decision has been made to end life support, and they can advocate for their omission. Helping patients avoid iatrogenic suffering is a fundamental part of palliative care. The most important procedures for patients to experience at the end of life are those that promote comfort. Yet, when necessary procedures must be performed, the nurse can facilitate pain management before and during procedures.

**Pharmacological Management of Pain**

Numerous categories of analgesics and types of modalities exist for administration to critically ill patients. As in all situations, the selection of analgesics should depend on the specific pain mechanism, and the route and modality should be matched to their predictability of effectiveness. Although no comprehensive survey of pain management techniques used for dying ICU patients has been reported, the most common analgesic intervention is IV opioids. Use of a continuous infusion of an opioid allows for titration of the drug to a level of analgesic effectiveness and for maintenance of steady plasma levels within a therapeutic range. Foley presented the following recommendations for the use of opioids in dying ICU patients: (1) choose a specific analgesic therapy on the basis of individual patient characteristics; (2) know the equianalgesic dosage of a drug and its route of administration; (3) choose the route of administration that is appropriate to the patients' needs; and (4) develop a dose titration protocol. In addition, health care professionals may consider the administration of intermittent opioid boluses for breakthrough pain.

Clearly, concerns about patients becoming tolerant of or dependent on opioids are misplaced during terminal care. What is important is that professionals recognize the development of tolerance, which is the need for larger doses of opioid analgesics to achieve the original effect, and increase the dosage as necessary. There is no ceiling effect from opioids; the dose can be increased until the desired effect is reached or intolerable side effects develop. If it is the family's wish to have the opioid infusion decreased in a sedated patient to assess that the patient is able to participate in end-of-life decision-making, this must be done slowly and carefully. Opioid-dependent patients are at high risk of developing withdrawal symptoms, which would seriously increase their discomfort. In this situation, physical dependence can be addressed by gradually lowering the opioid dose while carefully assessing for signs of pain or withdrawal.

Titration of analgesics to achieve the desired effect is one of the most challenging and important contributions that ICU nurses can make to the comfort care of dying patients. The desired effect can often be described as use of the least amount of medication necessary to achieve the greatest comfort along with the optimum level of tranquil awareness.

In ICU settings, concern may arise that administration of analgesics in the amounts necessary to provide comfort could “cause” death. It is essential that ICU health professionals understand the “double-effect” principle. In brief, the double-effect principle states that administration of analgesics to dying patients in the amounts necessary to decrease pain and suffering, although it might have the unintended consequence of hastening death, is a good, ethically sound way to treat a dying patient. This principle, framed in ethics, provides support to such an action when the clinician's moral intent is directed primarily at alleviating suffering rather than intending to kill. In a survey of 906 critical care nurses in the United States, almost all respondents (98%) agreed or strongly agreed with the double-effect principle.

**Nonpharmacological Management of Pain**

Nonpharmacological interventions for pain management complement, but do not substitute for, the use of pharmacological interventions. Numerous therapies may be used by critical care nurses to augment the administration of medications to promote patient comfort. They include the use of distraction (e.g., music, humor), relaxation techniques (e.g., visual imagery, rhythmic breathing), and massage. Even during occasions when the cognitive status of a somnolent ICU patient is uncertain, the patient can be provided information about activities being done to and around them. Family members can be encouraged to assist with the provision of comfort measures and may welcome this way of participating in care and decreasing their sense of helplessness. Family involvement is discussed in further detail in a later section of this chapter.
Anxiety, Agitation, and Sedation

An important part of palliative care in the ICU is assessment and treatment of anxiety and agitation. There are many reasons for a dying patient to be anxious or agitated, or both. Assessment of anxiety and agitation provides the practitioner with information that can guide the use of specific interventions.

Assessment of Anxiety and Agitation

Simple numeric rating scales for anxiety can be used if the patient can self-report to identify how much the patient is psychologically bothered. Critical care clinicians and patients are familiar with the use of the 0-to-10 numeric rating scales for pain. “Anxiety” word anchors can be substituted for pain word anchors so that the numeric rating scales also can be used to quantify the degree of distress.

Common behavioral or physiological signs of anxiety include trembling, restlessness, sweating, tachycardia, tachypnea, difficulty sleeping, and irritability. Several agitation/sedation assessment scales are available (e.g., Jacobi and colleagues). These scales can be printed on the patient flowsheet or on a separate form and used as a bedside assessment tool. Nurses can plan periodic and simultaneous assessments of pain using pain rating scales and agitation scales. The frequency with which the scales are used depends on the patient’s condition and the schedule for evaluating treatment interventions.

Pharmacological Management to Promote Sedation in Anxious or Agitated Patients

Along with opioids, other categories of sedating drugs are frequently used in the ICU, especially for patients who are mechanically ventilated. Several guidelines, algorithms, and review articles exist regarding the use of analgesics and

*Drug doses are general recommendations. Dosing should be individualized to a particular patient. Under usual circumstances, start with low doses, wait for effect, and titrate to desired effect.

sedatives. Often, the goal of combined analgesic-sedative therapy is to promote physical and psychological comfort. Practice decisions include choosing the right type and combination of medications; determining whether to use interrupted sedative infusions (which provide opportunities for patient assessment) or continuous infusions; determining appropriate clinical endpoints for pharmacological interventions; and evaluating the effectiveness of sedation protocols on practices and outcomes.42,43

The appropriate pharmacological agent to control agitation and anxiety is selected according to the desired effect. For example, uncomplicated anxiety is best treated with BZDs, whereas paranoia, panic, and fear accompanied by delusions and hallucinations may require the addition of antipsychotic agents. BZDs are excellent agents for anxiolysis, but they possess no analgesic or psychological properties. Concomitant use of BZDs, opioids, and certain neuroleptic agents may relieve anxiety-provoking symptoms through a synergistic action.44,45 When used together, these drugs can be administered in lower doses less frequently, have fewer side effects, and can decrease or delay development of tolerance or dependence through the use of smaller doses of each drug. At lower doses, BZDs reduce anxiety without causing central nervous system sedation or a decrease in cognitive or motor function. With increasing dosages, inhibition of motor and cognitive functions as well as central nervous system depression does occur. Sufficiently high doses can induce hypnosis and coma.46

The most frequently used BZDs in critical care are midazolam and lorazepam. When midazolam is used as a continuous infusion, the dose can be 1 to 2 mg/h for mild sedation or as high as 25 mg/h for severe agitation if the patient is mechanically ventilated (see Table 43–1). If the degree of sedation is not adequate, the serum level of midazolam can be raised by one to three small bolus IV injections while simultaneously increasing the infusion rate.47

Lorazepam gives effective sedation and anxiety relief over a longer period than does midazolam. Cardiovascular and respiratory effects occur less frequently with this drug than with other BZDs. It may also act synergistically with haloperidol, a neuroleptic agent discussed later in this chapter. Lorazepam can be administered intravenously, intramuscularly, or orally. IV doses may be 1 to 10 mg every 6 to 8 hours. In the critical care setting, it can also be administered as an infusion at 1 to 5 mg/h and titrated to clinical effect.47

As with opioids, tolerance to BZD effects can develop in critically ill patients receiving midazolam infusions.39 In addition, BZD dependence can occur, evidenced by symptoms such as dysphoria, tremor, sweating, anxiety, agitation, muscle cramps, myoclonus, and seizures on abrupt medication withdrawal.39

It is important that patients in ICUs be routinely assessed for the presence of delirium.33 Haloperidol is a frequently used neuroleptic for critically ill patients with delirium. A loading dose of 2 mg can be administered, followed by twice that dose repeated every 15 to 20 minutes while agitation persists. Doses as high as 400 mg have been reported, but adverse effects may occur with these high doses.33 This drug has few cardiovascular effects unless given rapidly, in which case vasodilation and hypotension may occur. Haloperidol does not depress respiration; rather, it has a calming effect on agitated, disoriented patients, making them more manageable without causing excessive sedation. However, haloperidol has some significant adverse effects, such as reduction of the seizure threshold, precipitation of extrapyramidal reactions, and prolongation of the QT interval leading to torsades de pointes.39 Once a haloperidol drug dosage has been established, it should not be necessary to increase the dose to obtain the same effect over time, because tolerance should not occur.

Propofol is a highly lipophilic IV sedative/hypnotic agent that has a very rapid onset of action and short duration. It is indicated for use in the ICU to control agitation and the stress response in patients who are mechanically ventilated and those who require deep sedation for procedures.33 However, propofol has no analgesic properties and must always be used in conjunction with analgesics whenever the patient might experience pain. During initial use of propofol, a drop in systolic blood pressure, mean arterial blood pressure, and heart rate may occur in patients with fluid deficits and in those receiving opioids. The rapid loss of clinical effect of propofol renders it a valuable sedative agent in the critical care environment. Continuous infusion doses may range from 50 to 300 mg/h47 (see Table 43–1). The short effective half-life of propofol allows rapid clinical evaluation of the patient’s level of consciousness and determination of the minimum dose required for effective sedation. This may make it a useful drug during situations in which intermittent interaction with professionals and family members is desired.

### Nonpharmacological Interventions for Anxiety and Agitation

Numerous interventions exist that may promote tranquility and sedation in a critical care environment. These include control of environmental noise and the use of clocks, calendars, and personal articles such as pictures from home. Music therapy can be used to decrease anxiety and pain as well as promote sleep. As noted earlier, imagery and relaxation techniques also provide a means of distraction for patients and help to alleviate anxiety.37

The act of physically caring for a patient and providing gentle touch is a major source of comfort for patients in critical care. Taking the time to provide simple measures such as back rubs and massages, repositioning the patient, smoothing bed linen wrinkles, removing foreign objects from the bed, providing mouth and eye care, and taping tubes to maintain patency and inhibit pulling effectively promotes comfort and decreases anxiety. Family member participation in caregiving activities, such as bathing, massages, and back rubs, can have a powerful calming effect on patients and promote sleep and psychological integrity.

For alert patients, increasing opportunities for control is a strategy that can reduce the sense of helplessness that often
accompanied patients who are critically ill. This sense of control can be promoted by allowing alert patients to make decisions about the timing of interventions. Facilitating contact and communication with clergy, psychologists, or psychiatrists, if appropriate, can help to alleviate the distress experienced by both patients and families.

Other Distressing Symptoms

Scant research has been conducted on symptoms experienced by ICU patients at high risk of dying. A notable exception was the study by Nelson and colleagues.48 These investigators concentrated on the symptom experiences of ICU patients with current or past cancer diagnoses, because the expectation was that almost half of that group would die during hospitalization. Investigators used a modified Edmonton Symptom Assessment Scale (ESAS) to have patients rate their symptoms. The ESAS was modified by including or substituting symptoms they thought were more relevant to ICU patients and by using a four-point verbal descriptor scale (None, Mild, Moderate, Severe). In a sample of 100 patients who met inclusion criteria, 50% (mean age, 63 years; 64% male) were able to report their symptoms; 60% of these patients were mechanically ventilated. More than 50% of patients reported the following symptoms to be moderate to severe during “daily” assessments (exact number of days not reported): discomfort (75%), unsatisfied thirst (71%), difficulty sleeping (68%), anxiety (63%), pain (56%), and unsatisfied hunger (55%). More than one third of patients reported depression or shortness of breath or both. This study demonstrated that a high proportion of cancer patients at high risk of dying in ICUs experience substantial discomfort. Furthermore, half of the patients in the study were unable to report their symptoms, evidence of the ongoing challenge of symptom assessment in critically ill patients.

ICU nurses play a major role in alleviating distressing symptoms such as thirst, sleeplessness, and general discomfort experienced by patients at the end of life. Because nurses are the health care providers who are constantly at the bedside, they can assess the presence of these symptoms, advocate for effective pharmacological therapy, use additional nursing comfort measures, and provide for continuity of therapy. Symptom management is a special contribution that ICU nurses can make to their patients at the end of life.

End-of-Life Practice Issues: Withholding and Withdrawing Life-Sustaining Therapies

Limiting life-sustaining therapies in an ICU is becoming more common. It is estimated that withholding or withdrawing of life support precedes up to 75% of deaths in ICUs.49,50 Generally, life-sustaining treatment is withdrawn when death is believed to be inevitable despite aggressive interventions.

The President’s Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research51 supported the right of a competent patient to refuse life-sustaining and life-prolonging therapy. The Commission also noted that there is no moral difference between withholding and withdrawing therapy. A number of critical care–related professional organizations52–54 have published position papers in support of the patient’s autonomy regarding withholding and withdrawal decisions.

If patients are unable to make treatment decisions, these decisions must be made on the patient’s behalf by surrogates or by the health care team.55 Optimal patients’ living wills or advance directives can provide the direction for decisions related to treatment withholding or withdrawal. Yet, only 10% to 20% of patients complete them.55 When surrogates are asked to participate in decision-making, it is recommended that the decisions be made based on the following, in order of preference: (1) the patient’s previously stated wishes; (2) inferences based on the patient’s values or life goals; (3) the patient’s best interests, as determined by weighing the benefits and burdens of treatment.55 Families work with the health care team members caring for their loved ones to arrive at decisions to withdraw life support.54 They often struggle with concern that they are doing the right thing. Providing clear, consistent information about the patient’s prognosis (albeit in the face of prognostic uncertainty) provides support for families in their decision-making.

When a decision to forgo life-saving therapy is made in an acute care setting, there is a common sequence of withdrawal of therapies: blood products, hemodialysis, vasopressors, mechanical ventilation, total parenteral nutrition, antibiotics, IV fluids, and tube feedings.56 Withdrawal of therapies should be preceded by chart notations of DNR orders and a note documenting the rationale for comfort care and removal of life support.57 There should be a clear plan of action and provision of information and support to the family. Adequate documentation of patient assessments, withdrawal decisions and plans, therapy withdrawal orders, and patient and family responses during and after withdrawal is essential.58 There is considerable variability regarding physician documentation of discussions with families regarding withdrawal of life support.59 This lack of documentation may infer, rightly or wrongly, lack of interactions with families about treatment decisions.

Withdrawal of Ventilator Therapy with Consideration of Analgesic and Sedative Needs

It is important to understand the methods by which mechanical ventilation may be removed. The primary goal during this process should be to ensure that patients and family members are as comfortable as possible, both psychologically and physically. Two primary methods of mechanical ventilation removal exist: immediate extubation and terminal weaning.
Debates continue as to which of these methods is optimal for the patient, and often the method is determined according to the physician's, patient's, or family members' comfort levels.60 Although there is considerable variability regarding the preferred approach to withdrawal,61 recommendations regarding specific procedures for withdrawal are available.57–64 Table 43–3 presents a protocol for withdrawal of mechanical ventilation for the clinician's consideration that includes specific recommendations regarding use of analgesics and sedatives. Consensus guidelines on the provision of analgesia and sedation for dying ICU patients support the titration of analgesics and sedatives based on patient's requests or observable signs indicative of pain or distress.65 The guidelines emphasize that no maximum dose of opioids or sedatives exists, especially considering that many ICU patients receive high doses of these drugs over their ICU time course. “Anticipatory dosing” (Truog and associates,61 p. 2339), as opposed to reactive dosing, is recommended by some to avoid patient discomfort and distress.61,65

It is important to provide comfort to dying infants, who could experience pain and distress similar as older patients. Opioid analgesia was provided to 84% of 121 infants when life support was withdrawn or withheld in an intensive care nursery.66 Importantly, there was no difference in time to death according to opioid dose. As with older patients, attention must be paid to involvement of the family in decision-making, providing support to the family, and good documentation of decisions and treatments. However, documentation was found to be lacking for 18 infants who died after ventilator withdrawal.67 Without proper documentation, evaluation of competent and compassionate care is limited.

Research to guide the practice of ventilator withdrawal is scant. A small group of adult patients (N = 42) underwent withdrawal as part of a treatment limitation plan.68 Clinical data were collected from their medical records, including the specific method of ventilator withdrawal. Twenty-eight patients (85%) died after endotracheal tubes and mechanical support; 10 died with artificial airways in place but mechanical support removed; and 4 died after gradual removal of airway and/or mechanical support.

A Protocol for the Withdrawal of Mechanical Ventilation

I. Anticipate and prevent distress

A. Review process in advance with patient (if awake), nurse, and family. Identify family goals during withdrawal (e.g., ability to communicate versus sedation). Arrange a time that allows the family to be present, if they wish.

B. Provide for special needs (e.g., clergy, bereavement counselor). Assess respiratory pattern on current level of respiratory support.

C. Use opioids and/or benzodiazepines* to control respiratory distress (i.e., respiratory rate >24 breaths per minute, use of accessory muscles, nasal flaring, >20% increase in heart rate or blood pressure, grimacing, clutching). In patients already receiving these agents, dosing should be guided by the current dose.

D. In the absence of distress, reduce intermittent mandatory ventilation (IMV) rate to less than 10 and reassess sedation.

E. Discontinue therapies not directed toward patient comfort:
   1. Stop neuromuscular blockade after opioids and/or benzodiazepines have been started or increased.†
   2. Discontinue laboratory tests, radiographs, vital signs.
   3. Remove unnecessary tubes and restraints.
   4. Silence alarms and disconnect monitors.

II. Optimize existing function

A. Administer breathing treatment, if indicated.

B. Suction out the mouth and hypopharynx. Endotracheal suctioning before withdrawal may or may not be advisable depending on patient distress and family perception. Consider atropine (1–2.5 mg by inhalation q6h), scopolomine (0.3–0.65 mg IV q4–6h), or glycopyrrolate (1–2 mg by inhalation q2–4h) for excessive secretions.

C. Place the patient at least 30 degrees upright, if possible.

III. Withdraw assisted ventilation‡

A. In general, changes should be made in the following order§:
   1. Eliminate positive end-expiratory pressure (PEEP).
   2. Reduce the fractional oxygen content of inspired air (Fio2).
   3. Reduce or eliminate mandatory breaths.
   4. Reduce pressure support level.
   5. Place to flow-by or T-piece.
   6. Extubate to humidified air or oxygen.

B. Constant reevaluation for distress is mandatory. Treat distress with additional bolus doses of opioids and/or benzodiazepines equal to hourly drip rate and increase drip by 25–50%.

C. Observe for postwithdrawal distress, a medical emergency. A physician and nurse should be present during and immediately after extubation to assess the patient and to titrate medications. Morphine (5–10 mg IV q10 min) or fentanyl (100–250 µg IV q3–5 min) and/or midazolam (2–5 mg IV q7–10 min) or diazepam (5–10 mg IV q3–5 min) should be administered.

*Drug doses are difficult to specify because of the enormous variability in body weight and composition, previous exposure, and tolerance. In opioid-naïve patients, 2–20 mg morphine or 25–250 µg fentanyl, followed by an opioid infusion of one-half of the loading dose per hour, is a reasonable initial dose.

†Usually the effects of neuromuscular blocking agents (NMBAs) can be reversed within a short period, but it may take days to weeks if patients have been receiving NMBAs chronically for management of ventilatory failure. Neuromuscular blockade masks signs of discomfort. Therefore, clinicians should feel that the patient has regained sufficient motor activity to demonstrate discomfort.

‡There is no one sequence applicable to all patients because their clinical situations are so variable. The pace of changes depends on patient comfort and may proceed as quickly as 5–15 min or, in an awake patient to be extubated, over several hours.

§Patients who require high levels of ventilatory support may die after small adjustments such as reduction or elimination of PEEP or decrease in Fio2 to 21%. In such patients, the physician should be present during and immediately after the change in therapy to assess the patient.

mechanical support. Most of the patients (88%) received morphine during withdrawal. At some time during the withdrawal process, 64% of the patients exhibited at least one sign of distress, most often labored breathing or upper airway noise. The investigators reported that their data suggest that little is gained by gradual withdrawal of respiratory support.

Other investigators evaluated responses of 31 adult patients to rapid terminal weaning from mechanical ventilation.\textsuperscript{24} Using both observational and physiological measures, they determined that the predominantly comatose patients in their sample remained comfortable with the use of low doses of morphine and BZDs. A larger, randomized clinical trial of various methods of withdrawal may help to determine whether one method is more efficacious than another. Cumulative morphine doses from 1 to 70 mg/h have been reported to be used for terminal weaning.\textsuperscript{24,57,69–71} In a recent study of ventilator withdrawal procedures,\textsuperscript{57} bolus doses of opioids or BZDs or both effectively managed two thirds of 21 patients’ symptoms, whereas the remaining patients required continuous infusions. These research findings support the need for individualizing pharmacological support during life support withdrawal.

Patients should be withdrawn from NMBAs before withdrawal from life support. The use of NMBAs, such as vecuronium, makes it almost impossible to assess patient comfort; while appearing comfortable, patients may be experiencing pain, respiratory distress, or severe anxiety. The use of NMBAs prevents the struggling and gasping that may be associated with dying, but not the patient’s suffering.\textsuperscript{72} The horror of such a death can only be imagined. The withdrawal of these agents may take considerable time for patients who have been receiving them chronically, and patients continue to have effects from lingering active metabolites.\textsuperscript{81}

Regardless of the method used to withdraw life-sustaining therapies, the critical care nurse plays a major role during the decision and implementation of withdrawal of patients from mechanical ventilation. Increased nursing involvement can help provide optimal care to these patients. Specifically, the nurse can ensure that a rationale for, and all elements of, the plan have been adequately discussed among the team, patient, and family. The nurse can ensure that adequate time is given to families and their support persons, such as clergy, to reach as good a resolution as possible. The family needs reassurance that they and the patient will not be left alone and that the patient will be kept comfortable with the use of medications and other measures. As discussed earlier, opioids, alone or in combination with BZDs, are used during withdrawal to ensure that patients are provided the optimal degree of comfort.

The following case study, reported by a nurse, illustrates important aspects of withholding and withdrawing life-sustaining therapies.\textsuperscript{*}

Mr. G was an 84-year-old Caucasian man who had metastatic cancer. He was admitted to the hospital for aspiration pneumonia. He aspirated shortly after admission, developed respiratory distress, and was intubated and transferred to ICU. The next day, I saw the physician in the hall with the daughter and son, having what appeared to be a very emotional conversation. Shortly after that, the daughter walked into the room and stood by the edge of the bed. The physician came in, and the decision was made to withdraw support. The daughter understood her father’s condition: “He wouldn’t want this,” she said. I quickly arranged for a private area in the ICU room in which to transfer him. After getting the room ready, we moved them back there and I took over care. I tried to find out if there was anything special they wanted to do or needed before we took out the breathing tube. I was pretty sure it wouldn’t last long after that.

Morphine had given the patient nightmares in the past, so we started a drip of fentanyl and Versed. This helped to ease the daughter’s concerns about what her father was going to experience. After I was sure he had been adequately medicated, I removed the endotracheal tube. It was also very important to the daughter that any lines or tubes that could be removed had been. So the only thing I left was the IV tube to administer the medications. It was hard not to have that rhythm strip showing so that I could tell for sure when things were about to end. But I knew that is what the family wanted. Another nurse stopped in to see how we were doing and asked if they wanted their father shaved. She explained to me it would be nice for the daughter to be able to kiss his smooth face good-bye, especially if that was what she was used to. I was really struck by that idea; it hadn’t even crossed my mind. The daughter thought that would be nice, so I got the supplies. It turned out to be a beautiful experience. As I gently warmed his face and shaved him, his daughter told me that she was so glad that he had just been baptized into the Catholic faith and had received communion the previous week. It obviously meant a lot to her. Digging in her purse, she pulled out a Bible and read some scripture to him. She shared other things that she remembered about him, and we laughed together and then just quietly reflected.

His breathing had been a little labored as I began, so I increased his IV dosage. Right after I finished shaving his face the best that I could, the daughter looked at me. “Look at how his breathing relaxed and he calmed down when you did that. Thank you so much.” To her, the touch and caring had made the difference.

Finally, his breathing stopped, and I nodded that it was over.

\textsuperscript{*}The authors thank Julie Waters, RN, for providing the case study. Modifications to Ms. Waters’ original case study have been made by the authors.
Care for the Family of the Dying ICU Patient

Although the focus of care in many critical care areas is on the critically ill patient, nurses and other clinicians with family care skills realize that comprehensive patient care includes care of the patient’s family. A reciprocal and all-important relationship exists between the family and the critically ill family member. A change in one affects the other, and vice versa. Classic and contemporary research that describes the anticipatory and acute grief reactions experienced by family members when their loved one is dying point to this powerful reciprocal relationship. Therefore, no discussion of palliative care in the ICU is complete without also discussing care of the dying patient’s family. Family is defined here as any significant other who participates in the care and well-being of the patient.

The clinical course of any given critically ill, dying patient can vary tremendously, ranging from a rapid unfolding over several hours to a gradual unfolding over several days, weeks, and even months. How a family copes, of course, is also highly variable. Caring for families at any point along the dying trajectory, however, encompasses three major aspects: access, information and support, and involvement in caregiving activities.

Access

A crucial aspect of family care is ensuring that the family can be with their critically ill loved one. Historically, critical care settings have severely restricted family access and discouraged lengthy family visitation. Commonly cited rationales to limit family access include concerns regarding space limitations, patient stability, infection, rest, and privacy; the negative effect of visitation on the family; and clinicians’ performance abilities. Some of these concerns have merit, whereas others, such as adverse patient-related issues and a negative effect on the family, have not been borne out in the research literature.

Many ICUs around the world routinely limit visitors to two at any one time. Space limitations in critical care areas can be profound, because most ICUs were designed for efficient use of life-saving machinery and staff and were not intended for end-of-life vigils by large, extended families. Ensuring that all interested family members have access to their loved one’s bedside can present challenges to the already narrow confines of the ICU. However, family members of dying loved ones should be allowed more liberal access (both in visiting time and in number of visitors allowed). Patients are confronting what may be the most difficult of life passages and they, therefore, may need support from their family members.

There is a growing body of literature that supports family access to patients during invasive procedures and resuscitation. Facilitating family access during such times has come to be known as facilitating family presence, a practice supported by the Emergency Nurses Association and the American Heart Association. Researchers have investigated the impact of family presence on patients and found increased patient comfort and satisfaction. Studies examining family satisfaction with family presence have yielded similar results, and one study found no adverse psychological effects on the part of family members after the witnessed resuscitation.

Because children as young as 5 years old have been reported to have an accurate concept of death, their visitation needs should also be considered when a family member is dying. Although researchers investigating family presence in pediatric populations have found increased behavioral distress in children when parents were present, both parents and children overwhelmingly prefer family presence. With proper preparation and debriefing, children can visit a critically ill family member in the ICU without ill effects.

Finally, caring for the critically ill, dying patient and her or his family can call forth feelings of failure for clinicians bent on cure and force health care providers to reflect on their own mortality. Perhaps this helps to explain why so many health care providers believe that family presence is stressful and disruptive to the health care team caring for the critically ill patient. Yet, one study found that family presence did not affect self-reported stress symptoms in health care providers participating in the resuscitation events. The emotional burden for health care providers when providing palliative care is discussed later in this chapter.

Information and Support

Information has been identified as a crucial component in family coping and satisfaction in critical care settings. Support, in the form of nurses’ caring behaviors and interactions, is enormously influential in shaping the critical care experience for both patients and their families. In the context of caring for a critically ill, dying patient, however, nurses and physicians alike have reported high stress related to “death-telling,” or notifying family members of the patient’s death or terminal prognosis. These same studies point to the fact that few health care providers feel they have the skills and knowledge necessary to counsel families effectively during this emotionally charged time. The ethical principle of honesty and truth-telling collides with the limits of knowing the truth precisely when there is clinical ambiguity and also with the suffering imposed on a family having to face the hard truth. Compassionate truth-telling requires dialogue and relationship, timing, and attunement, all of which are relational aspects that are frequently overlooked in the hectic pace of the ICU. Add patient, family, and health care provider culture to the equation, and one can readily understand why communication between involved parties is a less than perfect science. The educational implications for clinicians are addressed later in this chapter.

Overall satisfaction with end-of-life care has been shown to be significantly associated with completeness of information received by the family member, support and care shown to the patient and family, and satisfaction with the amount or level of health care received. Family conferences have been used extensively as a means to improve communication between health care providers and family members, yet few studies have investigated best practices in relation to the timing, content,
and participants necessary for optimal communication during a family conference.\textsuperscript{110–112}

Some hospitals have created interdisciplinary teams of helping professionals to work with hopelessly ill patients and their families, in an effort to meet patients’ and families’ physical, informational, and psychosocial needs.\textsuperscript{113–117} Such teams usually include a nurse, physician, chaplain, and social worker. Working in concert with the nurses and physicians at the bedside, these interdisciplinary teams can more fully concentrate on end-of-life issues so that, theoretically, no patient or family needs go unmet during this time.

Finally, because feelings of grief in surviving family members are still commonly unresolved at 1 year after a loved one’s death, many critical care units across the lifespan have organized bereavement follow-up programs.\textsuperscript{118–122} These programs typically involve contacting the surviving family (by telephone or by mail) monthly for some period of time and at the 1-year anniversary of their loved one’s death. In addition to remembering and supporting the family, these programs have also been shown to help health care providers cope with the loss as well.

Involvement in Caregiving Activities

Few interventional studies have examined the effect of family involvement on critically ill patients and their families, yet families should have the opportunity to be helpful.\textsuperscript{61} Two studies investigating expert nursing behaviors in caring for the dying patient’s family found that expert nurses encouraged family participation in patient care.\textsuperscript{118,119} Family involvement in caregiving can range from minor activities (such as assisting with oral care or rubbing the dying patient’s feet) to major activities (assisting with postmortem care). This involvement may be helpful for family members in working through their grief by demonstrating their love in caring and comforting ways. Being involved in meaningful caregiving activities can make a family member feel useful rather than useless and helpful rather than helpless.

Although physical death occurs in the dying patient, the social death is felt in the patient’s surviving family. Because the perception of death lingers at the family level long after the physical death has occurred, involving family members who are interested in participating in their loved one’s care may go far to provide closure, comfort, and connection. Unfortunately, many critical care nurses still feel that families should provide a supportive but nonparticipative role in their loved one’s provision of care.\textsuperscript{120,121} Nurses’ facilitation of family involvement in their dying loved one’s care is a practical family intervention which should be more widely employed if humane and comprehensive palliative care is desired.

Sharing Narratives

Debriefing, either formally or informally, has been used effectively in many settings to discuss and process critical incidents; analyze health care providers’ performance in terms of skill, knowledge, and efficiency; and learn, both personally and institutionally, from mistakes and system breakdown.\textsuperscript{92,124–126} Sharing stories or narratives of practice can be used to achieve the same goals, but in addition telling stories from practice enables clinicians to (1) increase their skill in recognizing patient and family concerns; (2) learn to communicate more effectively with patients, families, and other health care providers; (3) reflect on ethical comportment and engaged clinical reasoning; and (4) articulate clinical knowledge development.\textsuperscript{123,127}

Creating the interpersonal and institutional space in which to both tell and actively listen to stories from practice also enables health care providers to share skills of involvement and sustaining strategies. These understandings can provide clinicians with guidance—and in some cases, corrective action—to intervene in ways that are true to the patient’s condition and to the patient’s and family’s best interests.\textsuperscript{105} Through reflection and dialogue with others, nurses and other health care providers can pool their collective wisdom and extend their care of dying patients and their families.

Death Education

Closely coupled with sharing clinical narratives is the use of seminars and other reflective exercises aimed at preparing nurses and other health care providers for the care of dying patients and their families. Death education often consists of didactic and experiential classes. Participants in these classes are encouraged to reflect on and share their own perceptions and anxieties about death, as well as their attitudes toward care of the dying patient and his or her family. This approach has been used with varying degrees of success with nurses, nursing students, and physicians.\textsuperscript{128–130} Because many health care providers feel uneasy and ill-prepared to effectively care for
In this clinical incident, a critical care nurse described a 70-year-old patient who was admitted to the ICU with end-stage liver failure. The patient's son was an ICU nurse himself and was the patient's primary caregiver at home. The nurse described her relationship with the patient's son developed:

**Nurse:** [The patient] had diabetes, hepatitis C of unknown etiology, and end-stage liver failure. And the [patient's] son would go to the library and pull up articles on hepatitis C and hepatorenal syndrome. You know, he wanted her started on CVVH (continuous veno-venous hemofiltration) because somebody else was on it and because [the therapy] was a kind of hope. The son was with [the patient] when she was on the ward too, and he pretty much called the shots, or that's the impression I got from the floor nurses. And I guess some nurses in the ICU might have felt that way about him too, but this was his mom, and I guess I can understand his wanting to be involved. That's the only mother he has. Anyway, I guess I don't feel threatened by family members who need to be involved. . . . Over the next 3 weeks, I [involved the son in her care]—he was like my extra pair of hands. I mean, he takes care of her at home and he's a nurse. So, why ignore that part of him—that is him. He takes care of her, she wants him there, she was calmer when he was there, and he wants to help. He helped me turn her, he gave her back rubs, he was just there. And I passed that on from shift to shift. I said, "He wants to help. Let him. Why go look for somebody else when somebody who wants to help is right here?" Being involved gave him a sense of helping and doing something [for his mother]. If everything works out, he'll be caring for her at home. He needs to know what her skin looks like. . . . Another thing about that family, I always take it as a compliment when a family feels they can leave when I'm taking care of their family member.

**Interviewer:** And why is that?

**Nurse:** Because I think that means that they trust me and that it's OK for them to leave. Even after nights and nights of staying with his mother, [the son] was still able to go out and take a break for himself. He knew I would call him on his cellular phone if anything came up. . . . But it was a pretty hopeless situation. She was evaluated for a liver transplant but was not a candidate because of her age and her diabetes. . . . It just got to a point where it looked like [the patient] was suffering so much. She just got more and more bloated, she was like twice the size she normally was. So, we ended up withdrawing support late in the shift. They were short the next shift, so I stayed over with the patient and family for another 4 hours just to kind of finish up with them. I didn't want them to have yet a new face [work with them] for the last hour or two of her life. Nobody who had been following this patient was back on nights, and there were no other co-primaries coming on. And it wasn't that big of a deal, but I guess it was for them. About a week and a half later, the [patient's family] came in and brought me this humongous cake and two dozen roses! So, it was really a good experience, because, even though it was a sad outcome, they felt supported and that was pretty much the only goal I had for them.

This clinical incident illustrates the three major aspects of caring for families of dying patients: access, information and support, and involvement in caregiving activities. The nurse in this situation tailored her family care to match what was both required and desired by the patient's son. Because the son was a nurse himself, he researched his mother's condition extensively and suggested different treatment modalities. Rather than being threatened by the son's interest, the nurse understood and supported him. The nurse ensured that the son had liberal access to his critically ill mother and encouraged hands-on involvement in his mother's care.

The nurse developed a trusting relationship with the son, which enabled him to leave his mother's bedside with confidence, knowing that he would be called with any changes in her status. This trusting relationship also helped, no doubt, when discussions concerning his mother's prognosis arose. Because the son trusted the nurse, one can imagine, for example, that he actively listened to her when the nurse pointed out his mother's bloated condition while they were bathing her together. These daily and often mundane encounters helped to forge the nurse-son relationship, from which both drew great satisfaction.

Once the decision was made to withdraw life support, the nurse stayed past her shift to continue her work with the grieving son. The nurse "stayed over" out of respect for the relationship that had developed, but also to provide the son with a "familiar face" during the uncharted and emotionally charged passage of his mother's life. Because this nurse was bearing witness to the death in particular ways shaped by the nurse-family relationship, a new person would not be able to enter the situation and support the son in the same way. The nurse responded to the ethical responsibility of being in a relationship with the patient's family and, in so doing, facilitated the son's closure with this major family event.

**An International Agenda to Improve Care of Dying ICU Patients**

Considerable emphasis is now being placed on improving care at the end of life for ICU patients. The first book that comprehensively and specifically addresses ICU end-of-life care has.
been published. The Society of Critical Care Medicine’s 30th Critical Care Congress in 2001 devoted an entire educational track to this topic. A Working Group of experts in critical care and other relevant specialties, whose work was funded in part by the Robert Wood Johnson Foundation, developed a research agenda for end-of-life care in ICUs. A Robert Wood Johnson–sponsored national ICU Peer Workgroup on end-of-life care is conducting several education and research initiatives related to this topic. One of these initiatives is the development of quality indicators for end-of-life care in ICUs. These quality indicators can provide a framework for interventions to improve care of the dying in ICUs. An international consensus conference was held in 2003 to gather the evidence to date on end-of-life care in ICUs and make recommendations for practice and research. Recently published recommendations from this conference provide directions for practice improvements. Currently, the Robert Wood Johnson Foundation is funding demonstration projects in four ICUs in the United States. These demonstration projects are developing palliative care models for ICUs and assessing the impact on the quality of care for patients and their families. It is anticipated that findings from these demonstration projects will guide national and international practice improvements.

Summary

As noted by Todres and colleagues, “There is not one best way to die.” However, the authors believe that provision of a pain-free, ethically intact, and dignified death is the right of all ICU patients. Research to date has offered little guidance for managing the issues that surround ICU patient deaths. However, Chapple presented important goals to consider during an ICU patient’s dying process: (1) honor the patient’s life, (2) ensure that the patient and the family are not abandoned, (3) provide a sense of moral stability, and (4) ensure the patient’s safety and comfort. ICU nurses can feel privileged to strive toward the accomplishment of those goals.

The Outpatient Setting

I am so glad that you are there for me...someone on the other end of the phone who knows what to do when I just can't sort it out.—Annette, 56, colon cancer patient

Key Points

- Twenty-four-hour accessibility to health care providers is critical to providing palliative care to outpatients.
- Evaluation and management of physical, emotional, and spiritual distress at each office visit are primary components of outpatient palliative care.
- Active listening in the office and at telephone triage contributes greatly to individualizing the plan of care.
- Providing a sense of control for patients and their families is an integral part of palliative care.

Dramatic changes over the last two decades have resulted in shorter and shorter hospital stays, longer survival with chronic debilitating disease, and smaller, fractured families—all of which have contributed greatly to increased use of outpatient services. Outpatient care is delivered in private practice offices, free-standing clinics, and hospital-based outpatient settings. Individuals with chronic and terminal illnesses receive care over time in the outpatient clinic or office setting. In these settings, significant long-term relationships develop among providers, patients, and families. As patients move toward the end of life, visits to the clinic provide an excellent opportunity to assess the patient’s and family’s needs, desires, struggles, and fears.

The months or years spent providing and receiving care in an outpatient setting are fundamental to establishing trust between the care team and the patient. This trusting relationship is vital both early in the disease continuum and at the end of life. Building this relationship is a critical component of the palliative nursing role.1,2 Unlike in an acute care setting, patients and families have time scheduled with physicians and staff to address their needs. This allows families to avoid the frustration of waiting in a hospital room trying to connect with a physician or nurse to raise issues or ask questions. The patient’s and family’s questions are answered and processed at one visit, and further clarifying questions and detailed responses can ensue at the next office visit.

In most cases, an outpatient setting is more intimate and less crisis driven than a hospital setting. On the other hand, patients may have excessive time in the waiting room and may be in very different stages of disease than others surrounding them. In the best situation, patients and families meet and support each other and facilities use waiting room space to make educational materials readily available.

There is generally a certain structure to the clinic visit that can lend itself to the integration of palliative care. In addition to taking a history, performing a physical examination, and reviewing medication history, the clinician can effectively
integrate a discussion about advance directives into the routine. Treatment plans can be discussed and negotiated with the patient. An assessment of pain and symptoms can be done at the time vital signs are taken or during telephone triage. The pain-related standards for outpatient care of the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) can be used to help incorporate pain and symptom management into the routine documentation of outpatient care.

**Challenges in Outpatient Care**

A number of challenges associated with the outpatient setting exist. The absence of a strong nursing presence is arguably the most critical barrier to the successful integration of palliative care. For example, ideally, in an outpatient oncology practice, registered nurses would be on staff to administer chemotherapy, to provide patient teaching, and to staff telephone triage systems. Assistant personnel are used for non-nursing duties, such as cleaning equipment, stocking, setting up examination rooms, and scheduling. However, with shrinking resources available in all spheres of health care, the use of nonlicensed personnel is expanding, and this trend is not likely to be reversed.

Although it is generally considered preferable for licensed personnel to be responsible for duties such as medication administration and telephone triage, many outpatient settings employ medical assistants or administrative assistants to collect intake data, take vital signs, and answer telephone calls. In many cases, nurses are being asked to do a greater number and variety of treatments, leading to a feeling that there is not enough quality time with individual patients. Some offices have no registered nurse at all in the outpatient setting, causing patients to have to wait for a chance to speak with the doctor before any assistance or suggestions can be offered. This can result in considerable delay in addressing symptom management issues and is clearly less than optimal.

Managed care has played a role in further splintering outpatient care in some medical centers. For example, with a reduction in reimbursement for chemotherapy, patients may be required to receive their treatment at an infusion center, along with patients receiving antibiotic therapy, inhalation therapy, and other treatments, far from the cancer center. Although this is a more cost-efficient way to provide parenteral therapy, it offers less continuity of care over time than does having outpatient cancer center nurses provide all care, from diagnosis through active treatment and on to palliative care.

Although registered nurses in office settings increasingly are being replaced by nonlicensed personnel, the increase in the use of nurse practitioners as physician extenders in outpatient care is a positive development. These advanced practice nurses can enable same-day office visits for emergencies or symptoms that require acute management. Many clinics use nurse practitioners to take histories and perform physical examinations for routine admissions to the hospital, while the physician sees patients in the clinic. A new and growing specialty group of acute care nurse practitioners sees very ill or unstable patients in the hospital, again working closely with the physician to balance outpatient and inpatient services. Advanced practice nurses have a higher comfort level with discussing end-of-life issues and maintain a high level of expertise in pain and symptom management (Figure 44–1). Another area where advanced practice nurses greatly affect care is that of transitions in the goals of care. Clinics have heterogeneous populations of patients, whose status may range from the early stages of diagnostic workup all the way through end-of-life care. Taking a lead role in helping to continuously reevaluate the goals of care with patients and families is a key impact area of advanced practice nurses.

One challenge facing advanced practice nurses in some states is the lack of prescriptive authority. In some states, advanced practice nurses, trained and skilled in palliative care management, are allowed to assess pain, address symptoms, and develop treatment plans but may not prescribe controlled medications. This limits patients’ access to pain and symptom management and creates a cumbersome process for refilling pain medications and addressing needs for anxiolytic agents. These practitioners often become experts at the optimal use of nonsteroidal antiinflammatory drugs (NSAIDs), co-analgesic agents (e.g., tricyclic antidepressants, anticonvulsants), antiemetics, bowel care agents, and a host of other pharmacological therapies. Several states do allow nurse practitioners full prescriptive authority, which improves access to palliative care. They are able to see patients with pain or symptom problems on the same day and prescribe therapy without the presence of a physician. Patients do not have to wait to receive a written prescription from a physician or travel to an emergency room to be seen by physicians not familiar with their cases.

Finally, another significant challenge in the outpatient setting is managing the increasingly burdensome gatekeeper role. Before a chronically ill patient can be discharged from an acute care setting, arrangements for extended care or home nursing must be made by a hospital discharge planning team. Once this plan of care is established, the outpatient team must coordinate and facilitate the patient’s care plan. This can be an overwhelming burden on outpatient nurses, who must constantly field telephone calls and faxes, fill out disability or family leave paperwork, and communicate with caregivers in the community. Balancing the telephone calls that urgently need attention with those of a more bureaucratic nature is a significant problem in many practices. Keeping track of what is happening with outpatients is difficult in the best-staffed clinics and may be overlooked entirely in poorly staffed settings. Return visits to the clinic are vital for evaluating treatment outcomes, assessing ongoing needs of patients, and effectively managing available resources. If clients are unable to travel to the clinic, provider visits to a nursing home, or timely referral to home health care with a focus on continuity of the treatment plan is very important. Incorporating all aspects of the team across inpatient, outpatient, and home care facilitates the best in palliative care outcomes.
Pain and Symptom Management
Waiting Room Checklist

Patient Name: ______________________
Date: ______________

Since you saw your doctor last have you had any “new” pain or symptoms?

Yes  No

The level of pain is described on a 0 to 10 scale where 0 is no pain and 10 is the worst pain you can imagine. Please circle the number that best indicates the level of pain you have had over the last 24 hours:

Are you having any problems with your medications?

Yes  No

Is there anything that you feel is a priority to discuss at today’s clinic appointment? (if yes, please indicate what)

________________________________________________________________________

Figure 44-1. Patient waiting room checklist for pain and symptom assessment. The questions relate to pain and any side effects of analgesics—information that can facilitate discussions of symptom management.
The two major benefits of the outpatient setting are a more intimate, structured environment and more time to develop long-term relationships. However, the setting also has disadvantages: fewer registered nurses, the increased burden of gatekeeping, and poor access in busy outpatient practices. Providing quality palliative care in the outpatient setting requires creativity and commitment to meeting these challenges.

Integrating Palliative Care into Outpatient Care

A combination of philosophical mission, strategic planning, and bottom-line pragmatism is necessary to integrate palliative care successfully into the current outpatient medical model (Figure 44–2). The philosophical mission must come from the institution and the strategic planning from administration, but the practical, day-to-day implementation occurs in the clinical practice at the hands of nurses and physicians. Integration of palliative care must begin at the initial visit and continue through the ongoing evaluation and management process.

Assessment

Assessment of the patient’s and family’s goals and preferences begins during the initial meeting. In most outpatient settings, a baseline history, a physical examination, radiographic studies, and laboratory tests should accompany a review of preventive, general, or specialty health care needs during the first few office visits. A routine evaluation of current health needs and preventive health issues can be followed by a review of end-of-life care preferences. If such a discussion is delayed and occurs during a later or exacerbated illness, the patient and family are much more likely to fear that death is imminent or that the doctor is “holding something back.” This makes it much more difficult for all involved to reach clarity concerning the patient’s goals. A sample clinic conversation is shown in Table 44–1.

If the patient already has a life-threatening diagnosis, it is appropriate early on to establish a routine for assessing pain, fatigue, nausea, and other physical, psychological, and functional parameters. It is critically important to establish a standard approach to assessing the palliative care needs of the patient and family in the outpatient setting. To save time and obtain preliminary information, patients may be given a standard form to fill out before the examination. This can also help narrow down the priority issues for the visit. Increasingly, electronic forms are being used; they may be accessed through a waiting room kiosk or even over the Internet from the patient’s home.

Patients and their families should be educated early about the importance of symptom assessment and reporting as well as evaluation of treatment efficacy and side effects. Establishing the patient and family as part of the team improves outcomes. As always, the patient’s goals of care become the central focus for facilitating optimized palliative care. A sample dialogue is shown in Table 44–2.

Reassessment of pain and symptoms should occur with new or continuing problems and with a reasonable frequency and method. For example, if a patient with pain level of 7 on a scale of 10 is seen in the office for opioid titration, an explicit follow-up assessment plan should be established before the patient leaves the clinic. Either a clinic nurse should telephone the patient in a day or two, or alternatively, the patient or a family member should call the office nurse if the pain level does not drop below 4 within a day or two. Patient instructions should be specific, such as, “Call the clinic if you go 3 days or longer without having a bowel movement,” or “Call the clinic tomorrow if the antinausea medicine is not working.”

---

**Table 44–1**

**Sample Dialogue for Opening Advanced Directive Discussion**

**Nurse:** Mrs. Jones, have you thought about what you want us to do if your heart stops?

**Mrs. Jones:** Oh goodness, no. I’m healthy as can be.

**Nurse:** Do you have a living will?

**Mrs. Jones:** No. I don’t like to think about that sort of thing.

**Nurse:** It’s true that most healthy people don’t want to talk about dying, but we need to discuss all aspects of your health care, including end-of-life care, so that we’ll be able to do the best job possible of treating you and at the same time respecting your wishes.
instructions may be incorporated into a standard handout for patients and then individualized as needed (Table 44-3).

Because some patients and family members are hesitant to “bother” the clinic with telephone calls, it is often desirable for the reassessment telephone call to be initiated by the clinic. These reassessment, or “check-back,” calls can be done by a trained medical assistant or other nonlicensed personnel (Table 44-4). Although the use of nonlicensed personnel is controversial, it is increasingly accepted as part of the priorities for containing spiraling costs. Training in the triage of critical symptom problems is the key to optimal use of nonlicensed staff.

An organized reminder system for callbacks should be instituted. One method is to route a copy of the patient’s last waiting room checklist (see Figure 44-1) or “Things to Report to the Clinic” sheet to a medical assistant or clerk for follow-up. As with telephone triage, the caller must be given clear criteria for what to do with the information obtained (e.g., document resolved problems, report unresolved problems to the provider). Criteria for further follow-up can be established so that unresolved symptoms identified by the office nurse or medical assistant at telephone triage lead to notification of the physician and further revision of the treatment plan. For example, any new problems should be triaged by a registered nurse or physician. Telephone triage notes can be designed for easy completion, using “check-off boxes” and “circle the symptom” documentation styles (Figure 44-3).

Patients who have a knowledge deficit about their medications or treatment regimen require one or more follow-up calls from a registered nurse or pharmacist. It is extremely helpful to provide the patient with written descriptions of medication changes or significant changes in the plan of care.

Some larger institutions have separate palliative care physicians or nurses who work alongside the primary treatment team and often are called in if a certain symptom (e.g., such as pain consistently >6/10) or a high-risk diagnosis (e.g., amyotrophic lateral sclerosis) is present. These specialty teams work most effectively alongside the primary providers when clear screening guidelines for engaging the service are in place. This is another area in which the advanced practice nurse often plays a role (i.e., early identification and referral for palliative care services).

New or escalating symptoms require timely response by the outpatient team. A reasonable time frame should be set for follow-up of new problems. Ideally, the patient should be seen within 12 hours after the onset of new symptoms—essentially the same day, if possible. This is particularly true for patients with significant symptom management issues, for whom trips to the emergency room or urgent care center would be extremely tiring and would result in the patient’s being evaluated without all pertinent data available. Any patient with significant new or escalating symptoms who is seen in an emergency room should be seen again in the outpatient setting within 24 to 48 hours. If the patient receives home care or is involved with a hospice, an initial evaluation can be done at home, with telephone contact with the clinic. If home care or hospice care is not in place, an escalation of symptom management problems often is a very good indication that these resources should be initiated immediately.
At its core, the outpatient setting is concerned with evaluation and management (E&M). The E&M codes drive reimbursement and consequently dictate documentation requirements. The "evaluate and treat" construct is deeply entrenched in the traditional medical model. However, neither the reimbursement-driven E&M process nor the traditional medical model always supports palliative care. In fact, one of the most persistent problems in palliative care is the "hospice as last resort" assumption of some providers, which causes referrals from the outpatient setting to a home care agency within the last days of life and virtually never before suspension of active treatment. This late utilization of home health resources is further complicated by the "crackdown" on Medicare fraud in home health care and has resulted in drastically reduced home care stays across the country.

Some providers also worry that hospice care will "take over" and that the patient will not have access to appropriate medical oversight. In such cases, the provider essentially "loses" a patient and family with whom he or she has developed a relationship during long-term treatment. In some cases, this concern results in an "us or them" mentality in which everyone loses. Most providers, even if a hospice physician takes over the primary responsibility for managing the patient's care, do stay involved, if only through periodic telephone follow-up.

Many clinicians reject the stark line drawn between active treatment and palliative care and successfully merge these concepts in outpatient care. Conceptually, this model was described by the World Health Organization. The "old" model depicts health care system involvement starting from diagnosis with active treatment and then abruptly, shortly before death, switching to a purely palliative model. The "new" model depicts the health care system using active and palliative care concurrently, with a primarily active treatment focus at diagnosis, integration along the trajectory, and a primarily palliative focus at death (see Fig. 44–2).

Take, as an example, an elderly gentleman with metastatic prostate cancer who has begun hospice care and has developed pain, rated as 9 on a scale of 0 to 10, that begins in his back and

Figure 44-3. Example of a telephone triage tool—a concise assessment and treatment progress note designed for telephone interview for triage of pain and symptoms.
Figure 44-4. The Du Pen Cancer Pain Algorithm—an algorithm designed to aid decision-making in outpatient management of cancer pain. Use of this algorithm in clinical trials produced a significant ($P < 0.02$) reduction from usual pain levels. (Source: Adapted from Du Pen S, Du Pen A. Cancer Pain Algorithm Reference Guide. Seattle: Du Pen, Inc., 1998:6–10. © 1998)
shoots down his legs. His opioid therapy has been increased aggressively over the past week, and he is now somnolent between periods of extreme pain. His wife also notices he needs more help getting out of bed because his legs “won’t hold him up.” The patient and his wife explain that their goals are to keep his pain under control and to keep him as functional as possible. This patient may benefit dramatically from steroids and radiation to reduce pain and save the functions of his lower extremities, bowel, and bladder, even though he is receiving hospice care. In such situations, a very clear understanding of the patient’s and family’s goals of care, well defined and known to both outpatient providers and home care or hospice care providers, facilitates the best possible outcomes.

Treatment algorithms or protocols can promote efficiency in the clinic and enhance outcomes. These tools can be successfully put into place and implemented by both clinic nurses and home care or hospice care nurses. One such algorithm was used in outpatient oncology and resulted in improved pain management. The Cancer Pain Algorithm is a decision tree model for pain treatment that was developed as a practical interpretation of the Agency for Health Care Policy and Research Guidelines for Cancer Pain Management. The algorithm consists of a bulleted set of analgesic “guiding principles” for use with opioids, NSAIDs, tricyclic antidepressants, anticonvulsants and addresses drug side effects. For example, the statement “Titrate to efficacy or side effects” is an underlying principle throughout the algorithm. Drug choice decisions depend on pain assessment data. The flow chart directs the oncology nurse or oncologist to side effect protocols, equianalgesic conversion charts, and a primer for intractable pain.

Figure 44–4 represents the high level algorithm decision-making flow chart. Etiology and location correlate the pain with its known tumor or treatment-related source or indicate the need for further diagnostic work-up. Pain intensity is based on self-report on a scale from 0 to 10, where 0 is no pain and 10 is the worst pain imaginable. Pain character is divided into nociceptive versus neuropathic components; the character of the pain is the primary variable to direct the choice of nonopioid or coanalgesic therapies. The frequency and method of reassessment are outlined for the practitioner based on the results of the last pain assessment contact. An algorithm reference tool contains drug-specific content (e.g., titration parameters, side effect protocols) and a number of highly specific flow charts. The algorithm process is intended as a team effort, relying on the network of physician, clinic nurse, home care nurse, and family caregiver as a cohesive outpatient unit, all applying the principles of the algorithm as they relate to the individual patient.

Another concept now being used in outpatient care is that of the primary nurse “navigator.” The navigator takes the concept of case manager a step further, in the sense of acting as a “learned guide” rather than a plan “manager.” The navigator is responsible for tracking the course of the patient’s care through the myriad of services. A treatment plan becomes a “road atlas,” and the nurse navigator steers the patient’s care to the key stops along the highway. These stops may be follow-up diagnostic studies, interdisciplinary consultations, hospice referrals, or a variety of other patient-specific services. This model works well for outpatient services that, in general, are disconnected one from another and that might be overlooked under strained resources. The navigator works from critical pathways, or algorithms, and provides feedback to the physician weekly.

Critical Building Blocks for Outpatient Palliative Care

A number of critical elements provide an excellent framework for integrating basic palliative care concepts into almost any outpatient setting. Improving provider accessibility to patients and caregivers, promoting active listening by all staff, providing a sense of control, and continuously assessing psychological and spiritual distress of patients and their families are the building blocks to successful outpatient palliative care.

Accessibility

In the outpatient setting, accessibility is critical to the palliative care of patients. Having 24-hour support available to patients and their caregivers helps reduce anxiety and, when necessary, facilitates identification of after-hours problems that need immediate attention, such as escalating pain or shortness of breath. Accessibility is not, of course, only an after-hours issue. A well-organized telephone triage system is necessary to provide access during regular clinic hours. The clerk or other nonlicensed personnel who answer the telephone should receive very clear instructions on how to distinguish problems that need immediate attention. For example, billing questions and insurance issues receive callbacks, whereas pain, shortness of breath, and changes in level of consciousness require a nurse or physician to take the call. These criteria should be agreed upon by all and followed consistently. Calls that require high-level triage should be handled by trained nurses armed with protocols and standing orders that have been approved by the patient’s physician. The triage system should include procedures for bringing patients into the clinic for same-day evaluation or for admission to the hospital. Such a system has three main benefits: (1) the patient sees the nurse as a qualified member of the team who is available and ready to assist; (2) the patient and family caregivers become more confident in making adjustments to medications for pain or symptom management, and (3) telephoning allows the nurse to reassess, reassure, and reinforce the teaching that has taken place (see Figure 44–3).

Advanced practice nurses clearly improve accessibility for patients undergoing palliative care management. Many nurse practitioners share on-call responsibilities with physicians, thereby alleviating some of the workload that 24-hour
accessibility requires. Flexible scheduling of advanced practice nurses can allow for “same-day work-ins,” nursing home visits, or home visits, as circumstances require.

Active Listening

Active listening is a key element to effective communication among patients, the outpatient care team, and the patients’ families. This component of palliative care helps to support patients and families who feel physically and emotionally isolated or overwhelmed by a terminal illness. Active listening also leads to more efficient use of time and a stronger relationship with the client, which are important factors in the outpatient setting, both during face-to-face interactions and over the telephone. The astute listener simultaneously watches for nonverbal clues, shows empathy, and assesses the patient’s and family’s knowledge base. In the outpatient setting, staff become more familiar with the patient and family over months and perhaps years, which makes the process of listening actively and with empathy easier. This ability and opportunity to make assessments over a long period is unique to the outpatient setting.

Oncology nurses are sometimes comfortable opening a dialogue with patients about pain, fatigue, weight loss, and appetite but less comfortable handling conversations about death and dying or loss. If a formerly hopeful patient with a “fighter” attitude responds with “I don’t think I can do this anymore,” the active listener understands that a transition is occurring. Time must be set aside for this patient, either immediately or with a plan for a follow-up telephone call or family conference. Time spent proactively facilitating these transitions almost always saves crisis-induced time spent later in the patient’s course.

Another critical component of active listening involves identifying barriers to effective palliative care. The classic example of a barrier to care is the fear of opioid addiction. A clinic nurse often first identifies the patient’s or family member’s concern about taking opioids. It is important to discuss this attitudinal barrier early and frequently. Another barrier to pain management at the end of life is the belief that using pain medications hastens death. Because of this belief, family members may resist optimizing opioids and adjuvants at the end of life. In addition to verbal instructions at the time of the clinic visits, written materials on the rationale and role of symptom management in end-of-life care can be extremely helpful.

Another issue that is frequently present and often requires active facilitation by clinic staff is the social context of care. The cost of care is an increasing concern and is an area that patients and families are frequently uncomfortable discussing. This often results in conflicts that are identified only late in the course of care. Distressing issues may arise concerning long-term care and, particularly, the distribution of financial support and caregiving responsibilities among family members. Whenever possible, prompt initiation of family conferences or referrals to social workers are advisable.

Providing a Sense of Control

Helping chronically and terminally ill patients regain a sense of control is a key element in managing the helplessness many patients experience. Within the acute and long-term care settings, “power symbols” exist that shift the locus of control away from the patient. These symbols include the sea of white coats, high-tech equipment, hospital beds that place patients below their professional caregivers, and a general lack of privacy. Interventions that can promote a sense of control in the outpatient setting include allowing patients to remain dressed during most office calls, at least until an examination is required; reducing the clinical, white-coat formality; and providing a safe, nonthreatening, private place for meetings with patients and their families. These accommodations return a sense of control and dignity to the patient with a terminal illness and promote health and well-being. Another critical component of providing a sense of control is having an active patient education component. Giving patients and families the knowledge tools that they need to make decisions is a great empowerment. Practical information regarding how to “negotiate the system,” how to get help after hours, and how to communicate with health care professionals in a way that gets them the information they need are all important components of patient education.

Tuning In to Distress

Psychological and spiritual health are often profoundly affected by life-threatening illness. In fact, patients with chronic and terminal illnesses display a high incidence of frank psychiatric morbidity, documented in several studies to range from 40% to 53%. Common psychiatric diagnoses among the terminally ill include delirium, amnesia, major depression, and anxiety. However, many patients with significant symptoms of anxiety, depression, and anger do not qualify as having a major psychiatric illness. These symptoms have been described throughout the palliative care literature as distress. Identifying distress early in the palliative care continuum allows for early intervention, prevention of comorbid psychological problems, and improved quality of life.

Easy-to-use, inexpensive, brief, noninvasive, and generally well accepted self-reporting questionnaires can be used in the outpatient setting. Two good examples are the Hospital Anxiety and Depression Scale (HAD) and the Distress Thermometer. The HAD consists of 14 questions to which the client answers yes or no. This tool omits somatic complaints and focuses on questions that can help differentiate anxiety and depression. Despite its title, it has also been successfully used in the outpatient setting.

The Distress Thermometer has been tested in men with prostate cancer. It consists of a visual analogue scale made to look like a thermometer, with the bottom of the thermometer reading 0, or no distress; 5 being moderate distress, and 10 (at the top of the thermometer) being extreme distress. Distress is defined in a generic sense of unpleasant stress. This is
a simple scale that can be used at the beginning of each office visit or on a regular basis (e.g., quarterly). Responses can be used to open discussions of the symptoms of distress being experienced by a client in the outpatient setting. For example, the clinician may say, “I see that you’re feeling a moderate amount of distress. Can we talk about what you’re feeling?”

Spiritual distress can be equally devastating to the patient and family. Hearing “What did I do to deserve this?” or “How could God let this happen to my husband?” from a patient or family member is a cue that spiritual support is needed. Some healthcare systems have chaplains available in the outpatient setting. Many churches and synagogues provide outreach ministries to the gravely ill. Other nontraditional means of spiritual support include meditation and rituals to explore the meaning of events. Whenever possible, the clinic should be given a list of community resources for spiritual support.

The Three C’s of Outpatient Palliative Care: Cooperation, Communication, and Closure

At the heart of palliative care in the outpatient setting are the three concepts of cooperation, communication, and closure. The concepts of cooperation and communication are woven throughout this chapter. The outpatient setting is the site of cooperation among patient, family, and outpatient staff. This cooperation expands to the agencies within the community that are caring for the patient. This may include home health care nurses, long-term care staff, local pharmacists, neighbors, and friends of the client, and the local church. The physician and advanced practice nurses cooperate to provide easy access to care. The specialist and primary care physician, who both often monitor the patient in the outpatient setting, cooperate. Care in the outpatient setting is not provided in isolation, but by a well-coordinated and dedicated community team.

At the heart of this cooperation is good communication. Communication begins with active listening, fostered in the outpatient setting. Efficient and accurate documentation of patient teaching, telephone calls, and interventions is the key to continuity of care. A variety of tools have been developed for use in the outpatient setting to improve this communication.

Not yet addressed, but also important in the outpatient setting, is closure. Bereavement is an issue for nurses, physicians, and staff in the outpatient setting. As patients become sicker and eventually homebound, the outpatient staff is no longer able to see the patients, despite being in close contact with family and home care staff over the telephone. In many cases, this early separation from the patient complicates the ability of the outpatient staff to come to closure with what often has been a long-term relationship with the patient. This abrupt loss of connection can be a significant source of bereavement for staff.

Outpatient nurses may have had years to assess the family or caregivers’ previous experiences with death, the support available, and the coping resources of those who have suffered the loss. This familiarity with the family or caregiver helps the nurse in the outpatient setting provide better support to grieving loved ones.

Often, family members or caregivers are drawn back to the outpatient setting to say final good-byes or give gifts of thanks to staff members who may have become as close as family to the patient and caregivers. Staff should be prepared for this visit by being informed of the patient’s death. Work should stop for a moment to embrace the returning family members and give them time to tell the story of the death and share feelings of grief and joyful memories of the deceased. Gifts or pictures brought by the family should be accepted graciously. Many offices take time out each month to send cards to families of patients who have died.

Staff of the outpatient clinic, the front desk receptionist, the medical assistant, the nurse, and the physician may experience grief after the loss of a patient. Often, staff require support through the deaths of patients dear to them. It is important to allow for special opportunities to celebrate the lives and mourn the deaths of these patients. Attending funerals, keeping scrapbooks, and having occasional symbolic tributes to patients can help staff through the grieving process. Occasionally, it may be helpful to provide professional counseling or to send staff members on a retreat, where feelings regarding death and loss can be shared. Caregivers, as well as family and friends, need closure when death comes. In the outpatient setting this affords all who have experienced the loss support on the journey toward healing.

Summary

The outpatient setting has both advantages and disadvantages. As more and more patients with end-stage disease choose to remain in their homes, the outpatient clinic has become the main point of contact for care and coordination of resources. The outpatient clinic staff act as gatekeepers, maintaining checks and balances on the home health care system or the long-term care facility. Relationships are developed over many years, creating a sense of trust that fosters the holistic care that is at the heart of palliative medicine.

Strategies for providing palliative care in this setting apply to all diseases. The concepts of active listening, promoting patient control, assessing for distress, and promoting access to care all improve the delivery of palliative care in the outpatient clinic. The use of nurse-staffed telephone triage systems, nurse practitioners, and tools for assessing palliative care needs benefits both the terminally ill patient and the patient with advanced chronic disease. Care algorithms and critical pathways assist staff in implementing research-based interventions to prevent suffering and promote quality of life. Finally, the three C’s of outpatient palliative care emphasize the necessity of coordination, communication, and closure.

There is perhaps a fourth quality needed when caring for chronically or terminally ill clients in the outpatient setting—commitment. Through a commitment to alleviate suffering
and promote quality of life, caregivers in the outpatient setting assist patients in finding physical, psychological, and spiritual wellness, even at the end of the disease trajectory.

Rehabilitation and Palliative Care

I may have cancer, but I have a lot of livin’ to do before I go. I have kids to take care of, a house, a job. I have faith that these drugs will help and even if I don’t live forever, I still have some livin’ to do now and a lot of things to take care of. So I want everything they got to make me strong.
—A patient

Key Points

- Rehabilitation principles are applicable to palliative care to enhance quality of life.
- Interdisciplinary care is a key concept in rehabilitation.
- Rehabilitation in palliative care can prevent disability and complications.

Even when it is not reasonable to expect cure or reversal of disease processes, or to restore a previous level of functioning and independence, a rehabilitative approach to nursing care adds quality to the experience of life’s completion. Grounded in respect for each unique patient, rehabilitation nurses address palliative and end-of-life care with concern for preserving hope, human dignity, and autonomy. They involve social, spiritual, and functional support systems. Rehabilitation nursing interventions are designed to help patients and families make the most out of each day in the context of the disease trajectory. The language of rehabilitation nursing is a language shared with those who practice palliative care.

Rehabilitation nurses work with the concepts of independence and interdependence, self-care, coping, access, and quality of life, skillfully weaving them into the assessment, planning, implementation, and evaluation of nursing care. Although the focus is on function, fundamental to this practice is the acceptance of varieties of life experiences, including those at life’s end.

This chapter applies concepts of rehabilitation to palliative care across settings. Case studies are presented to demonstrate the application of palliative care to patients, even those with life-threatening illnesses. Finally, numerous strategies are discussed for use of rehabilitation techniques to prevent disability and complications in advanced disease.

Rehabilitation Nursing

Rehabilitation nursing in any context concerns itself with adaptation. As life proceeds to its end, adaptation to a new state allows beings to remain whole: to interact with their environments, to experience human relationships, and to achieve personally meaningful goals. Rehabilitation nurses find themselves at work in every phase of growth, development,
and dying, as individuals strive to adapt across the continuum of life.

Rehabilitation nurses care for persons with incurable progressive disease states in a variety of settings. Whether care is patient-, provider-, or facility-centered, the merging of rehabilitation and palliative nursing principles is evident.

Acute comprehensive inpatient rehabilitation units are set up in such a way that complex medical-surgical issues may be managed concurrently with the functional processes of comprehensive rehabilitation. For example, patients with metastatic cancer affecting their bones may have significant care needs related to mobility and activities of daily living, well addressed in an inpatient rehabilitation setting.

For many patients with terminal illness, the transition to an acute rehabilitation unit represents a crucial point in their healthcare experience. It is a time when the future comes into focus, and goals are defined based on the likely disease progression. Sometimes a short stay on an inpatient rehabilitation unit makes it possible for patients to return to a home setting, because of the gains in independent function that may be realized. Patients and family members may begin to face limited prognoses, decline in abilities, and changes in roles. Through an interdisciplinary therapeutic process, care needs are clarified, and skills and adaptation strategies are taught to patients and those who will care for them outside of the hospital.

Subacute rehabilitation facilities provide additional therapy activities, such as physical, occupational, or speech therapy, based on patient need, endurance, and tolerance. The pacing and amount of therapy are gauged according to individualized goals. As in comprehensive inpatient rehabilitation units, the aim is to facilitate improved physical function and as much independence as possible, even as the disease process moves the patient toward death. For example, patients with advanced disease who are too frail to participate in a full acute rehabilitation program may benefit from the slower-paced rehabilitation of a subacute setting.

Long-term care settings, such as skilled nursing facilities, are often places where lives are completed. Specialized geriatric facilities focus on the care needs of aging persons, often requiring specialized rehabilitation interventions. In both of these settings, rehabilitation nurses may plan and direct care delivery and make sure that patient and family concerns are kept in the forefront. Attention is paid to optimizing function and self-care, as well as addressing physical care issues.

Hospice settings may also provide a venue for a rehabilitative approach to end-of-life care. Careful planning of care to take into account limitations, yet promote function and autonomy, is a key factor in smoothing the transition to an inevitable death. Rehabilitative techniques and strategies make it easier for caregivers to manage increasing deficits, thereby protecting patient comfort and dignity through the dying process.

Pediatric rehabilitation is focused on guiding the development of children to minimize disability and handicap that may result from physical or cognitive impairment. There are situations in pediatric rehabilitation in which palliative care comes into play, and efforts are directed toward enhancing the normal function of both patient and family through the course of disease. For example, the family members of a child with progressive neuromuscular disease may learn how to use adaptive devices to position the child in a wheelchair for comfort and social interaction as well as for physiological function.

In the insurance industry and managed care systems, rehabilitation nurses have the opportunity to advocate for the needs of persons with disease or disability and to reduce barriers to their access to care and resources. Near the end of a terminal disease course, planning and resource management are essential to ensure optimal care without undue economic and emotional burdens to families. Case management is an expanding practice area for rehabilitation nurses, usually with multidisciplinary relationships. Because palliative care needs are unique to individuals and require coordination of the care across disciplines, usual or episodic patterns of delivery and resource use may prove inadequate. The implementation of care pathways in palliative care requires careful and compassionate guidance and evaluation, tailored to meet individual strengths, abilities, needs and preferences.

Finally, care of dying patients occurs frequently at home. Successful end-of-life care at home is the preference of many patients and families. Such care depends on skill, concern, keen assessment, and creative problem-solving. For the reasons shown in each setting, rehabilitation nursing is well suited to this charge.

Rehabilitation Nursing and Palliative Care

Rehabilitation nursing adds value in the arena of palliative care. As future health care services center on needs, preferences, and informed consent of patients and families in our society, there is less emphasis on cure, illness, paternalism, and prescription. More attention is directed to self-care and client participation, holistic wellness, primary care and prevention, and the quality attributes of care as defined by the consumer.

Patient/family-centered care is clearly appropriate for the unique experience of dying. Enabling a kind of wellness to exist even at the point of death, such as the experience of a “good death,” fits with the rehabilitation philosophy. Many rehabilitation nursing actions center on supporting physiological function and preventing complications, goals that are still appropriate at the end of life. Finally, rehabilitation has long been concerned with understanding and measuring quality of life, whether related to physical, psychosocial, or spiritual domains.

The real value of a rehabilitative approach to the nursing care of persons with declining health states lies in the foundations of rehabilitation nursing practice. As defined by the Association of Rehabilitation Nurses in 2004, rehabilitation nurses...
• Attend to the full range of human experiences and responses to health and illness
• Deal with families coping with lifelong issues
• Provide a holistic approach to care
• Facilitate team dynamics and integration
• Educate patients and their families to help them control and manage a wide range of challenges associated with chronic illness or disability
• Form partnerships with patients and other health care providers to attain the best possible outcomes

The hallmark of rehabilitation is interdisciplinary collaboration. The synergy of collaboration enhances the value of rehabilitation nursing interventions and ensures that patient needs are addressed from a variety of perspectives. Typically, the rehabilitation team consists of physicians with specialized training in Physical Medicine and Rehabilitation; rehabilitation nurses; physical, occupational, speech, respiratory, and recreation therapists; exercise physiologists; dietitians; social workers; and others as required to address particular needs (Table 45–1). Effective teamwork requires mutual understanding and synchrony of the roles and responsibilities of each member. When the rehabilitation team works in synergy, it serves patients and families across the continuum of life.

**Conceptual Framework**

It is a common view that rehabilitation has a place somewhere between curative and palliative care. Rehabilitation seems not really to fit with curative processes, where care issues resolve with specific treatments and patients’ levels of function and independence ultimately return to normal. Nor does rehabilitation seem in keeping with the irrevocable progress toward death, because rehabilitation implies a return to a previous way of living through adaptation. However, rehabilitation has concerns at each point of the continuum from wellness to death. In wellness, the concern is to prevent health problems and reduce factors that might lead to illness and disability. At the end of life, the concern is to promote autonomy and dignity by enhancing function and independence as much as possible.

To conceptualize how rehabilitation nursing fits with care at the end of life, it is helpful to consider a diagrammatic representation (Figure 45–1). In this diagram, curative and palliative care are pictured as two discrete spheres. Rehabilitation overlaps both substantially. In each sphere there is a place for rehabilitation. At the junction between curative and palliative care, rehabilitation may find its greatest impact.

**Rehabilitation Principles Applied to Palliative Care**

The rehabilitation of patients with palliative care needs should begin as early as possible. As soon as functional deficits are observed or anticipated, appropriate consultation with members of the rehabilitation team should be initiated. Certain diagnoses, such as progressive neuromuscular diseases; malignancies affecting the brain, spinal cord, or skeletal system;

organ failure; and many other conditions that result in functional impairments, should trigger mobilization of the rehabilitation team.

The goals of rehabilitation are to prevent secondary disability, to enhance the functions of both affected and unaffected systems, and to help patients adapt to their physical and social environments by means of physical restoration and adaptive devices.\(^6\)

Rehabilitation nursing strategies focus on:
- Caring for whole persons in their social and physical environments
- Preventing secondary disability
- Enhancing function of both affected and unaffected systems
- Facilitating use of adaptive strategies
- Promoting quality of life

To illustrate the rehabilitation strategies as they may be applied in actual palliative nursing care situations, some case studies are offered. The stories serve to illuminate the role of rehabilitation nursing in palliative care and represent issues in common with many rehabilitation patients.

---

**Caring for Whole Persons in Their Social and Physical Environments**

Appreciating each person as a unique individual is extremely important to the rehabilitation process. Whereas it may be evident to rehabilitation professionals that certain goals and interventions would suit the patient's needs, even more important is finding congruence with the patient's own perceived and stated goals and values.

---

**Case Study**

*Edna W, a 60-Year-Old Woman with a Lung Transplant*

With a history of rapidly worsening chronic obstructive pulmonary disease, 60-year-old Edna W was faced with few options. As every breath became a struggle, she wondered how she could go on with her life and whether it was worth continuing the fight. She had already lost so much of what was important to her: mobility, independence, and social relationships. Now she found herself homebound, exhausted, and unable to carry on even a telephone conversation with friends and family she so cherished.

After much consultation and deliberation, she agreed that lung transplantation was the only course of treatment that would afford her the function and independence she believed made her life worthwhile. She received the transplanted lungs after a relatively short wait. But her expectations of returning to wellness were not to be fulfilled. Ms. W began an extraordinarily complicated postoperative course and a journey that would lead her to a life's end on which she had not planned.

Initially, Ms. W required prolonged ventilatory support. She struggled with infection and rejection of her new lungs. She experienced shock, sepsis, distress; her records thickened with stories of heroics and near misses, of technology, of miracles, of persistent argument with fate. She had established with her family that she would want everything possible done to preserve her life, and thus the critical balancing act went on for months. Just as her condition seemed to be stabilizing, she had a massive stroke, resulting in dense hemiplegia and loss of speech/language function.

She was admitted to the inpatient rehabilitation medicine service to focus on mobility, self-care, and speech functions in order to help her to return home with her family. She progressed very slowly, with numerous complications related to her pulmonary status, immunosuppression, and cardiovascular deterioration.

A second stroke left her with even more-limited language and cognitive function. She required maximum assistance for all activities of daily living, and she ceased to make progress toward her rehabilitation goals. Her pulmonary function declined. Her family recognized that they would not be able to meet her care needs at home. Further evaluation of her lungs revealed that she had developed a lymphoma, for which, in her case, no treatment could be offered. Her prognosis plummeted, with the likelihood of death in a matter of weeks.

The focus of her rehabilitation care shifted. No longer would it be reasonable to expect her to reach the level of independence she would need to return home. A rigorous exercise program was not going to change the trajectory of her disease and in fact might sap her energies and contribute to more frustration and discomfort.

By talking with family and friends, the rehabilitation team learned that Ms. W was strong-willed, stubborn, difficult, but deeply loved. She was seen as the matriarch of the family. For most of her adult life, she had balanced her responsibilities as a single parent with her work as a postal clerk. She was characterized as determined and cantankerous, impatient, critical, and quick to frustrate. Her family was close and extremely important to her. She had a wide circle of friends. Her four sons took turns visiting her in the hospital and sincerely wanted to get her back home again.

With these facts in mind, the rehabilitation team designed communications and interventions that took into account the personal traits and values that were particular to Ms. W. They knew that she would have difficulty tolerating frustration. They knew that she would need to feel in control as much as possible. They also knew that involvement of her family and friends would be essential. They anticipated the effects of prolonged stress on the family unit and recognized the profound loss the family would sustain as her life concluded.

Rehabilitation nursing actions focused first on communication. Because of her dense aphasia, she was unable to verbalize her thoughts or feelings. Instead, she perseverated on one word, growing increasingly agitated when people...
were unable to understand her. A speech therapist was involved in setting up nonverbal methods of communication, such as picture boards. As the nursing staff worked with Ms. W, they tuned into behavioral cues and expressions. Family members also helped in the interpretation of her attempts to communicate. Strategies for communication included:

- Direct eye contact
- Relaxed, unhurried approach
- Slow, distinct phrases in normal tone of voice
- One thought presented at a time
- Time allowed to process information
- Gestures to convey and clarify meaning

Efforts were directed toward maintaining her comfort and dignity. Whenever possible, she was supported in making her own choices. Occupational and physical therapies concentrated on interventions that would promote her autonomy. Functional activities, such as dressing, grooming, and eating, allowed her opportunities to exercise her independence. Access to her physical environment was accomplished through the use of adaptive devices and wheelchair mobility skills. As her condition deteriorated, it was more difficult to ascertain her desires. Inclusion of family members became more important, both for carrying out her wishes as they knew them and for giving the family the active role in her care that they wanted.

Throughout the course of Ms. W’s final illness, spiritual and psychosocial support were priorities. With her ability to communicate so severely impaired, her needs for support might have been misunderstood or overlooked. She was suddenly unable to serve as the source of stability and strength for her family, and roles and expectations were greatly changed. The rehabilitation nurses, the psychologist, the social worker, and the chaplain worked together to counsel and care for both patient and family.

When death came, the family described a mixture of feelings of relief, sorrow, and satisfaction. Through their sadness, they recognized the efforts of the rehabilitation team to preserve Ms. W’s uniqueness and integrity as a human being. Thus, they would remember her.

### Preventing Secondary Disability

Whatever the disease process, persons in declining states of health are at risk for development of unnecessary complications. Even at the end of life, complications can be prevented, thereby enhancing a person’s comfort, function, independence, and dignity. Treatment of one body system must not compromise another. For example, patients who are bed bound are at risk for development of muscular, vascular, integumentary, and neurological compromise, which could result in secondary disability.

### Enhancing Function of Both Affected and Unaffected Systems

A chief concern in rehabilitative care is enhancing function of both affected and unaffected body systems, thereby helping patients to be as healthy and independent as possible. In palliative care, many care issues involve the interconnections of body systems and the need to enlist one function to serve for another.
Case Study
Mr. O’Neill, a Man with Metastatic Prostate Cancer

Paul O’Neill had been a successful attorney for 30 years. A burly, loud-spoken Irishman, he prided himself in bringing life and laughter everywhere he went. Although diagnosed and treated for prostate cancer, he never slowed the hectic pace of his law practice or his busy social calendar. In fact, he had little time to pay attention to the ominous symptoms that were developing that indicated the advance of his disease.

When he sought medical attention at last, the cancer had metastasized to his spine, resulting in partial paralysis and bowel and bladder impairment. Orthopedic spine surgeons attempted to relieve pressure on his spinal cord with the hope of restoring motor and sensory function. However, when they performed the surgery, they found that the cancer had spread extensively, and they were unable to significantly improve his spinal cord function. Radiation followed, but it had little effect on the spreading cancer.

Mr. O’Neill was stunned. He could not believe the turn his life had taken. Suddenly, nothing seemed to work. He had to depend on others for the first time in his life. He felt like “some kind of freak,” unable to move his legs or even manage normal bodily functions. His bulky frame became a heavy burden as he tried to relearn life from a wheelchair. He wrestled with the unfairness of the situation, finally promising himself that he would “go out in style.” He wanted to get home as soon as possible, so as not to waste his precious remaining time.

Mr. O’Neill spent 12 days on the inpatient rehabilitation unit, then transitioned to home with continued therapies and nursing care. He died 2 months later, at home with his family present.

In Mr. O’Neill’s case, several body systems were at risk for complications, although not all were directly affected by the disease process. Mobility was a critical concern. Bowel and bladder management also presented challenges. His neurological deficits and rapidly progressing disease, combined with his size and the need to learn new skills from a wheelchair level, placed him at risk for development of contractures, skin breakdown, and deep vein thrombosis. Problems with bowel and bladder function put him at risk for constipation, distention, and infection. He experienced severe demoralization. In keeping with his wishes, the rehabilitation nursing staff designed a plan for Mr. O’Neill and his family to follow at home.

Priority rehabilitation nursing issues included

- Managing fatigue related to advancing disease
- Pain control
- Promoting mobility and independence
- Managing neurogenic bowel and bladder
- Alleviating social isolation related to the effects of terminal illness
- Anticipatory grieving and spiritual care

Managing Fatigue Related to Advancing Disease

The rehabilitation team planned Mr. O’Neill’s care to protect his periods of rest throughout the day. They knew that his therapy would be more effective and his ability to carry over new learning of functional activities would be better if he were in a rested state. His sleep–wake cycle was restored as quickly as possible. Occupational therapists taught him strategies for energy conservation in his activities of daily living, including the use of adaptive devices, planning, and pacing.

Pain Control

Mr. O’Neill initially described his pain as always with him, dull and relentless, wearing him down. Rehabilitation nurses evaluated his responses in relation to different medications and dosage schedules, as well as nondrug pain control interventions such as positioning and relaxation. The most effective method of pain control for Mr. O’Neill was scheduled doses of long-acting morphine, coupled with short-acting doses for breakthrough or procedural pain. This method of pain management is frequently used in rehabilitation settings, because it does not allow pain to become established, and the patient does not have to experience a certain level of pain and then wait for relief. It also minimizes sedative effects. With his pain under better control, Mr. O’Neill was able to actively participate in his own care and make deliberate decisions about his goals.

Promoting Mobility and Independence

Bed Positioning

Positioning and supporting of the body in such a way that function is preserved and complications are prevented is an important consideration in mobility. As Mr. O’Neill’s disease progressed and he experienced increasing weakness and fatigue, he spent more and more time in bed. Teaching of patient and family focused on the techniques of bed mobility and specific precautions to prevent complications.

Supine lying was minimized because of Mr. O’Neill’s high risk for sacral skin breakdown. Even with a pressure-reducing mattress, back-lying time needed to be restricted. To reduce shearing forces, the bed was placed in reverse Trendelenburg position to raise the head, rather than cranking up just the head of the bed. Draw sheets were used to move Mr. O’Neill, again to prevent shearing. Shearing is a force generated when the skin does not move as one with the structures beneath it. Stretching and breakage of capillaries and subcutaneous tissues contributes to the potential for deep skin breakdown.

Positioning of the lower extremities is important to prevent complications such as foot drop, skin breakdown, contractures, and deep vein thrombosis. When the patient is supine, care should be taken to support the feet in neutral position. This can be accomplished by using a footboard or box at the end of the bed or by the application of splints. Derotation splints were placed on Mr. O’Neill’s lower legs to keep his hips in alignment, to prevent foot-drop contractures, and to reduce the risk of heel breakdown. Range-of-motion exercises were done at least twice daily.
When Mr. O'Neill was side-lying, pillows were employed to cushion bony prominences and maintain neutral joint position. His uppermost leg was brought forward, and the lower leg was straightened to minimize hip flexion contractures. Frequently overlooked as a positioning choice, prone lying offers advantages not only of skin pressure relief and reduction in hip flexion contractures, but also in promoting greater oxygen exchange. Mr. O'Neill's bed position was alternated between back, both sides, and prone at least every 2 hours.

**Sitting**

There are many physiological benefits of upright posture. Blood pressure, digestive and bowel functions, oxygenation, and perception are geared toward being upright. Weight-bearing helps to avert skeletal muscle atrophy. Sitting, standing, and walking provide for changes in scenery and enhance the ability to socialize. This was an important consideration for Mr. O'Neill, who experienced emotional distress at the social isolation his illness imposed.

It is important to choose seating that supports the patient, avoiding surfaces that place pressure on bony prominences. A seat that is angled back slightly helps keep the patient from sliding forward. Placing the feet on footrests or a small box or stool may add comfort, as may supporting the arms on pillows or on a table in front of the patient. Sitting time should be limited, based on patient comfort, endurance, and skin tolerance. Mr. O'Neill followed a sitting schedule that increased by 15 minutes a day until he was able to tolerate about 2 hours of upright time. That was enough time to carry out many of his personal activities, yet not so much as to overly tire him.

Planning for Mr. O'Neill's return home involved careful assessment of his equipment needs. Physical and occupational therapists conducted a home evaluation to determine how he would manage mobility and self-care activities and what equipment would be appropriate. Family members practiced using equipment and devices under the guidance of the rehabilitation team. The objective was to simplify the care as much as possible, while still supporting Mr. O'Neill's active participation in his daily activities.

Examples of home care equipment often used include commodes, wheelchairs, sliding boards, Hoyer lifts, adaptive devices such as reachers, dressing sticks, long-handled sponges, tub/shower benches, hospital beds, and pressure-relieving mattresses. Examples of home modifications include affixing handrails and grab bars, widening doors, using raised toilet seats, and installing stair lifts and ramps.

**Management of Neurogenic Bowel and Bladder**

For Mr. O'Neill, the loss of bowel and bladder function was especially distressing. It placed him in a position of dependence and impinged on his privacy. It reinforced his feelings of isolation and being different. The focus of rehabilitation nursing interventions was to mimic the normal physiological rhythms of bowel and bladder elimination. By helping Mr. O'Neill gain control of his body functions, nursing staff hoped to promote his confidence, dignity, and feelings of self-worth.

Bowel regulation and continence were achieved by implementing a classic bowel program routine. Mr. O'Neill was especially prone to constipation due to immobility and the effects of pain medications. The first intervention was to modify his diet to include more fiber and fluids. He also took stool softener medication twice daily. His bowel program occurred after breakfast each morning, to take advantage of the gastrocolic reflex. He was assisted to sit upright on a commode chair. A rectal suppository was inserted, with digital stimulation at 15-minute intervals to accomplish bowel evacuation. The patient and his wife were taught how to manage this program at home. Although reluctant at first, Mr. O'Neill became resigned to the necessity of this bowel program and worked it into his morning routine. His wife, eager to help in any way she could, also learned the techniques. Once a regular pattern of elimination was established, Mr. O'Neill no longer experienced incontinence.

For bladder management, nursing staff implemented a program of void trials and intermittent catheterization. The patient learned to manage his own fluid intake and to catheterize himself at 4-hour intervals, thereby preventing overdistension or incontinence. However, as his disease progressed, he opted for an indwelling urinary catheter because it was easier for him to manage. There is a continuous need to evaluate and individualize rehabilitation goals, and to alter goals as patients experience more advanced disease.

**Alleviating Social Isolation Related to the Effects of Terminal Illness**

With a history of active social involvement, Mr. O'Neill had great difficulty with the limitations his disease imposed on his energy level and his ability to remain functional. He did not want others to see him as incapacitated in any way. He did not want to be embarrassed by his failing body. The rehabilitation team concentrated on solving the physical problems that could be solved. A recreation therapist assessed his leisure and avocational interests and prescribed therapeutic activities that would build his confidence in social situations. Together, the team helped him learn to navigate around architectural barriers and helped him to practice new skills successfully from a wheelchair level.

**Anticipatory Grieving and Spiritual Care**

Mr. O'Neill concentrated on making plans and settling financial matters in preparation for his death. He continued to set goals for himself and to maintain hope, but the nature of his goals shifted. Initially, he was concerned with not becoming a burden to his family and focused on his physical functioning. As his mobility and endurance flagged and he had to rely more on others for assistance with basic care needs, he began to change his goals. Some of his stoicism fell away. He revealed his feelings more readily and described the evolution of his emotions. Now the focus became his relationships: an upcoming wedding anniversary, a son's graduation from law school. Rehabilitation nurses, home care nurses, the psychologist, and the social worker supported the
patient and his family as they began to grieve the past that would never return and the future that was not to be. Pastoral care was a significant part of the process, as Mr. O’Neill struggled with spiritual questions and sought a peaceful understanding of what was happening to him. The rehabilitation team endeavored to help the patient live all the days of his life, by helping body and soul continue to function.

Facilitating Use of Adaptive Strategies

The ability of patients to continue to participate actively in living their lives has much to do with successful adaptation to changes in function. Even at the end of life, a patient’s capacity to adapt remains. Everyday activities may become very difficult to perform with advancing disease. However, rehabilitation nursing actions that promote communication, the use of appropriate tools and equipment, family participation, and modifications to the environment all enhance the process of adaptation.

Communication

Opening the doors to communication is the most important rehabilitation nursing intervention. By removing functional barriers to speech, by teaching and supporting compensatory strategies, and by allowing safe opportunities for patients and families to discuss difficult issues around death and dying, rehabilitation nurses perform a critical function in the adaptation process.

Tools and Equipment

Many adaptive devices are available to patients and families that enhance functional ability and independence. Rehabilitation offers the chance to analyze tasks with new eyes and solve problems with creativity and individuality. Examples of useful tools to assist patients in being as independent as possible include reachers, dressing aids such as sock-starters, elastic shoelaces, and dressing sticks. For some patients, adapted eating utensils increase independence with the activity of eating and thereby support nutritional intake. Modifications to clothing may permit more efficient toileting and hygiene, conserving both energy and dignity.

Family Participation

As illustrated in the previous case studies, the involvement of family and friends has multifaceted benefits. Because of the social nature of humankind, presence and involvement of family and friends has great importance at the end of life. Family members may seek involvement in the caring activities as an expression of feelings of closeness and love. They may try to find understanding, resolution, or closure of past issues. For the person at the end of life, the presence of family, friends, and even pets may be a powerful affirmation of the continuity of life.

Modifications to Environment

Rehabilitation professionals are keenly aware of the effect of the environment of care on function, independence, and well-being. The physical arrangement of furnishings can be instrumental, not only in promoting patient access to the environment, but also in the ease with which others care for the patient. The environment can be made into a powerful tool for orientation, for spatial perception, and for preserving a territorial sense of self.

Light has a strong effect, not only on visual perception, but also on mood and feelings of well-being. Light can be a helpful tool in maintaining day–night rhythms and orienting patients to time and place. Sound is also an important environmental variable. For example, music has been implicated as a therapeutic intervention in both rehabilitation and palliative care.

Promoting Quality at the End of Life

The concept of quality of life is linked to function and independence. Patients often describe their satisfaction with life in terms of what they are able to do. Important determinants of quality of life include (1) the patient’s own state, including physical and cognitive functioning, psychological state, and physical condition; (2) quality of palliative care; (3) physical environment; (4) relationships; and (5) outlook. Rehabilitation zeroes in on the essential components of mobility, self-care, cognition, and social interaction, which define what people can do.

Case Study

LN, a 42-Year-Old Woman with a Malignant Brain Tumor

LN, age 42, had just started her own consulting business when she began to experience headaches and visual disturbances. At first, she attributed her symptoms to the long hours and stress related to building her business. But when she experienced weakness of her left side, she knew that something more serious was happening.

She had a glioblastoma multiforme growing deep in her brain. Surgery was performed to debulk the tumor, but in a matter of weeks it was clear that the mass was growing rapidly. A course of radiation was completed to no avail. Her function continued to decline, and it seemed that every body system was affected by the advancing malignancy. Now her left side was densely paralyzed, she had difficulty swallowing and speaking, and her thinking processes became muddled.

Her family was in turmoil. On one hand, they resented the disruption her sudden illness imposed on their previously ordered lives. On the other hand, they wanted to care for her and make sure that her remaining time was the best that it could be. As they watched her decline day by day, ambiguities in their relationships surfaced, and conflicts about what would define quality of life emerged.
Rehabilitation's part in promoting quality of life at the end of life is several-fold. Rehabilitation is a goal-directed process. Realistic, attainable goals based on the patient's own definition of quality of life drive the actions of the team. In the area of physical care, rehabilitation strategies support energy conservation, sequencing and pacing, maintaining normal routines, and accessing the environment. Beyond that, rehabilitation nurses facilitate effective communication and problem-solving with patients and families. They offer acceptance and support through difficult decision-making and help mobilize concrete resources.

When rehabilitation nurses approach care, it is with the goal of enhancing function and independence. In LN's case, the brain tumor created deficits in mobility, cognition, and perception. Also, more subtle issues greatly influenced the quality of her remaining time. It was important to understand how the patient would define the quality of her own life and to direct actions toward protecting those elements.

Promoting Dignity, Self-Image, and Participation

LN's concept of quality of life was evident in how she participated in her care and the decisions that she made about her course of treatment. The rehabilitation team learned that LN's mother had died several years earlier of a similar brain tumor. Caring for her mother had solidified her beliefs about not wishing to burden others. Part of LN's definition of quality of life was that she would not be dependent on others.

LN prided herself on being industrious and self-sufficient. To her, the ability to take care of herself was a sign of success. Rehabilitation nurses and therapists focused on helping to manage symptoms of advancing disease so that she would be able to do as much for herself as possible. This included adaptive techniques for daily living skills, pain management, eating, dressing, grooming, and bowel and bladder management. Even with her physical and cognitive decline, retaining her normal routines helped to allay some feelings of helplessness and to promote a positive self-image.

Control, Hope, and Reality

As her illness progressed, LN felt she was losing control. It became difficult for her to remember things, and expressing herself became more laborious and frustrating. She slept frequently and seemed disconnected from external events. Her family understood her usual desire for control and made many attempts to include her in conversations and to support her in making choices.

At first, her concept of hope was tied to the idea of cure. Radiation therapy represented the chance of cure. When that was completed without appreciable change in her tumor, some of her feelings of hopefulness slipped away. She sank into a depression. Her family was alarmed: LN's psychological well-being was a critical component in her own definition of quality of life. Treating her depression became a priority issue for the rehabilitation team. Through a combination of rehabilitation psychological counseling and antidepressant medications, her dark mood slowly lifted. Hope seemed to return in a different form, less connected to an event of cure and more a part of her interactions with her daughter and sister.

Family Support

Another significant area that related to quality of life for LN had to do with social well-being. She struggled with the idea of becoming a burden to her family and realized that she was losing control over what was happening to her. Her relationships with others in her life were complex, and now they were challenged even further. At the same time, her family members wrestled with memories of the mother's death and feared the responsibilities for care that might be thrust upon them.

The rehabilitation team tried to help the patient and her family work through their thoughts, feelings, and fears, and helped them to find ways to express them. The team arranged several family conferences to discuss not only the care issues but also the changes in roles and family structure. Whenever possible, the team found answers to the family's questions and made great effort to keep communications open. Creating safe opportunities for the family to express their ambivalence and conflict helped move them toward acceptance. The family was able to prepare in concrete ways for the outcome they both welcomed and dreaded.

Understanding Outcomes

In rehabilitation, there is a strong emphasis on the measurement of patient outcomes. Since the 1950s, many functional assessment instruments have been developed and used to help quantify the changes that occur in patients as a result of care.
and recovery. Some instruments to measure functional and physical outcomes are applicable to the assessment of patients within the last month of life.

There are more than a dozen functional outcome measurement tools in common use in rehabilitation settings in the United States and Canada (Table 45–2). Measurement of self-care and mobility are central to rehabilitation, but the functions and behaviors required to lead a meaningful life are much broader. They may include cognitive, emotional, perceptual, social, and vocational function measurements as well.

For measuring function in the last 30 days of life, three scales may be particularly useful. The Rapid Disability Rating Scale (RDRS-2)\(^11\) has a broad scope to include items related to activities of daily living, mental capacity, dietary changes, continence, medications, and confinement to bed. The Health Assessment Questionnaire (HAQ)\(^12\) is a widely used instrument that summarizes the patients’ areas of major difficulty. The Functional Independence Measure (FIM) is an ordinal scale that quantifies 18 areas of physical and cognitive function in terms of burden of care.\(^13,14\) These scales are appropriate to palliative care because they focus on specific aspects of function that relate to patients’ independence. The scales may be used to determine whether interventions at the end of life serve to foster independence and function for as long as possible.

There is also strong interest in the field of rehabilitation in measuring patients’ perceptions of quality of life. When the measured domains are considered, the connection between rehabilitation and end-of-life care becomes evident. Most of the measurements of quality of life have to do with physical, cognitive, social, and spiritual function, the chief concerns of the rehabilitation practitioner (Table 45–3).

Outcome measurements matter because they can reveal a lot about the quality of life experienced by persons near the end of life. For example, by assessing at intervals, it is possible to determine how much function patients retain as they approach death. By identifying and measuring differences in this experience, it is possible to determine the essential interventions and care activities that contribute to the highest levels of functional independence up to the end of life.

Further research is needed to

- Establish norms and indications for the application of rehabilitation in palliative care
- Determine cost-effectiveness of rehabilitation interventions
- Determine optimal time frames for providing rehabilitation services after the onset of disease
- Define variables having the greatest impact on patient outcomes

Conclusion

Rehabilitation nursing approaches have value in palliative care. Regardless of the disease trajectory, nurses can do something more to preserve function and independence and positively affect perceptions of quality of life, even at its end. Rehabilitation nurses facilitate holistic care of persons in their social and physical environments. They direct actions toward preventing secondary disability and enhancing both affected and unaffected body systems. They foster the use of adaptive strategies and techniques to optimize autonomy. The deliberate focus of rehabilitation nurses on function, independence, dignity, and the preservation of hope makes a fitting contribution to care at the end of life.

The Emergency Department

We were trained to rescue patients in the ED—I can’t just stand by and let someone die.
—Emergency physician and former residency director

Each year, there are 110 million visits to emergency departments (EDs) in the United States, and almost 1% or approximately 1 million of these visits result in death in the ED or hospital.¹ The emergency team in a busy ED typically perform or withholds attempts at resuscitation several times during an 8- to 12-hour shift.

Emergency physicians and nurses traditionally view themselves as foot soldiers in the trenches fighting against the enemy, dying and death. The criterion of success is whether the patient was admitted to the hospital or discharged to the community alive. Death is regarded as failure; it may be blamed on the disease or the patient’s response, but must not be blamed on a clinician’s lack of willingness to “do everything” to keep the ED patient alive. In this view, every ED case can be dichotomized into success or failure based on whether the patient left the ED with a pulse.

This traditional view of the ED misses the complexity and the reality of life and death. The reality is that each seriously ill person triaged in an ED presents in a crisis that has physical, emotional, social, and spiritual components. Each person who might die soon is at a particular point in his or her life cycle, and for the person and the family, death may be either unexpected or expected. For some of these patients, it would be unthinkable not to have all aggressive efforts to prolong life no matter its quality; for others, the ritualized set of resuscitative procedures before death is considered worse than death itself. In most EDs, there are clinicians who want to know the more complex and vulnerable person beneath the presenting disease label, who are willing to tailor treatment and disposition to the more important needs discovered.

This chapter on palliative care in the ED is designed to assist in recognizing and addressing the needs of irreversibly ill patients and their families. From this perspective, the key questions to be added to the basic ED assessment include the following: Is the patient/family aware of the presence of an incurable illness? What are their preferences for care, and how rapidly can we establish treatment goals? What can be done to

---

Key Points

- Each seriously ill person triaged in an emergency department (ED) presents in a crisis that has physical, emotional, social, and spiritual components.
- The growing number of patients presenting to the ED at the end of life means an increase in the proportion of patients for whom the default resuscitation approach is less applicable.
- Rapid identification of treatment goals with the terminally ill patient or surrogate prevents unwanted resuscitation and application of burdensome life-prolonging therapies.
- The most prevalent distressing symptoms that require immediate attention for the patient who is dying in the ED are pain and dyspnea.
- Unrestricted access of the family to the dying patient can be successfully implemented in the ED.
- An unexpected death in the ED requires a different approach to preparing the body for viewing that consists of minimizing delays and judicious draping.
relieve distressing symptoms? What can be done to ease the family’s distress and meet their needs?

The workload in the ED is such that, for most patients, the “greet, treat, and street” approach must necessarily prevail to prevent gridlock.2 But for the smaller number of patients who present with severe uncontrolled symptoms and organ failure that is not curable, recommendations made to lessen suffering and respect preferences for care can provide a rewarding sense of satisfaction for provider, patient, and family alike. There are a growing number of elderly persons in this country, and care teams are likely to face an increased incidence of terminally ill patients presenting to the ED who can be guided into the positive outcomes that palliative care can provide.

Recognizing Poor Prognoses

Experienced emergency nurses and physicians are able to recognize the gravely and terminally ill, who arrive with severe distressing symptoms, altered mental status, or imminent death. Examples are an 80-year-old with advanced dementia, decubiti, severe cachexia, and aspiration pneumonia; a 60-year-old with marked cachexia, dyspnea, metastatic non-small-cell lung cancer who has received surgery, radiation, and two courses of chemotherapy; a 50-year-old man with cardiac arrest, in pulseless electromechanical dissociation despite 20 minutes of three rounds of resuscitative therapy; the 60-year-old with severe diabetes and poorly controlled hypertension who has declined dialysis and is now in pulmonary edema with distressing dyspnea.

To help clarify thinking about patients who die, researchers have conceptualized them by placing them on one of five “dying trajectories”: (1) terminal illness, such as cancer; (2) sudden death, if younger than 60 years of age and previously healthy; (3) organ failure, such as congestive heart failure (CHF) and chronic obstructive pulmonary disease (COPD); (4) frailty, such as with dementia, bed bound, or with multiple recurrent hospitalizations; and (5) other. Data from Medicare decedents shows that 47% were considered to have died of frailty, 22% were on a cancer-like trajectory, 16% had organ failure, 7% had sudden death, and 8% were in the “other” category.3

Within each trajectory, death can be considered expected or unexpected by the provider or patient/family. If death is expected or known by the provider only, this is termed closed awareness; if known by provider and patient, it is called open awareness. Other possibilities are that neither the provider nor the patient is aware that the patient is dying (no awareness), or that the patient is aware but the provider is not, which can be termed “hidden awareness.”4 Assessment here has great implications, because the type of awareness of death (open versus closed versus no) often determines the ability of the provider to render optimal care.

Each trajectory has implications for a palliative approach to the patient. Sometimes such discussions take place in the ED, as they should if the ED clinicians recognize that the reflex curative/restorative ED procedure is in fact the “wrong” thing for the patient and family. More commonly, such decisions are “turfed” to the admitting team by default, although prudence would dictate that ED providers not hand off such discussions on nights or weekends, when the patient might die before others have had a chance to establish or review goals of care.

Patients with terminal illness who present with advanced disease and distressing symptoms should be assessed for their awareness of their prognosis. One approach is to ask the patient, “Tell me what you understand about your cancer.” Patients (or surrogates) with open awareness are good candidates to begin a palliative care approach in the ED, rather than resuscitation and admission to the intensive care unit (ICU). Palliative-directed intervention in the ED can help avoid the worst-case scenario: uncomfortable interventions in unrecognized terminal illness that result in a moribund patient who is unprepared for death and unable to make choices to forgo further non-beneficial interventions.

Patients who die suddenly present a number of challenges to ED clinicians. In general terms, they often leave behind loving family members who are not yet aware of their death. Patients who die unexpectedly of acute renal, respiratory, or heart failure are ideal candidates for the default ED approach and are amenable to all aggressive resuscitative efforts—unless there is an advance directive (AD) to withhold them. When death occurs in the ED after an attempt at resuscitation, the surviving families are ill-equipped to cope with the news and require intensive interventions directed at bereavement care. Studies have revealed that families want to be informed of the death in a compassionate and unhurried manner; to be reassured that the patient’s belongings will be properly handled; to be told what to do next (e.g., how to contact a funeral home); and to have the opportunity for follow-up with the hospital to answer unresolved questions.5–7 Development and implementation of ED-focused bereavement guidelines enhance the quality of care provided to the family after an unexpected loss.8–10 Patients with organ failure, notably those with CHF or COPD, are usually resuscitated or pronounced dead in the ED. Because the chance of pulling a patient through one more episode is relatively high, this course of action, conforming to the default ED approach, is often the road of least resistance and the most appropriate course. Inquiring about treatment preferences for resuscitative therapy is important if the patient is still alert or the family is available. Patients who arrive in extremis with clear expressions of their wishes, such as documented and confirmed forgoing of resuscitation, and hospice patients seeking comfort care that outstrips the home’s resources should continue to have their preferences honored by the ED team.

Patients dying on the frailty trajectory should have had ample time for their or their surrogate’s preferences to be established before the ED visit. As with patients with organ failure, they should have these preferences assessed and their awareness of dying probed. Admission for a palliative care approach rather than ICU admission could be considered.
The fact that growing numbers of patients are presenting to the ED at the end of life means an increase in the proportion of patients for whom the “default” ED approach is less applicable. This calls for a growing sensitivity of ED clinicians for greater skills in palliative care. ED staff must become comfortable with the decisions that patients or their surrogates make regarding forgoing resuscitative interventions and accepting natural death. ED staff are highly trained to rescue and, as with other specialty areas in the hospital, can provide the requisite palliative care interventions to patients and their families who may be dying in the ED.

Establishing Treatment Goals

When the terminally ill patient presents to the ED, rapid identification of treatment goals with the patient or the surrogate of an incapable patient is indicated and may prevent unwanted resuscitation and the application of other potentially burdensome life-sustaining therapies. Likewise, if palliative care treatment goals are established rapidly after an attempt at resuscitation, the patient and family can be afforded a quick transition from resuscitation to comfort by a skilled, compassionate ED intervention to withdraw unwanted life supports. Establishment of palliative care treatment goals in the ED can be inhibited by lack of prognostic information, the lack of any prior relationship with the patient or surrogate, a need for rapid action, and the fear of liability if life is not extended. Hopefully, clinicians in EDs will begin to see themselves as ideally positioned to identify and treat palliative care emergencies—such as pain crises—and adopt the goals of prevention of suffering and enabling of a “good death.” This development will expand the ED concept of success.

Most physicians (78%) responding to a survey study about cardiopulmonary resuscitation (CPR) indicated that they would honor legal ADs about resuscitation. However, despite more than a decade of experience with the Patient Self-Determination Act, there continues to be a paucity of persons who have completed an AD. In the general U.S. population only 15% of Americans have an AD, but among frail, elderly nursing home residents the prevalence of AD completion increases to 45% to 60%. Even if the AD accompanies the patient to the ED, it may have limited usefulness in guiding emergency management. One study found that, although 44% of nursing home residents seen in the ED had ADs, the ADs frequently addressed only CPR and did not address other life-supporting strategies (e.g., intubation) with the same frequency. Yet, even a limited AD provides the ED clinician with a starting point for a conversation about treatment preferences. The ED clinician can open the discussion with a request for clarification of the preferences expressed in the directive, and the conversation about contemporaneous diagnosis and treatment recommendations and preferences will flow. After ascertaining the patient’s or surrogate’s understanding about the illness, the clinician might ask, “I see you already have wishes about CPR; will you tell me more about your preferences for treatment?”

In the absence of an AD, or if the AD is ambiguous, the ED staff are obliged to engage in a decision-making process at the earliest opportunity after identifying or inferring the patient’s terminal prognosis. This conversation may occur before or after an attempt at resuscitation. A discussion with the patient who has retained decision-making capacity about diagnosis, prognosis, and relevant treatment options is a challenging process in the ED, because the patient may have no prior relationship with the ED staff and may be lacking bonds of trust and rapport. Furthermore, this type of clinician–patient conversation is ideally held in privacy and quiet, and the ED environment is not always a conducive setting. A creative approach to finding a quiet room or screening an area around the patient is needed.

Cognitive impairment is highly prevalent in terminally ill patients, particularly those whose death is imminent, and it may preclude them from having the capacity to make decisions about treatment. Reliance on a valid surrogate decision-maker, usually a family member or close friend, becomes necessary. Surrogates appointed by the patient through an AD have pre-eminence in decision-making. In the absence of a patient-appointed proxy, many states have enacted surrogacy statutes, often relying on a next-of-kin hierarchy, to direct clinicians. Clinicians need to know the provisions of their own state when seeking a surrogate decision about treatment. Table 46–1 details the core components of a discussion about end-of-life treatment options.

Case Study

HR, an 88-Year-Old Woman with Dementia

HR is an 88-year-old woman brought to the ED from her nursing home. She is in the terminal stage of dementia by physical examination and report from the nursing home, yet treatment goals have never been established with her only surviving family member, a niece. HR is curled into a fetal position and has stage III and IV sacral, trochanter, and heel decubiti. She is febrile, she has leukocytosis, and her chest radiograph is consistent with aspiration pneumonia. Her respiratory pattern and blood gas analysis predict imminent respiratory failure. The ED staff are in consensus that this patient would benefit from a palliative care approach rather than intubation and admission to the ICU.

The ED social worker calls the patient’s niece and asks her to come to the hospital as soon as possible. On her arrival, an ED physician, nurse, and the social worker sit with the niece, discuss the patient’s diagnoses and prognosis, and make a recommendation about comfort care. The niece agrees, thanks the team, and reports that no one has ever raised this option with her in the past. She believes that her aunt has “suffered enough” and should “pass naturally and peacefully.” The hospital’s palliative care service is consulted by the ED for admission, instead of the ICU.
Symptom Management: Pain and Dyspnea

The most prevalent symptoms that produce distress in the dying patient and require immediate attention are pain and dyspnea.\textsuperscript{31–34} The nursing process (i.e., assessment, planning, intervention, and evaluation) guides effective symptom management in the ED.

The gold standard for pain assessment is the patient’s self-report. When the patient is able to self-report, his or her appraisal of pain intensity, location, quality, and possible causes should be sought. A documented trend using a numeric rating or visual analog scale is standard and permits continuous assessment and reevaluation over time and across caregivers. Pain occurs as result of trauma, somatic disorders, and common ED procedures.\textsuperscript{25,26}

Critically ill patients and those with cognitive impairments may not be able to provide a self-report in such cases, a combination of measures is used to validate the assessment. Behaviors such as facial grimacing, restlessness, moaning, muscle tension, tachycardia, tachypnea, and diaphoresis may be cues to unrelieved pain.\textsuperscript{27–30}

Analgesics are the standard agents for managing pain in the terminally ill patient. Nonsteroidal antiinflammatory drugs have a limited role for treatment of mild to moderate pain and bone pain, and conservative use is recommended in the geriatric patient. Opioids, with the exception of meperidine, are the drugs of choice for moderate to severe pain, and antidepressants or anticonvulsants are used for neuropathic pain.\textsuperscript{31,32}

The route is chosen according to patient characteristics and goals of analgesia, including the desired rapidity of response. Intravenous or subcutaneous administration affords the most rapid onset of action. Oral, sublingual, or buccal administration causes the least patient burden when there is an intact oral cavity. Transdermal medication is useful for long-acting, chronic analgesia; it should not be used as the first-line strategy, because of the long delay in onset of action, and or if the therapeutic dose has not been determined, as may be the case with an ED patient. The intramuscular route is discouraged because of poor absorption and patient discomfort.\textsuperscript{31,32}

Analgesics are titrated according to the patient’s responses; therefore, frequent reassessment to evaluate effectiveness is indicated. Although an individual patient may experience toxicity, there are no dose ceilings when using opioids, and titration to therapeutic effect may require high doses in patients with opioid tolerance or severe pain. Equianalgesia tables and consultation with pain specialists may be used to guide appropriate dosing.\textsuperscript{31,32}

Like pain, dyspnea and any associated respiratory distress must be assessed frequently in high-risk patients, because many pulmonary, cardiac, and neuromuscular terminal illnesses produce breathing distress. The gold standard for this subjective experience is the patient’s self-report, using either a numeric or a visual analog scale. Behavioral cues are useful if the patient is unable to self-report and include tachypnea, tachycardia, accessory muscle use, a paradoxical breathing pattern, restlessness, nasal flaring, and a fearful facial expression.\textsuperscript{35}

Treatment of dyspnea or respiratory distress can be organized into three categories: prevention, treatment of the underlying cause, and palliation of symptom distress. Prevention of dyspnea in the dying ED patient warrants maximizing treatments that have proved beneficial to the patient, including enhancing ventilator synchrony if the patient is going to remain ventilated, avoiding volume overload, and continuing oxygen and nebulized bronchodilators. Measures to correct metabolic acidosis may also be useful to decrease the work of breathing and thereby decrease respiratory distress.

Treating underlying causes of dyspnea may be useful, particularly if the benefit of the treatment is not in disproportion

to the burden. If death is not imminent, the patient may benefit from antibiotics, corticosteroids, paracentesis, pleurodesis, or bronchoscopy.

A number of strategies have demonstrated effectiveness for palliation of terminal dyspnea, including optimal positioning, oxygen, and sitting in front of a fan. Upright positioning that affords the patient an optimal lung capacity is useful, especially for patients with COPD.38,39 Oxygen has been shown to be more effective than air in hypoxemic cancer patients36,37 and in patients with advanced COPD.38 However, other investigators reported no difference in cancer patients' respiratory comfort in response to oxygen compared with air,39 and increased ambient air flow, fans, and cold air have also been found to be therapeutic.40–43 Oxygen can be more burdensome than beneficial in the patient who is near death, particularly if a face mask is employed, because the mask produces a feeling of suffocation. The individual patient's report or behavior in response to oxygen determines its usefulness. The comatose patient does not require oxygen while dying.

Opioids are the mainstay of pharmacological management of terminal dyspnea, and their effectiveness has been demonstrated in clinical trials. A metaanalysis of 18 double-blind, randomized, placebo-controlled trials of opioids in the treatment of dyspnea from any cause revealed a statistically positive effect on the sensation of breathlessness (P = 0.0008). Metaregression indicated a greater effect in studies using oral or parenteral opioids than in studies using nebulized opioids. In subgroup analysis, the COPD studies had essentially the same results as the cancer studies.44 In the ED, parenteral access is almost universal, obviating the need for other routes of administration except in special or unusual circumstances. Doses for treating dyspnea are patient specific, and, as with opioid use in the management of pain, no ceiling should be placed on dosage. The dose should be rapidly titrated until the patient reports or displays respiratory comfort. Frequent bedside evaluation to assess the efficacy of the medication is essential.

Fear and anxiety may be components of the respiratory distress experienced by the dying ED patient. The addition of a benzodiazepine to the opioid regimen has demonstrated success in patients with cancer45 and with advanced COPD.46 As with opioids, these agents should be titrated to effect. Care of the attendant family to reduce their fear, anxiety, and grief warrants as much effort as that directed to the patient’s needs.

Family Presence

Studies have consistently demonstrated that families want to be close to their terminally ill loved ones.47,48 Family access promotes cohesion, affords the opportunity for closure, and may soothe the patient. Unrestricted access of the family to the dying patient is a standard of care in hospitals and nursing homes.49 The family of the patient who is dying in the ED should be afforded this same benefit. There is growing evidence and support for the successful implementation of families at the side of loved ones during resuscitation and invasive procedures in the ED.50–53 It follows that if families and patients can be accommodated with open access to one another in the ED during procedures, then unrestricted visiting for the dying patient and grieving family is possible.

Ideally, the patient and family should be separated from the hurried milieu of the ED while dying or waiting for a hospital bed, yet still visible and accessible for close monitoring and care. Movement to a quieter area in the ED, such as the observation care unit or an isolation room, may serve this purpose, particularly if there is space for a few chairs and the attendant family. Limiting visitors to only two at a time has no rationale if the patient is dying and there is a large, loving family.

Death Notification and Requests for Organ/Tissue Donation

Delivery of adverse diagnoses and death notification entails all of the communicative skills of the ED staff. A framework for communicating bad news is helpful. There are four temporally ordered segments in the approach to breaking bad news: the preparation, the content, the survivor’s response, and the close.54

Key elements of the preparation phase include a private setting, with determination of what the family already knows about the illness or accident. Important elements of the content phase include including a “warning shot.” For example, the physician might say, “There has been a factory accident, and I am sorry to say that I have bad news.” The news should then be stated clearly: “Your husband died in the accident.” Drawn-out deliveries may be more comfortable for the staff, but they are not helpful to the anxious family member.55

In order to cast death notification in an easily learned format, similar to the way other procedures are taught, a procedural competency model has been developed.56 The steps are summarized in Table 46–2.

Deaths that are out of cycle (e.g., death at a young age), out of context (e.g., death was not expected because oncologist overestimated length of life remaining), or sudden are the hardest for families to bear. Ideally, contact information for bereavement counselors or for support groups in the community should be given to the family.

Federal law (Public Law 99–5–9; Section 9318) and Medicare regulations mandate that hospitals give surviving family members the chance to authorize donation of their family member’s organs and tissues. Most families are receptive to requests for donation, and many take consolation in helping others despite their own tragic loss. Studies show that it is essential to approach relatives for this purpose only after death notification is completed, allowing a temporal separation between death notification and the request for organs. Also, a higher response rate is obtained if the requesting personnel have received specific training for this purpose.57,58
The nurse recognized the family’s need to see the body as quickly as possible. She enlisted a nurse’s aide to rapidly reduce the amount of debris on and around the stretcher. She draped the body to cover the worst injuries, including the

</table>

Give advance warning of bad news.

• “I’m afraid I have bad news.”

Deliver news of death clearly.

• Use direct terms such as “dead” or “died.”

• Use no medical jargon.

• Use language that is clear and easily understood.

Tolerate survivor’s reaction.

Explain medical attempts to “save” patient.

Offer viewing of deceased.

Offer to be available to survivor.

Conclude appropriately.

• Offer condolences and leave.

---

**Care of the Body**

It is commonly accepted that long-term outcomes are better for those who are able to see the deceased body of a loved one. Viewing the body helps those who are grieving acknowledge and begin to come to terms with the death.\(^{46}\) If the death is expected, the body should be bathed and laid out neatly on the stretcher with the eyes closed, and the preparation should be completed before the family arrives. Families who are present at the time of death may want to participate in body preparation. In some cultures, rituals at the time of death require family involvement and should be accommodated within reason in the ED. For example, in some Moslem traditions the body is turned to face east, and persons of the same gender and religion as the deceased perform the postmortem care. Some families may want private time with the body of the deceased, but others may want a supportive person from the hospital staff, such as a nurse, aide, or chaplain, to remain in attendance.\(^{51}\)

If the death is unexpected, such as from an accident or sudden illness, the family who are arriving at the ED need a different approach to viewing the body. After learning of the death, the family may demonstrate an urgency to see the body, and delays for cleaning and laying out may produce more distress; likewise, not seeing the body because of disfigurement or mutilation causes distress to the bereaved.\(^{50}\) Seeing the deceased and the evidence of the injury or accident, along with the accoutrements of the attempts at resuscitation, gives a subliminal message to the family that the ED staff did all they could.

The ED nurse should allow the family access to the deceased at the earliest possible opportunity and should use judicious draping to cover the most severe disfigurements.

---

**Case Study**

**HP, a Victim of a Motorcycle Accident**

While riding his motorcycle, HP was hit by a truck and dragged. He sustained a closed head injury, a severe scalp laceration, comminuted fractures of both femurs and of the left humerus, rib fractures bilaterally, and a ruptured spleen. He died in the ED during trauma resuscitation.

The frantic family arrived at the hospital shortly after death was pronounced and screamed to see the patient. The resuscitation room looked like a tornado had touched down, with empty supply wrappers, intravenous fluid bags, and soiled dressings on the counters and floor. The deceased was bloody, with his torn clothing partially removed or cut off, and bone was protruding from his left arm and both legs. He had bilateral chest tubes, a Foley catheter, three large-bore Angiocaths, and an endotracheal tube that had to remain in place for the medical examiner.

The nurse recognized the family’s need to see the body as quickly as possible. She enlisted a nurse’s aide to rapidly reduce the amount of debris on and around the stretcher. She draped the body to cover the worst injuries, including the
exposed bones, and washed the deceased’s face and hands. A hand towel covered the scalp wound without covering the face. Within five minutes the nurse had prepared the body and room for the family.

The nurse escorted the weeping family to see the body and remained unbosingly nearby in case anyone fainted. She also answered questions about the injuries and the magnitude of the efforts to resuscitate. Later, after the family was more composed, the nurse explained the procedures for referral to the county medical examiner and the need to identify a funeral home. She also gave the family the business card of a trauma counselor who specialized in bereavement counseling. The nurse found a quiet, private place for the family to wait until they reached an emotional calm that would allow them to drive home safely.

The use of cadavers to practice procedures such as endotracheal intubation in the ED has been commonplace as an integral part of resident training.62 Current ethical norms do not permit this practice without contemporaneous consent from the surviving family or evidence from a patient’s AD that this would be acceptable. Consent is standard elsewhere in health care, and respect for the newly dead and for the survivors warrants this same standard.63 Recent legal cases have held that families have property rights to the bodies of their loved ones, and the use of cadavers without consent poses a liability risk.64 Studies show that most patients or families are willing to have procedures performed after death if permission is obtained in advance.65,66 An empathetic expression of condolences, followed by a sensitive request to permit procedures, may yield the teaching-learning opportunity while demonstrating respect for the deceased and their family.

Summary

Dying care in the ED can be complicated by the milieu and by the usual “resuscitative” expectations of this environment. A default view of ED success is whether the patient left the ED with a pulse. The fact that a growing number of patients are presenting to the ED at the end of life demands palliative care competency by ED staff. In most EDs, there are clinicians who are willing to guide terminally ill patients or their surrogates toward a palliative care approach, in which success is redefined as preventing suffering and enabling a good death.

The paucity of patients with written ADs or advance planning for the terminal illness necessitates rapid establishment of treatment goals with the dying patient or surrogate in the ED. This is accomplished through compassionate communication about diagnosis and prognosis and recommendations for a palliative care treatment focus.

An abundance of evidence about managing pain and dyspnea is available to guide the ED staff in reducing symptom distress. Likewise, optimal caring for the grieving family has been informed by research and includes effective communication about prognosis or death notification and timely access to the patient before or after death.

Personal and professional satisfaction with comprehensive dying care in the ED can be achieved by ED staff. Compassionate recommendations made to decrease suffering and ensure respect for the dying patient afford the survivors a positive experience, even in the face of loss.

The Role of Nursing in Caring for Patients Undergoing Surgery for Advanced Disease

At least I’ll have a chance of being cancer free. Well, at least somewhat cancer free before the next bombardment, since it’s obviously a virus that I just can’t fight off. My immune system has been so compromised that I just can’t fight the cancer off. . . . With the surgery, they told me I won’t be in remission again. I’ll be in transition.—A patient

---

**Key Points**

- Patients and their family caregivers facing surgery for advanced disease have complex physical and psychosocial problems.
- Patients and family members require support as they make decisions regarding the benefits and burdens of treatments for advanced disease.
- Palliative surgeries affect physical, psychological, social, and spiritual well-being as well as additional health system outcomes.

---

**Case Study**

**Rosa Hernandez, a 38-Year-Old Woman with Cancer of the Gallbladder**

Rosa Hernandez is a 38-year-old Hispanic woman who resided in Southern California for the past 8 years, having previously lived her entire life in Mexico. She is married to Juan, and they have four children ranging in age from 6 to 17 years. Three months ago, she began to experience numerous gastrointestinal symptoms including bloating, mild nausea, abdominal pains, and severe indigestion. After trying numerous over-the-counter medications and herbal treatments, she sought medical evaluation and was diagnosed with cholangiocarcinoma. She and her family were drawn to the University Cancer Center, in part because a cousin who had been diagnosed with acute leukemia several years previously had been very successfully treated at this center and cured of his leukemia. They came to the Cancer Center with great confidence that Rosa would also be cured of her disease. The surgeon explained the seriousness of her cancer in the gallbladder and the widespread metastases to the liver. When offered treatment choices, Rosa and Juan as well as their large extended family aggressively voiced their desire for all treatments possible and repeatedly expressed their confidence in the surgical team and staff to save her life.

The surgeon explained that the procedure planned, resection of the tumor and partial liver resection, was not curative but might offer some relief for her symptoms. Juan expressed that they had faith in God and the surgeon. The evening nurse caring for Rosa, Emily James, approached the patient late one evening to discuss the surgical consents for the procedure planned the following day. Rosa told Emily that she had no questions and would sign the consents because she was eager to get rid of the cancer in her body.
This case illustrates the numerous complexities of caring for patients with advanced disease for whom surgical treatment may be an option. The nurse is faced with caring for a patient with advanced cancer and a poor prognosis yet both the patient and family are expecting a “miracle.” There are many complex cultural and social factors affecting her decisions for care as well. The nurse is challenged to work with the patient, her family, the physician, and other interdisciplinary colleagues to provide the best information and support for this family, while also anticipating the many immediate postoperative needs as well as the longer-term symptom management and disease issues. This case is but one example of the incredibly complex and challenging needs of patients undergoing surgery for advanced disease.

Decision-Making in Palliative Surgery

Patients facing advanced disease are often in the position of making difficult choices with regard to treatments. Patients often face that critical juncture of determining when they should continue disease-focused treatments such as chemotherapy, radiation, or surgery and when it is time to stop such treatments. Even amid the recognition of advanced disease, patients often seek aggressive treatment with the hope of prolonging their survival, even if only for a matter of months, or of possibly enhancing their quality of life (QOL) through the relief of symptoms.1-3

Figure 47–1 is derived from research in the area of palliative surgery conducted at the City of Hope National Medical Center (COH).4 The model demonstrates that the process of making decisions about palliative surgery often involves influences from the patient, the family, and the health care team. Patients and families must weigh the potential benefit versus the harm of the surgery proposed, while the health care team considers factors such as the difficulty of the procedure, the duration of hospitalization, recovery time, chance of achieving the goal, anticipated durability of the intervention, and anticipated disease progression. It becomes evident in reviewing these factors that much of the decision-making involves great individual variation, so that it is difficult to estimate who might benefit most from more aggressive intervention. For example, the patient with a poor prognosis due to an extremely advanced gastrointestinal tumor, who subsequently lives twice the original duration anticipated, may well have been the patient who

![Figure 47-1. Clinical decision-making in palliative surgery. Source: Ferrell et al. (2003), reference 4.](image-url)
could have benefited from surgery to relieve obstruction for abdominal pressure causing severe nausea, vomiting, or bowel problems.

The process of making decisions involves a focus on goals of care, recognizing the values of the patient, acknowledging alternatives, and always weighing the risks versus benefits. As surgeries have become more advanced in technique, it is often possible to do very extensive surgery on an outpatient basis or with very short hospitalization time. This reduced “burden” makes it more likely that patients may opt for surgical procedures. Given the many symptoms or problems resulting from advanced disease, patients consider a variety of treatment choices, including surgery, chemotherapy, radiotherapy, or a combination of treatments.

The outcomes of this process of decision-making are depicted in Figure 47–1 as affecting all dimensions of QOL. Physical well-being and symptoms, as well as function, are almost always affected by treatment choices. Psychological well-being, including anxiety and depression as well as fears, is also influenced by treatment choices. Patients and families have often reflected that, although a particular treatment may have not prolonged survival, it gave them a tremendous sense of assurance that everything possible was being done to treat the illness. In the realm of social well-being, the choices of treatments have very significant impacts on the patient’s roles and relationships as well as the burden on caregivers.

Although invasive, “high-tech” treatments may often be thought of as adding to the caregiver burden, in advanced disease the failure to aggressively treat problems commonly results in heightened burden. For example, a patient who declines surgery relatively early in the course of an advanced gastrointestinal tumor may then experience much worse nausea, vomiting, diarrhea, and subsequent complications that could result in a more intense caregiver burden than would have been required after earlier surgery.

Finally, spiritual well-being is greatly influenced by decisions regarding palliative surgery, because patients rely upon their faith and religion in making treatment choices. One of the strongest themes throughout palliative care research at the COH has been the concept of hope. This concept is covered in greater detail in Chapter 26, but it certainly applies closely to the topic of palliative surgery. Patients may perceive that surgery, even if presented as only palliative in nature, is still potentially curative or life-prolonging, and therefore may opt for surgery with unfounded hope for a cure.

The model in Figure 47–1 illustrates how important it is for nurses to provide education, counseling, and support as patients and families wrestle with treatment choices. It is also not uncommon for patients and families to have different perspectives and conflicting opinions. For example, a patient with advanced disease may opt for no further invasive treatments and instead focus on measures of comfort. At the same time, family members may press for the patient to endure continued procedures for even the smallest possibility of prolonged survival.

Research in Palliative Surgery

There has been limited research in the field of palliative care and even far more limited focus on the area of palliative surgery. Recent studies have begun to document both the lack of research in the field and the limitations of existing research. Leaders in the field of palliative surgery have documented that few studies evaluating these procedures have included measures of patient QOL, symptom management, or psychosocial concerns.

Research in the area of palliative surgery was initiated at the COH in 2000, and since that time a series of studies has been conducted involving collaboration between the Department of Nursing Research and the Department of Surgery. Table 47–1 summarizes phases of this research thus far. The studies have included a review of surgical cases to determine the extent of palliative surgery use at a cancer center, which was followed by a prospective review of cases that led to research evaluating decision-making by patients and family members.

In order to broaden understanding of palliative surgery beyond one cancer center, phase III involved a survey of 419 surgeon members of the Society of Surgical Oncology. A very important finding of this research was the identification of ethical dilemmas faced by surgeons, such as providing patients with honest information without destroying hope and preserving patient choices.

These early studies have led to clinical investigations exploring symptom management and QOL outcomes, as well as longitudinal measures, in an effort to capture the effects of palliative surgery and its potential impact on symptoms and QOL. These studies have also provided an opportunity to incorporate qualitative methods for exploration of patient and family caregiver experiences.

Patient Perspectives

The research at COH has explored patient perspectives of surgery through in-depth individual interviews conducted pre-operatively and postoperatively, as well as assessment of symptoms and QOL. Table 47–2 includes some representative comments from patients’ perspectives of QOL after surgery. As this study demonstrated, patients may believe that surgery is their only option to avoid progression and eventual death from their disease. The presence of physical symptoms has been found to be a key motivator for seeking surgical intervention. Even those patients who recognize that surgery is not curative may aggressively seek surgical approaches to relieve distressing physical symptoms such as pain, gastrointestinal symptoms, bleeding, odors, and other problems. These studies also demonstrated that tremendous psychological stress and anxiety are induced by the need to make decisions about surgical options. Having surgery in advanced disease seems to be a stark reality given the extent of the disease. Also, it is not uncommon to find evidence during the surgery of far more advanced disease than was originally known.
Phase I
Surgical Palliation at a Cancer Center (Krouse et al. [2001], reference 25)

**Design:** Retrospective review of surgical cases \( n = 1915 \) during a 1-year period with a 1-year survival follow-up. This descriptive study began exploration of the extent of palliative surgery and identification of patient outcomes.

**Key Findings:** Palliative surgeries (PS) comprised \( 240 (12.5\%) \) of 1915 surgical procedures. There were 170 major and 70 minor procedures. Neurosurgical (46.0%), orthopedic (31.3%), and thoracic (21.5%) surgical procedures were frequently PS. The most common primary diagnoses were lung, colorectal, breast, and prostate cancers. Length of hospital stay was 12.4 days (range, 0–99 days). Mortality was 21.9% for surgical procedures classified as major and 10.0% for those classified as minor. The investigators concluded that in significant numbers of PS mortality was high; however, a significant number of patients had short hospital stays and low morbidity. PS should remain an important part of end-of-life care. Patients and their families must be aware of the high risks and understand the clear objectives of these procedures.

Phase II
Advancing the Evaluation of Palliative Surgery for Cancer Patients (Krouse et al. [2002], reference 20)

**Design:** Prospective review of PS \( n = 50 \). Pilot testing of interview guide for use with patients/family caregivers and surgeons to explore decision-making and goals.

**Key Findings:** Prospective design allowed expansion of outcomes to include quality of life (QOL) and exploration of the involvement of family caregivers.

Phase III
Indications and Use of Palliative Surgery—Results of Society of Surgical Oncology (SSO) Survey (McCahill, [2002a and 2002b], references 21 and 22)

**Design:** Mailed survey (110 items) of members of the SSO \( n = 419 \) responses). This phase was intended to provide a national perspective on the topic of PS and to expand knowledge of surgeons' decision-making.

**Key Findings:** Surgeons estimated 21% of their cancer surgeries as PS in nature; 43% of respondents believed PS was best defined based on preoperative intent, 27% based on postoperative factors, and 30% on patient prognosis. Only 43% considered estimated patient survival time an important factor in defining PS, and 22% considered 5-year survival rate important. Patient symptom relief and pain relief were identified as the two most important goals in PS, with increased survival the least important. On a scale of 1 (uncommon problem) to 7 (common problem), surgeons reported that the most common ethical dilemmas in PS were providing patients with honest information without destroying hope and preserving patient choice. On a scale of 1 (not a barrier) to 7 (severe barrier), surgeons rated the most severe barriers to optimum use of PS as limitations of managed care and referral to surgery by other specialists. The least severe barriers were surgeon avoidance of dying patients and surgery department reluctance to perform PS.

Phase IV
A Prospective Evaluation of Palliative Outcomes for Surgery of Advanced Malignancies (McCahill, [2003], reference 23)

**Design:** Prospective evaluation of patients undergoing PS \( n = 59 \) with longitudinal measures for 1 year. Outcomes were expanded to provide more detailed evaluation of symptom management and QOL. Qualitative evaluation included in-depth interviews of patients, family caregivers, and surgeons before and after surgery to further describe decisions and outcomes related to surgery.

(continued)
**Table 47-1**

**Description of Program of Research (continued)**

**Key Findings:** Preoperatively, surgeons identified 22 operations (37%) as PS, 37 (63%) as curative. Thirty-three patients (56%) were symptomatic preoperatively, and symptom resolution was documented in 79% surviving >30 d. Good to excellent palliation, defined as “more than 70% symptom-free non-hospitalized days relative to postoperative days of life,” was achieved in 53% of PS patients. Among patients with postoperative survival <6 mo, 63% had good to excellent palliation. The majority of symptomatic patients undergoing major surgery for advanced malignancies attained good to excellent symptom relief. The researchers concluded that outcome measurements other than survival are feasible and are likely to play an important role in defining surgery as an important component of multimodality palliative care.

**Phase V**

A Comparison of Resource Consumption in Curative and Palliative Surgery (Cullinane et al. [2003], reference 19)

**Design:** Prospective evaluations of all surgeries performed over a 3-month period \((n = 302)\) with 6-month follow-up. The investigators extended the outcomes of surgery to be evaluated based on Phases I–IV.

**Key Findings:** Over a 4-month period, the outcome and service needs of 302 consecutive patients with malignancy undergoing surgeon-defined PS or curative surgery were evaluated. Previous treatment history, comorbidities, symptoms, procedures, outcome, and use of supportive services were collected. Patients were monitored for 6 months after the surgical procedures performed for cure (breast or prostate cancer) or for palliation (breast, lung, and bone/soft tissue tumors). There were 3 (1%) curative and 4 (6%) palliative deaths during the surgical admission. Mean hospital stay was 5.3 days (range, 0–58 days) for curative surgery patients and 1.9 day (range, 0–14 days) for PS patients. After discharge, a total of 4690 encounters with the cancer center occurred, including 1676 encounters with surgery, 1595 encounters with medical oncology, 1006 encounters with radiation oncology, 226 visits to medical specialists, and 187 visits with supportive services. Mean number of encounters for curative and PS patients were 15 and 17, respectively, \((P = 0.41)\). Curative patients were more likely to have visits with therapeutic intent, including chemotherapy \((P = 0.01)\) and radiation \((P = 0.003)\). Readmission occurred in 82 (34%) of curative and 28 (48%) PS patients during the 6-month period \((P = 0.04)\). PS patients were more likely to be admitted for symptom management \((P < 0.0001)\), whereas curative surgery patients were more likely to be admitted for repeat procedures \((P = 0.006)\).

**Phase VI**

Concerns of Family Caregivers of Cancer patients Facing Surgery for Advanced Malignancies (Borneman et al. [2003], reference 1)

**Design:** Family caregivers were assessed before planned PS and at 2 weeks and 6 weeks after surgery. Quantitative assessment of caregiver QOL occurred at each time point. A subset of nine caregivers also participated in a structured interview before surgery and at 2 weeks after surgery.

**Key Findings:** The study findings indicate important family caregiver QOL concerns and needs for support at the time surrounding surgery for advanced disease. Psychological issues were most pronounced, and concerns of family caregivers of patients facing surgery for advanced malignancies. Family caregivers \((n = 45)\) were assessed before planned palliative surgery and at 2 weeks and 6 weeks after surgery. Quantitative assessment of family caregivers voiced concerns about surgical risks and care after surgery and experienced decision-making were evaluated. Findings of the study indicated that family caregivers have important QOL concerns and needs for support before and after surgery for advanced disease. Psychological issues were most pronounced, and recognition of the patient’s declining status. The investigators concluded that surgery is an important component of palliative care and is an area requiring further research and clinical attention.
common concerns included uncertainty, fears regarding the future, and loss.

Family caregivers had concerns about surgical risks and patient care needs after surgery and voiced recognition of the declining status of patients. The needs of family caregivers are multiple and complex, requiring ongoing assessment to provide interventions that help them cope and ultimately improve their QOL. This important topic requires further research and clinical attention.

Table 47–3 includes examples of family caregivers' perspectives provided both preoperatively and postoperatively. Families articulated their concerns about the surgery and its risks and in fact were more concerned than patients about potential negative consequences of surgery.5 Family members often discussed the benefits of surgery, with a strong sense from both patients and family caregivers that surgery is always a good option because “to take it out” must increase one’s chance for survival. For family members, however, the postoperative period was most often one of incredible stress as they faced the reality that the patient’s prognosis was not likely to have changed and
that surgery may in fact have revealed more evidence of advanced disease. For many patients, the surgical experience became a “roller coaster,” in which they grasped for hope for a cure from surgery, even if intended as palliative, but the hope was balanced by recognition of the patient’s decline in status.

**Nursing Care of Patients Undergoing Palliative Surgery**

The care of patients undergoing palliative surgery is often focused more on the medical aspects, yet nursing care is essential throughout all phases of preoperative, intraoperative, immediate postoperative, and postoperative recovery and discharge. This is a critical time, with numerous transitions between care settings, and nurses can play a vital role in ensuring continuity across settings such as the operating room, intensive care unit (ICU), postoperative surgical unit, and home care. A prime example is the role of nursing in ensuring pain management by assessing a patient’s chronic pain problem at the time of admission to plan adequate analgesia as the patient is admitted for surgery. The nurse then works collaboratively with the physician and the pharmacist to plan the analgesic orders for the transition from the oral analgesics used preoperatively to an appropriate regimen after surgery. Additional monitoring is needed, because the patient’s pain may escalate after major surgery, and also to ensure the appropriate changes as the patient goes from chronic oral medications at home to parental administration in the postoperative period and in the ICU. Maintaining adequate analgesia after discharge from the ICU, onto the postoperative unit and then to home care, is essential for the patient’s timely discharge to home and remains a requirement during recovery. This simple example of just one aspect of care, pain management, illustrates the vital role of nursing during this very acute phase of treatment.

Patients with advanced disease often undergo surgery with the goal of palliation to achieve a longer survival, even when cure is not a realistic goal. The following case illustrates this point:

**CASE STUDY**

*Carl Freedman, a 52-Year-Old Man with Colon Cancer*

Carl Freedman is a 52-year-old African American man with stage IV colorectal cancer who has previously undergone surgery for bowel resection followed by chemotherapy. After a prolonged postoperative course and extensive recovery phase, Mr. Freedman was able to resume his work as a maintenance man in a local school. He was admitted to the hospital 2 days ago with signs of bowel obstruction accompanied by symptoms of nausea, vomiting, abdominal pain, and dehydration. On evaluation, Mr. Freedman was found to have a recurrence of the bowel cancer and adhesions with partial obstruction in the bowel. The surgical team meets with Mr. Freedman and his wife to explain the significance of the recurrent cancer and the bowel obstruction and to offer some alternatives for treatment. Because of the location of the obstruction and extent of disease, the surgeon presents nonsurgical approaches, including the use of octreotide and bowel rest, as well as the option of surgery to remove part of the tumor and adhesions. But the surgeon is honest in discussing with Mr. Freedman and his wife the finding that the cancer has metastasized to the liver, that the procedure would not be curative, and, indeed, that his prognosis has now worsened. Mr. Freedman and his wife have a strong faith and believe that “God will guide you, Dr. Barnes, and His hands will help you get the entire tumor.” They also say, however, that their most important goal is to see Mr. Freedman live until the graduation of his son from college in 4 months. They explain that this is a particularly significant event, given that their son will be the first in the family to have completed college.

This case illustrates the role of palliative surgery and the benefit of extending patient survival to achieve life goals even if a cure is not possible. Nurses would play a vital role in Mr. Freedman’s care, including aggressive management of his existing symptoms and additional psychosocial support required at this critical time in his illness, as he and his family confront the reality of his worsening disease. Continued attention would also be needed after surgery to monitor Mr. Freedman’s progress. For example, if his disease progressed more rapidly or if he developed postoperative complications that could lead to shorter survival, it might be necessary to work with the family to realize what choices they could make if indeed he did not live to see the graduation. Supporting Mr. Freedman’s faith and the spiritual crisis that might develop if he believed that God had failed him would be essential. This case also illustrates the vital role of nurses in monitoring patients after surgery to assist with transitions to home care/hospice or palliative care programs.

**The Goal of Symptom Relief**

The following case study illustrates the goal of symptom relief in palliative surgery.

**CASE STUDY**

*Bonnie Crate, an 83-Year-Old Woman with Sarcoma*

Bonnie Crate is an 83-year-old Native American woman who was diagnosed with sarcoma approximately 1 year ago. She had experienced severe pain in her shoulder and arm but did not seek medical care; rather, she relied on traditional Native American healers and treatments, believing that her pain was “old age” and arthritis. When she developed severe neuropathy
in her hand and was no longer able to cook or care for her grandchildren, she sought medical assistance and was informed of her diagnosis. She opted for supportive care only and initially was not interested in the possibility of surgery or chemotherapy; however, she did want aggressive symptom management with a goal of reducing her pain and maintaining her function “to be a grandmother as long as possible.” Bonnie has now moved from her rural tribal community into the home of her daughter in the metropolitan area. Bonnie was seen by the pain and supportive care service at the hospital. However, after numerous attempts at multiple analgesics, treatment of neuropathic pain, unsuccessful attempts at both oral and parenteral analgesics, and a brief trial of epidural analgesia and nerve blocks, the team was unsuccessful in achieving pain relief without excessive side effects.

Bonnie is evaluated by surgery staff, and an option is presented that would involve amputation of her arm for the relief of the pain. On initial presentation of the option her children become extremely agitated saying “Are you crazy?! Why would you take off the arm of an 83-year-old woman?” However, Bonnie tells her children that she will do anything to get some relief from the pain, and with only one arm she could still hold a grandchild. The nurse practitioner in the surgical clinic meets with the patient and family, along with the surgeon, to describe the procedure and the expected postoperative course.

Bonnie undergoes surgery and does extremely well in the postoperative period. She is discharged 1 week later with plans for follow-up evaluation by occupational therapy and return to the pain and symptom clinic for continued monitoring of her symptoms.

This case illustrates the role of surgery in relieving severe symptoms that have been unresponsive to less aggressive means. It also illustrates the importance of evaluating the patient’s goals of care and circumstances and that quite often surgical intervention, although considered to be invasive or aggressive, may be the best option even in the face of advanced disease.

**Psychosocial Issues Affecting Palliative Surgery**

Patients facing advanced disease and critical associated decisions related to treatment options also present with complex psychosocial and spiritual needs. The following case illustrates complex issues in patients who are torn between the desire to survive and weariness and readiness for life’s end.

**CASE STUDY**

**Alexandra Nopteski, a 63-Year-Old Woman with Colon Cancer**

Alexandra Nopteski is a 63-year-old Russian immigrant residing in Southern California. She and her husband immigrated to the United States approximately 20 years ago and began a janitorial service cleaning office buildings. They are very proud parents of three children, all of whom have completed college. The family has been very prosperous and approximately 5 years ago became U.S. citizens. Three years ago, Alexandra’s husband died suddenly from a myocardial infarction. She and the children were devastated, and she has been moderately depressed since that time. Approximately 1 year ago, Alexandra developed cancer of the colon and underwent surgery and radiation therapy, with numerous postoperative complications including a chronic problem with abscess formation and fistulas. She has had a fairly sharp decline in status over the last 6 months.

Alexandra has made her wishes very clear: she does not want life-sustaining treatment and does not want further chemotherapy or radiation therapy. She has felt very sad about the burden that she believes is imposed on her children and wants for them to be able “get on with their lives in America and not be burdened by me.” Over the past month, Alexandra has developed heavy rectal drainage which is resulting in constant soiling of her clothing and a very offensive odor. The oncology surgeon has recommended a surgical procedure to remove some of the abscess and fistula areas to eliminate or reduce this problem. Alexandra agrees to the surgery but is somewhat hesitant. She mentions to the nursing assistant that she had hoped that it wouldn’t come to this, stating, “I think I’m dying from the inside out.” The surgical resident comes to obtain her consent for the surgical procedure. She becomes extremely angry and hostile when the resident informs her that her “do-not-resuscitate” order will have to be rescinded for her to have surgery, because it is the hospital’s policy that all patients entering surgery are at full code status. Alexandra tells the resident that she and her deceased husband will haunt him for the rest of his career if he should “rob her the opportunity to die” if God deems it should be so during surgery. The resident leaves very shaken, and the nurse comes to the bedside to talk with her. Alexandra is not to be consoled, saying she still wants the surgery, but she can’t imagine that the surgeons would want to resuscitate her if the need should arise during surgery. After she becomes much calmer, she admits to the nurse, “On the other hand, I wish that maybe my heart would stop during surgery so that it would be easier for everyone if I could die quickly rather than prolonging this agony.”

The case of Mrs. Nopteski illustrates the complexities of dealing with patients with advanced disease. Cultural, spiritual, and psychosocial issues are important influences. This case also illustrates the importance of nursing leadership in creating policies and procedures that support the goals of palliative care. Many institutions have eliminated their requirement for full code status on patients undergoing surgery and instead now honor the request to avoid resuscitation even if its need should occur during surgery. Mrs. Nopteski’s clinical signs of depression are also important to evaluate in considering her
overall plan of care. A patient’s wish for death should never be dismissed, and such information should be shared with the surgical staff. Instances such as this are also primary examples for incorporating psychiatry or psychology: evaluation of her depression is essential, and attention to her emotions would be needed before the surgery as well as in the follow-up period. Nurses play a critical role in attending to the communication around this issue and in acting as the patient’s advocate in all stages of care and across settings.

Summary

Palliative nursing care extends across all treatment modalities, and patients undergoing surgery require intensive support and care. Nurses play a critical role in patient and family communication, establishing goals of care and expert management of symptoms. There is a need for continued research to address this area of palliative care and for continued advancements of clinical nursing expertise to best serve these patients and families.24–26

Palliative Chemotherapy and Clinical Trials in Advanced Cancer: The Nurse’s Role

I wanted to give chemo another chance because I am never one to give up easily. This time around, it’s not the chemo that scares me; it’s what comes along with it—the side effects. I don’t want to die from the side effects.—A patient

Nurses have always been in the forefront of managing treatment-related symptoms. In an ever-changing and complex health care setting, optimal care requires a transdisciplinary approach. This approach is especially valued in an oncology setting, where patients frequently present with complex disease- and treatment-related symptoms. These often debilitating symptoms negatively affect the quality of life (QOL) of patients and their extended families. For patients with advanced cancer, treatment options are often limited. It is usually at this stage of the cancer continuum that discussion of palliative modalities of treatment occurs. These palliative modalities often include, but are not limited to, radiation, surgery, and chemotherapy. It is also during this stage of the continuum that physicians discuss the use of investigational therapeutic agents as an attempt to control the disease. However, it is not uncommon for patients and families to be faced with difficult decisions. Patients with advanced cancer are often caught between the dichotomy of continuing aggressive treatment and the focus on quality supportive and palliative care. The debate of treatment futility often comes into play at this stage of the cancer continuum, because patients and families are faced with a shorter life expectancy and all standard therapeutic regimens have failed to control the spread and proliferation of the tumor itself. Faced with these difficult decisions, patients and families become especially vulnerable and may experience heightened physical, psychological, social, and spiritual distress.

In advanced malignancies, the choice between palliative chemotherapy, clinical trial, or best supportive care may be difficult. This chapter describes the use of chemotherapy and cancer investigational agents as a palliative treatment for patients with advanced cancer. Emphasis is placed particularly on the role of palliative chemotherapy and the dichotomy between clinical trials of cancer investigational therapeutic agents and palliative care. Finally, an in-depth analysis of the role of nurses in supporting patients and families receiving palliative chemotherapy or investigational agents through clinical trials is discussed.
Definitions

Palliative chemotherapy, in its broadest sense, is the use of systemic antineoplastic agents to treat an incurable malignancy. In most medical literature, the efficacy of palliative chemotherapy is reported through data regarding tumor response rate, duration of response, and survival benefit. However, the purpose of these studies usually is not the investigation of these agents for palliation of symptoms, even though most subjects accrued into these clinical trials are deemed incurable. It is only in recent years that symptom palliation has become an important aspect in the design and evaluation of cancer clinical trials. The majority of the symptom palliation research incorporated into therapeutic clinical trials focuses on QOL as a prognostic factor for better patient outcomes. Other, more specific definitions used to describe palliative chemotherapy include the relief of cancer-induced symptoms. This refers to the use of antineoplastic agents with the expectation of prolonged survival and improved QOL, which includes the relief and prevention of adverse symptoms that are indicative of advanced malignancies.

Curative versus Palliative Chemotherapy

As a primary therapy, chemotherapy may be potentially beneficial in the prolongation of survival in the advanced stages of cancer. However, the majority of malignancies in adults are incurable with chemotherapy. Although the development of adjuvant chemotherapy has resulted in a decrease in recurrence rates, the data show that there is no significant difference in disease-free survival. Therefore, the majority of patients living with cancer will experience recurrence of disease, and it is this population that may also receive palliative chemotherapy.

When the disease has metastasized to other organ systems, the primary goal of using chemotherapy in advanced disease is to control the patient’s symptoms and maintain QOL. The rationale for palliating direct or indirect symptoms of cancer is multifaceted, but it is important for practitioners to remember that not all patients are suitable for palliative chemotherapy. Standard chemotherapy should not be offered to all patients with metastatic malignancies. A predicted toxicity of treatment should preclude any consideration for the use of palliative chemotherapy. The benefit-to-toxicity ratio of treatment should be seriously considered. Never should subtherapeutic doses of chemotherapy be given to maintain hope in a patient’s prognosis. Such a false sense of hope may prove to be even more distressing and may induce tremendous suffering for patients and families.

Several prognostic factors have been used in chemotherapeutic treatments of cancer to determine palliative treatment modality. One of the most important prognostic factors is performance status. A severely debilitated patient with a restricted performance status is more likely to sustain excessive chemotherapy toxicity. The site of metastasis outside the primary tumor can also be prognostic of patient response to symptoms related to treatment. These tumor-specific prognostic factors are crucial because they can assist nurses in defining an incurable disease.

The decision to treat or not to treat is based not only on clinical indicators but also on the patient’s perspective. Chemotherapy involves a commitment on the part of the patient and family to travel to the treating institution on a scheduled basis. Repeated hospitalizations, venipunctures, cannulations, investigations, and assessments over and beyond the actual administration of chemotherapy are inevitable routines of cancer treatment. These factors need to be addressed with patients and families in an effort to facilitate the decision-making process.

Quality of Life Concerns in Palliative Chemotherapy

The assessment of QOL has increasingly become a key measure in cancer clinical trials, in conjunction with other measures such as tumor response, disease-free survival, and overall survival. Some of the parameters commonly included in QOL measurement tools are factors that affect the quality of a patient’s physical, psychological, social, and spiritual well-being. QOL should be used clinically to weigh the benefit-to-toxicity ratio of palliative chemotherapy. Aside from assessing antitumor effects and the toxicity of chemotherapy, the overall positive or negative impact of the treatment on QOL must also be addressed. An ideal situation in which palliative chemotherapy might be beneficial is one in which the treatment does not alter survival duration but does positively affect QOL.

Very few prospective studies have investigated the QOL benefits of supportive care versus a combination of palliative chemotherapy plus supportive care for the management of advanced, incurable malignancies. The average prolongation of survival with chemotherapy compared with best supportive care has not been fully described in literature. An increasing number of studies have reported the potential palliative benefits of chemotherapy. Shanafelt and colleagues performed a systematic analysis of 25 randomized, controlled clinical trials comparing cytotoxic chemotherapy with best supportive care. Sixteen of the clinical trials involved patients with non-small-cell lung cancer. The results indicated that there is a modest relationship between response rate and both median and 1-year survival rate for non-small-cell lung cancer patients treated with cytotoxic chemotherapy.

A meta-analysis of randomized clinical trials of best supportive care versus chemotherapy for unresectable non-small-cell lung cancer was performed to allow for better determination of the actual statistical significance of the treatment effect. There was a survival benefit in the range of 6 to 10 weeks for those patients treated with palliative chemotherapy. However, this benefit was seen only in patients who had an adequate
performance status. Patients with Eastern Cooperative Oncology Group (ECOG) performance status of 3 or 4 had no benefit from chemotherapy. In summary, it appears that palliative chemotherapy is effective only for a select group of patients in the lung cancer population. A strong predictor of positive treatment benefit is related to the patient’s performance status.

In a study of patients with unresectable metastatic or locally advanced non-small-cell lung cancer, subjects were randomly assigned to receive either best supportive care or two different chemotherapy regimens (n = 150). Survival was 8 to 15 weeks longer for the chemotherapy + supportive care arm, but improved survival was observed only in patients who had a high ECOG performance status (0 or 1) and a weight loss of <5 kg. Moreover, about 40% of subjects were judged to have sustained severe, life-threatening, or lethal toxicities. Very few patients showed improvement in performance status or gained weight during chemotherapy treatment.

The QOL of family caregivers was addressed in a study to compare the impact of cancer caregiving in curative and palliative settings. Family caregivers of patients receiving palliative care had significantly lower QOL scores and lower overall physical health scores. There was no additional significant variability in caregiver QOL scores after adjustments for patient performance status and treatment status. These results suggest that patients’ poor performance status is a predictor of low QOL in the palliative care setting that also affects caregivers’ QOL. The data reinforce the importance of supporting families as well as the impact on their QOL and on the patient’s well-being when the treatment intent is palliative.

**When and How Long to Treat?**

Multiple factors need to direct the decision-making process when considering palliative chemotherapy for patients with advanced cancer. The goal at this juncture in the cancer continuum is to relieve or prevent tumor-induced symptoms, with the potential of prolonging survival. Patients who are symptomatic from malignancy, and those who are expected to be symptomatic soon, are typically considered for treatment initiation within a few days or weeks. This indication for palliative chemotherapy, although proven to be somewhat beneficial for effective palliation in oncologic emergencies, is appropriate for only selected patients. Local treatments with palliative radiation or surgery are also common treatment modalities in advanced malignancies.

A more difficult scenario of whether to delay or begin palliative chemotherapy occurs with patients who are asymptomatic from malignancy. In these circumstances, especially with tumor types that are less responsive to chemotherapy, the general consensus is that the benefit-to-toxicity ratio may be more heavily weighted toward the toxicity side. In such situations, treatment may be withheld and the patient closely monitored until symptomatic progression is evident.

**CASE STUDY**

**Mrs. G, a Patient with Pancreatic Cancer**

Mrs. G is a 72-year-old retired special education teacher who was diagnosed with pancreatic cancer 2 months ago. At the time of diagnosis, her disease had metastasized to her liver and lung. She has been fairly asymptomatic except for some dyspnea on exertion, which has caused her to cease her nightly walks around the block with her Chihuahua. She has been wheelchair bound since diagnosis due to her decreasing energy level. Mrs. G’s daughter, who lives nearby and visits frequently, and her husband, who last year suffered a severe case of pneumonia, have encouraged her to be aggressively treated. She was started on palliative chemotherapy with weekly gemcitabine. Within 2 weeks, her platelet count dropped, and her energy level significantly decreased to the point where she had trouble with activities of daily living. Her daughter temporarily moved in to assist her in daily tasks. Mrs. G continued on the treatment with dose reductions and schedule changes for another 4 weeks and was then referred to hospice. She passed away at home after 1 week of hospice referral, with her husband, daughter, and dog at her side.

In this case, a focus on watchful waiting or aggressive supportive care was indicated. In general, pancreatic cancer is not a very chemosensitive tumor. Mrs. G’s performance status was low; therefore, she could be anticipated to experience more difficulties with treatment side effects. The treatment schedule was also too intense given her performance status. As a result, Mrs. G suffered from a further decrease in functional status and also severe thrombocytopenia. In such cases, the health care team should provide the patient’s family with adequate information regarding the pros and cons of palliative chemotherapy at this stage of the cancer trajectory. The team should emphasize that supportive care is aggressive treatment, as well as focusing on symptom management and comfort.

**Decision-Making: Accept, Reject, or Continue**

After the initial shock of receiving a cancer diagnosis, patients and families must battle anxiety-provoking concerns such as dying from the disease, financial burdens, disease-related pain, and treatment-related toxicities. Chemotherapy is often perceived as an extremely toxic treatment by the general public. These concerns are very much related to patient and family decision-making processes, especially when the intent to treat is to palliate symptoms. Slevin and associates investigated the differences between patients’ attitudes to either mild or intensive cancer chemotherapy and the attitudes of health care providers such as physicians and nurses. Cancer patients were more likely to accept intensive treatment with debilitating toxicities in exchange for an extremely small probability of cure,
prolongation of life, and symptom relief. Medical oncologists were more likely to accept aggressive treatment than were general practitioners. Oncology nurses, not surprisingly, were more divided on the aggressiveness of treatment. The nurses’ perceptions fell between aggressive treatment and wanting more information on the benefit-to-toxicity ratio.

Silvestri and coworkers conducted a study to determine how patients with advanced non-small-cell lung cancer value the tradeoff between the survival benefit of chemotherapy and its toxicities. Data were qualitatively collected through the use of three scripted scenarios. Patients’ willingness to accept chemotherapy varied widely (n = 81). Many would choose chemotherapy for a likely survival benefit of 3 months only if the treatment positively affected QOL as well. The investigators found that the conflict between patients’ preferences and the actual care they received greatly affected their decision-making. It appears that some patients did not receive the treatment they would have chosen had they been fully informed in their previous choice of treatment.

Koedoot and colleagues investigated patient treatment preferences and decision-making processes in regard to palliative chemotherapy or best supportive care. The actual treatment decision was the main outcome of the study. At baseline, the majority of subjects preferred to undergo chemotherapy rather than watchful waiting. The majority of subjects also eventually chose treatment with chemotherapy. Treatment preference and a deferring style of decision-making were predictors of actual treatment choice. Treatment preference is positively explained by striving for length of life and negatively by striving for QOL. The results indicated that it is still questionable whether the purpose of palliative chemotherapy is made clear to patients. This emphasizes the need for health care providers to attach further attention to the process of information-giving and shared decision-making in patients with advanced cancer.

The Role of Nurses in Palliative Chemotherapy

The incorporation of chemotherapy into the palliative care setting has been shown through randomized clinical trials and meta-analyses to have survival benefits for patients with advanced cancer whose disease is incurable. However, these benefits are seen only in patients with higher baseline performance status and in those who are asymptomatic from their metastatic malignancies. Hence, it is evident that palliative chemotherapy, although effective in palliating certain disease-related symptoms, has limited benefits for all advanced cancer patients. Therefore, it is important for nurses, as integral team members in the transdisciplinary approach of oncology palliative care, to support patients and families through the difficult path of answering the quintessential question: to treat or not to treat? Nurses can help alleviate further anguish and suffering for patients with advanced cancer and their families in three crucial areas related to palliative chemotherapy: change in treatment intent, decision-making, and supportive care through treatment choice.

Change in Treatment Intent

When curative intent of treatment becomes impossible, practitioners should begin to address the intent to treat as palliation of disease-related symptoms. This initial communication is traditionally the domain of the treating physician. However, with more and more collaborative practices emerging between nurses, advanced practice nurses (APNs), and physicians, it is becoming apparent that a transdisciplinary approach offers the best support for patients and families during this difficult and vulnerable time. Communication of difficult news should best be conducted in a prearranged consultation session in which the treating physician, nurse, and social worker together deliver the information to the patient, the family, and other individuals who are integral to the decision-making process. Nurses can foster this transdisciplinary approach of delivering difficult news through collaboration and communication with experts across disciplines. Nurses are often the first to recognize the need for dialogue between the health care team and the patient/family regarding treatment intent and prognosis. Hence, nurses can advocate for patients by recommending and organizing these important communication sessions in order to alleviate unnecessary suffering for patients and families.

CASE STUDY
Mr. L, a Patient with Metastatic Esophageal Cancer

Mr. L, a 56-year-old Hispanic man who emigrated from Mexico City to the United States 20 years ago, has metastatic esophageal cancer. He has been treated with first-, second-, and third-line palliative chemotherapy. He wanted to be aggressive with treatment despite his poor prognosis. Functionally, he has been doing well, and his disease- and treatment-related symptoms have been well controlled. He maintains a positive outlook on life and wants to remain functional as long as possible. Mr. L has a G-tube through which he receives all his nutrition and food due to severe dysphagia. A recent computed tomographic scan revealed progressive disease despite third-line palliative chemotherapy. Mr. L speaks some English and is accompanied by his wife, who speaks no English, and his daughter, who speaks fluent English, to talk with the health care team about the next steps in his treatment regimen.

In this case, a consultation session is warranted. The objective of the session is threefold: (1) to present the difficult news of further disease progression and failure of third-line treatment; (2) to reevaluate treatment intent; and (3) to make recommendations for treatment. An interpreter should be at hand during the session to make sure that the patient and the family understand the situation. Before divulging the difficult news, it is important to assess for cultural needs in terms of
communicating bad news. The health care team should understand how much information patients want to know and how much they already know. This assessment guides the consultation session. If supportive care experts such as a psychologist or chaplain are not available to be present during the session, it is vital that they be accessible to intervene during this very difficult and sensitive time of the cancer trajectory.

Decision-Making

Once the change in treatment intent has been discussed, the next step is to guide patients and families through an informed decision-making process to either continue on aggressive treatment or focus on symptom relief. Again, this information should be delivered in a setting where all practitioners involved in the care of the patient and family are present. If this scenario is not possible, it is imperative for members of the health care team to communicate and follow-up with each other in regard to details of the information disclosed to the patient and family. In presenting this information, it is important to avoid the use of medical jargon and to use resources such as information leaflets and diagrams to assist the patient and family in informed decision-making. Nurses, having expertise in educating patients and families, can facilitate the availability of these visual resources and present them to patients and families.

Some patients might find it helpful to meet other similar patients or to access supportive care services such as psychology or chaplaincy. Nurses can encourage and facilitate these desires by initiating referrals to these services. A compassionate and ethical approach to review the medical situation with the patient and family is essential to providing them with an informed assessment of possible treatment choices. It is important to include in the treatment choices the use of hospice services and nonchemotherapy palliative care, depending on the patient's individual situation. Another important aspect to consider is the awareness of specific cultural needs and differences. Patient and family desires for open communication and participation in decision-making are greatly influenced by both ethnicity and religion, so it is important to assess these needs and ensure cultural sensitivity before presenting the information.

When discussing the possibility of palliative chemotherapy as a treatment choice, it is essential, before presenting statistical evidence, to learn about other specific factors that may affect the decision-making process. Nurses can facilitate and perform the assessment to obtain this vital information. Questions should focus on the following factors: (1) questions and decisions that need to be addressed in the patient's or family's lives, (2) a special upcoming event or specific unfinished business that must be completed, and (3) fears about dying or spiritual issues that need interventions from other supportive care services. Nurses can play a particularly important role in facilitating information gathering on the third factor: fear of dying and spiritual needs. Fear of dying and spirituality represent a much-ignored area in the general medical literature but have been shown to have significant impact on the QOL of cancer patients, especially when disease is incurable. Nurses can facilitate the patient's and family's search for spiritual understanding of their situation and alleviate existential suffering by first acknowledging patient's fears and distress. Facilitation of open communication regarding existential suffering can help alleviate fears of dying. Nurses must be compassionate listeners and allow patients and families a forum to discuss their deepest fears concerning the seemingly impending and inevitable terminality of their disease.

Supportive Care through Treatment Choice

If palliative chemotherapy is the treatment choice, support for patients and families through treatment becomes the most important objective for nurses. Education regarding the common and expected side effects of the specific chemotherapy regimens can foster a sense of control over symptom management and prevent unnecessary anxiety-provoking episodes related to poorly managed side effects. The use of written materials that list and explain common side effects can be helpful in facilitating the learning process for patients and families. Most importantly, nurses can assist in the continuous assessment of patient and family needs, focusing not only on the physical but also on the psychological, social, and spiritual domains. Communication during this difficult and vulnerable phase of the disease trajectory is key to the success of quality cancer care. Nurses can serve as a bridge of communication by fostering continued dialogue on the goals of treatment between patients/families and the health care team. This bridge of communication, although often difficult to sustain, is essential in a truly transdisciplinary model of care. Open and clear communication among health care team members can guide the assessment of patient and family needs but can also alleviate suffering by maintaining consistency in the amount and types of information provided. Inconsistencies in vital communication factors in palliative chemotherapy, such as treatment intent, often create false hopes and distress for patients and families.

If palliative chemotherapy is not the chosen plan of treatment, patients and families frequently experience a profound sense of abandonment. This sense of abandonment is most often directed toward health care providers. Patients and families, after living through the initial treatment phase of the cancer trajectory wherein follow-up with physicians and nurses is routine, suddenly lose the security of being assessed on a regular basis. Nurses can assist in alleviating this sense of abandonment through reassurance that follow-up care will still be in place. If referral to hospice is warranted, nurses can act as a liaison to attending physicians and hospice services to foster a smooth transition between care settings and maintain continuity of care.

Clinical Trials and Advanced Cancer

Several reports published or commissioned by government advisory boards such as the National Cancer Policy Board and the Institute of Medicine noted that the quality of end-of-life
care in the United States is seriously deficient. Many oncology professional organizations assert that hospice is the best-developed model of end-of-life care in the U.S. health care delivery system. Hospice offers quality palliative care using a transdisciplinary approach. With the rising interest in palliative care for terminally ill patients, there has also been a dramatic increase in interest regarding palliative care specifically for advanced cancer patients.

Patients with advanced cancer are often offered the opportunity to enroll in a phase I clinical trial. Although research on new therapeutic agents is crucial to the oncology specialty, it is not uncommon that patients who enroll in phase I trials are forced to forgo the utilization of services such as hospice and palliative care. This dichotomy is primarily a result of U.S. federal policy. Medicare and insurance policies deny hospice coverage to patients with terminal cancer who enroll as participants in phase I studies. Yet, it is precisely this population of cancer patients who would benefit from comprehensive palliative care. It is important to note that phase I studies are designed to determine the toxicity and maximum-tolerated dose of potential treatments, mostly for currently incurable cancers. These studies are not designed, and do not have the intended purpose, to have a therapeutic effect. In fact, studies have shown that therapeutic effects from cancer investigational therapeutic agents occur in only 2% to 4% of subjects enrolled in a phase I clinical trial. It is also ironic that the entry criteria for phase I trials is similar to the disease state criteria for admission into hospice—but it is precisely this dichotomy that renders a patient ineligible for the quality palliative care services that hospice provides.

Patients who enter investigational cancer trials participate, in part, because of protocol eligibility such as disease and functional criteria. Many advanced-stage cancer patients who make decisions to participate in cancer clinical trials are also characterized by a highly motivated personality. They feel that active treatment is best for them. Other factors identified with enrollment may include altruism and the influence of the physician. Patient expectations include a response to therapy, a reduction in symptoms, and improved and increased communication with their physicians. Therapeutic efforts are often equated with superior QOL and are measured against no other options. By contrast, patients and families believe palliative care is a passive choice, the equivalent of “no care.”

When faced with decision-making regarding their plan of care, patients with advanced incurable cancers often do not fully understand the choices that are available to them. Patients who would qualify for hospice services as regulated by Medicare have very little understanding of admission criteria and services rendered. It is unlikely that patients who are potential study participants understand fully that to enroll in a clinical trial means that they must temporarily forgo the opportunity of receiving comprehensive palliative care. Furthermore, there are no informed consent documents that disclose the risk of losing hospice benefits when enrolled in a clinical trial. Within the informed consent documents for cancer investigational therapeutic agents, there are no descriptions in the benefits and risks section that address the risk of temporarily losing hospice eligibility. This loss of eligibility is not permanent; rather, patients and families can enroll and disenroll from hospice benefits whenever they choose. However, with the shortened life expectancy for advanced cancer patients, the decision to forgo palliative care at the initiation of investigational therapeutics is a crucial barrier to accessing aggressive supportive care at a time when patients and families need it the most.

Tensions Between Palliative Care and Clinical Research

Despite significant progress in research and treatments, the diagnosis of cancer creates fear and turmoil in the lives of every cancer patient and the family. Cancer disrupts all components of social integration—family, work, finances, and friendships—as well as the patient’s psychological status. Over the extended course of the illness, physical changes and deterioration create multiple and complex demands on the patient and family. These demands, in conjunction with significant financial assaults, generate a negative synergy, which is often ignored in the care of patients with advanced disease.

Patients with advanced, incurable cancers are especially vulnerable and therefore have many unique needs in coping with their disease. Hence, it is helpful to tailor treatment to the specific needs of each individual and family, in order to fulfill personal goals and maintain QOL. This is precisely what a comprehensive palliative care program can provide. At the same time, many patients faced with the terminality of their disease want and seek new innovative therapies. In the absence of further evidence-based and effective standard therapy, clinical trials offer a sense of hope for a potential cure. But for patients who choose to participate in a clinical trial, there are often no guarantees of benefit, and there is the added possibility of harm and discomfort in the form of physical and psychological distress.

The impact of clinical trial participation on physical symptoms related to advanced cancer is complex, and there is a paucity of data regarding the extent of these symptoms. Experimental agents, like standard treatment agents, cause side effects. The difference in the side effect profile of a well-established agent versus an experimental agent lies in the anticipation of symptoms. Well-established agents have well-documented side effect profiles that can be anticipated and predicted and therefore better controlled or even prevented in certain situations. The novelty of experimental agents, however, renders their side effects unpredictable. There is a tremendous amount of uncertainty about what effects an experimental agent might have on a particular patient.

Palliative care stands in contrast to disease-directed therapy at most cancer centers in the United States. The rift between them creates a dissonance for development of clinical research protocols and for recruitment of some groups of patients into cancer clinical trials. Only one third of all cancer patients receive formal palliative care through hospice, and often this
occurs only in the final days of life. Although advanced cancer should be a time of focusing and resolution, the hospice referral process often occurs during crisis situations. As disease advances, a positive relationship exists between increased physiological symptom severity and the patient's level of emotional distress and overall QOL. An inability to complete end-of-life tasks may lead to patient dissatisfaction as well as complicated family/caregiver stress and grief after the death. Yet, anecdotal evidence from clinical practice indicates that some patients will participate in investigational therapy precisely because they do recognize that QOL is mostly related to functional ability. These patients are unwilling to participate in clinical trials because they perceive that enhanced longevity is unlikely. This cohort of patients, therefore, is lost to clinical research.

Quality of Life Concerns for Clinical Trial Participants

Although the structure and requirement of a clinical trial protocol mandates the inclusion of a plan of action for unexpected physical symptoms, these plans are often focused on pharmacological interventions only. For example, if nausea and vomiting is an anticipated or expected side effect, a protocol of which antiemetic agents to use is written into the clinical trial protocol itself. However, the psychological and social distress from this side effect is not included in the plan. A clinical trial protocol generally does not include plans that specifically state the need for referrals to other allied health professionals such as palliative care specialists and psychologists.

The psychological and cognitive symptoms of patients participating in research studies vary. Some patients may be distressed to be told that they are not eligible for inclusion into clinical trials. Research subjects may also have difficulty when an experimental treatment fails, which often mandates the withdrawal of subjects from the treatment protocol. One potential advantage of enrollment in clinical trials is that several members of the research team care for these patients. There are regularly scheduled visits, and that attention may affect the patient's psychological well being. This added attention might lead to early detection of psychological symptoms that are indicative of depression, sadness, anxiety, or irritability. Subtle changes in psychological effects might be readily detected by research personnel, and nurses are an integral part of this team. However, in order for this added attention to be beneficial to patients and families, it is important for research teams to work collaboratively with allied health professionals and palliative care specialists to address concerns in all areas of patient and family well-being.

Economic demands and caregiving needs may also be affected by clinical trial participation. Financial burdens may be increased for clinical trial participants even if the experimental agents are provided free of charge. The usual intensive monitoring and testing that can sharply increase with participation in clinical trials may not be covered by either the trial budget itself or the patient's insurance. The frequent visits for treatment, physician assessment, and various other procedures that are often mandated in clinical trial protocols may incur further economic burdens in terms of expenses for travel and room and board.

The needs of caregivers and families may also change with clinical trial participation. Families experience tremendous physical, psychological, social, and spiritual concerns that are related to the patient's well-being. Physical symptoms such as fatigue can plague caregivers and families who are faced with the complex care of patients with advanced cancer. The complexity of navigating through the health care and insurance systems can place tremendous burdens on patients and caregivers both. Social exposure may be diminished for caregivers, because much of their days are spent on caring for their loved ones. Finally, the agony of being a witness to a loved one's suffering and the prospect of grief and bereavement in terminal illness may present caregivers with spiritual and existential distress.

Attending to the spiritual and existential needs of patients with advanced cancer is an important factor in the overall experience of patients and families facing the inevitability of terminal illness. It is often at this point in the cancer trajectory that patients experience the needs of altruism. Patients and families who recognize the diminishing hope of survival may find comfort and solace in the possibility of contributing to the advancement of science through participation in clinical trials. Others may choose to focus on using precious time to concentrate on more personal goals, such as unfinished business and QOL.

CASE STUDY

Mr. H, a Patient with Metastatic Colorectal Cancer

Mr. H is a 45-year-old African American real estate agent with metastatic colorectal cancer to the liver. He lives with his partner and primary caregiver, Ms. S, and his 14-year-old adopted son. Ms. S has voiced concerns about Mr. H's comfort, which is worrisome for the whole family. His symptoms primarily involve pain and ascites. Both first-line and second-line chemotherapeutic treatments have failed. Mr. H recently started a clinical trial treatment. Unfortunately, his disease progressed 2 months after initiation of the clinical trial treatment. His ascites has increasingly worsened. Lately, Ms. S has become increasingly tearful while accompanying Mr. H during his clinic visits.

In this case, it is clear that the caregiver is suffering tremendously. After surviving through several bouts of chemotherapy without much effect on the tumor, the impact of repeated discouragement weighs heavily on the patient's and caregiver's hearts. Ms. S has probably witnessed and supported Mr. H through the agonies of treatment and continued progression of disease. One can anticipate that they will experience tremendous difficulties with regard to grief and bereavement, as well as their son. It is important, therefore, to recommend or establish...
support for the family. In this case, referral to supportive care experts might be warranted. The family should be provided with information on other types of support, such as support groups. It might be helpful to connect them with other caregivers, to exchange experiences on caring for a terminally ill loved one, and for the son to connect with other adolescents who have lost a parent.

**Simultaneous Care: A Model Linking Palliative Care to Clinical Trials**

The Simultaneous Care Model was developed at the University of California Davis as a means to demonstrate that investigational therapy and palliative care can be provided simultaneously. The theoretical framework for this model addresses the flaws in the provision of palliative care for clinical trial patients. In the development of the model, it was hypothesized that the simultaneous delivery of investigational therapy and a structured program of supportive care would result in measurable improvements in predefined outcomes without adverse events for patients, caregivers, or the physician–patient interaction. The model envisions palliative care as timely and team oriented, longitudinal, collaborative, and comprehensive.

A pilot study was conducted to test the feasibility and preliminary efficacy of a problem-solving educational intervention for patients enrolled in clinical trials. All patients entered onto a University of California Davis phase I or phase II cancer investigational therapy protocol were considered eligible for Simultaneous Care protocol entry. Participants in randomized phase III studies were allowed if they compared different chemotherapy regimens for advanced disease.

Consented patients who lived within the service area of the University of California Davis Hospice Program (roughly a 25-mile radius) received Simultaneous Care. Patients who lived outside the service area received Usual Care. The Usual Care or nonintervention group was used as a control cohort in this nonrandomized pilot study.

Simultaneous Care patients were assigned a nurse trained in both cancer chemotherapy and palliative care and a social worker with inpatient, clinic, home health, and hospice patient care experience. The nurse visited the home two to three times a week or as needed, and the social worker visited one to two times a week or as needed. They accompanied the patient and the family to most physician visits. The nurse focused on chemotherapy toxicity, symptom management of advanced cancer, and care coordination. The social worker focused on emotional support issues, family and interpersonal issues, and end-of-life planning.

Sixty-four patients were enrolled into the pilot study. Forty-four patients entered the intervention or Simultaneous care arm, and 20 entered the nonintervention or Usual Care arm. Of 10 physicians eligible to enroll patients, 10 entered patients into the Simultaneous Care protocol. A greater proportion of patients in the Usual Care group had genitourinary tumors (11/20 versus 6/44), whereas non-small-cell lung cancer was more frequent in the Simultaneous Care group (17/44 versus 3/20). No patient disengaged from Simultaneous Care as a result of discussions of end-of-life issues, palliative care discussions, or conflict between investigational therapy and palliative care goals or providers. The qualitative consensus, derived from physician questionnaires given to each physician for each patient, was that the cancer center personnel not only encouraged Simultaneous Care but also came to expect the nurse and social worker as routine support, potentially redefining Usual Care.

Of the 44 Simultaneous Care patients, 35 died with hospice, 3 died on therapy, 4 died without hospice, and 2 were alive and off therapy without hospice at the time of report. Of the 20 Usual Care patients, 7 died without hospice after therapy was completed, 8 died in a hospice program, and 5 remained alive at the time of report. The median number of days in hospice was the same for both cohorts, but the mean was higher in Simultaneous Care group (54 versus 37 days). Among those who died after completion of therapy, the proportion that entered hospice programs was greater in the Simultaneous Care group (92% versus 53%). Patients in Simultaneous Care received a mean of 3.8 cycles of chemotherapy, and those in Usual Care received a mean of 4.5 cycles.

The results suggest that palliative care can be introduced simultaneously with investigational cancer therapy without adverse events. That is, the introduction of palliative care along with disease-directed therapy neither undermined patient participation in clinical research nor adversely affected the patient/physician relationship. Patients are not asked to choose between two reasonable options, disease-directed therapy and palliative care. Rather, they have an opportunity to receive both, each with a different set of goals, benefits, and burdens. This model of care may also enhance the coordination of care from the home to the clinic or cancer center. The model may assist in the introduction of end-of-life issues early enough for patients and families to benefit fully from specialized supportive care programs including hospice. Currently a multisite, randomized, controlled phase II study of the efficacy of Simultaneous Care is underway, funded by the National Cancer Institute (NCI).

**Perspectives Toward Clinical Trials: Patient versus Nurses**

The conduct of clinical trials involving human subjects raises ethical concerns for health care professionals. In the process of decision-making in a clinical trial setting for patients with advanced cancer, the impact of nurses presents an additional element. Nurses are involved in clinical trials both as clinical investigators and as caregivers for patients and families undergoing experimental treatments. In the clinical setting, nurses facilitate practitioner–patient communication and also serve as advocates. Nurses often spend a considerable amount of time with patients and their families, and they are acutely aware of attitudes, needs, and concerns regarding participation.
Burnett and coworkers conducted a study to identify nurses’ attitudes and beliefs toward cancer clinical trials and their perceptions of the factors influencing patients’ participation. A 59-item questionnaire was administered to nurses working in NCI-designated comprehensive cancer centers. Of the 417 nurses who responded, 96% reported that participation is important to improving standards of care, but only 56% believed that patients should be encouraged to participate in these clinical trials. As a group, research nurses were more likely to have favorable views toward clinical trials and also about patient understanding regarding treatment plans and goals. On the other hand, nurses working in intensive care units and bone marrow transplant settings had more concerns regarding patient understanding and patient–physician communication. Ninety-two percent of nurses reported that patients entered a clinical trial with the belief that it would cure their cancer. Sixty-eight percent of nurses reported the belief that patients participate in clinical trials because they hope to receive better medical care. Nurses also indicated their perception that nurses as professionals are more likely to respect patients’ wishes and less likely to apply pressure on patients regarding clinical trial participation. These results indicate the concerns that nurses working in oncology settings have toward the informed consent process of clinical trial participation and strongly suggest the need to develop nursing interventions to better support this process.

Aaronson and associates conducted a study to test the efficacy of a telephone-based nursing intervention on improving the effectiveness of the informed consent process in cancer clinical trials. This randomized study compared the effectiveness of this nursing intervention in patients who were randomly assigned to either a standard informed consent procedure based on verbal explanation and written information or the standard informed consent process plus the supplementary telephone intervention (intervention group). Results showed that the intervention group was significantly better informed about the following: (1) the risks and side effects of treatment, (2) the clinical trial context of the treatment, (3) the objectives of the clinical trial, (4) the use of randomization in allocating treatment (if relevant), (5) the availability of alternative treatments, (6) the voluntary nature of the participation, and (7) the right to withdraw from the clinical trial. The intervention did not have any significant effect on patients’ anxiety levels or on the rate of clinical trial accrual.

Cox conducted a qualitative study to identify the psychosocial impact of participation in clinical trials, as experienced by the patients themselves. The study sought to interpret patients’ ways of coping with their individual situations and also to identify the consequences of trial involvement. Of the 55 patients involved in the study, the offer of a trial treatment was seen as a turning point for patients. Thirty patients (54%) described the offer of participation as being “the light at the end of a tunnel” because they perceived that hope was offered. On the other hand, 58% of subjects described how the trial generated uncertainty, and 54% felt special, privileged, pleased, lucky, and honored to have been offered participation. The majority of patients interpreted the offer of trial participation as being the right plan of action because their physicians offered it. Reasons for patients to accept trial participation included the desire to be in expert hands (54%) and the desire to help others (52%).

As clinical trial initiation began and patients progressed through treatment, an overwhelming sense of being burdened by trial involvement was seen in all cases. These burdens focused on side effects and additional demands such as blood tests and scans. It was evident that these trial burdens were not fully anticipated by patients at the beginning of trial involvement. Nevertheless, most of the patients desired to persevere through treatment instead of withdrawing.

At the conclusion of participation, patients expressed disappointment that the trial drug was not successful. An overwhelming sense of abandonment was a feature in all patients. Subjects were also eager to receive feedback on the trial in which they had participated. Trial withdrawal due to disease progression or toxicity was a common feature for subjects in this study. Trial withdrawal and conclusion was a deeply distressing and stressful challenge for all patients. In addition to having to confront the realities of having a terminal illness and the lack of response to their last hope for “cure,” patients also experienced a dramatic decrease in contact from health care providers, which inevitably led to an overwhelming sense of abandonment. These findings suggest that patients and families need support during and beyond the trial to deal with the disruption that clinical trial participation might have on the overall trajectory of care. The investigators suggested that one way to overcome these issues is to consider early clinical trials in the context of a continuing palliative care program in which the duty of care extends beyond trial involvement and in which all patients meet and dying concerns can be addressed.

The Role of Nurses in Caring for Clinical Trial Patients

Clinical trials of new investigational cancer therapeutics are a necessary component to the process of translating scientific discoveries into standard practice of care. Oncology nurses have many different roles in the conduct of cancer clinical trials. First and foremost, the process of obtaining true informed consent is a critical factor, not only in improving patient accrual into clinical trials but also in the overall well-being of patients and their families. The informed consent process is an opportunity to provide accurate information regarding important factors that affect the patient’s and family’s decision-making process in advanced cancer. These factors include trial procedures and potential risks and benefits. The initial informed consent process is also a time to correct any misconceptions and allay unfounded fears, and to provide sufficient time for patients and families to thoughtfully consider clinical trial participation. A predecisional support process provided by oncology nurses may influence the soundness of patients’ decisions to enroll in clinical trials.
would assist in well-considered decisions include helping patients gather additional relevant sources of information, describing patients’ roles and rights in studies, encouraging patients to define their own reasons for participating in clinical trials, and supporting patients in making decisions that correspond with their personal values and wishes.44

Nurses can also assist in educating not only clinical trial patients but also the extended community. Interventions aimed at increasing community awareness can foster better understanding of clinical trials and their importance in the advancement of treatment options and strategies for oncology patients.45 The formation of clinical trials support groups for patients and families considering enrollment in research is another strategy that may provide necessary education and social support.46 Strategies such as follow-up phone calls or e-mail messages while patients are considering clinical trials participation can have a positive effect on the decision-making process.43

Nurses are in an ideal position to promote awareness of the importance of clinical trials and subsequent improvements in patient care. The three key roles of nurses caring for clinical trial patients and their families are educator, patient advocate, and study coordinator.47 As patient and family educators, nurses can have a tremendous impact on a patient’s experience with clinical trial participation. Nurses are clinical interpreters who provide patients and families with explanations of highly complex and intricate protocols without using medical jargon.43 Education about the specific protocol process, expectations at each stage, management of side effects, and the importance of communicating changes in health status to practitioners is integral to the oncology research setting.

As patient advocates, nurses play an important role in the critical gateway to clinical trial participation—the informed consent process.45 Nurses bring to this role a patient-centered, holistic method of support. The nursing perspective is important in that it provides a framework within which patients and families are treated with dignity and respect. Clarification of reasons behind decisions to participate—whether physical, psychological, social, or spiritual—should be encouraged.

APNs such as clinical nurse specialists and nurse practitioners can be an important factor in the conduct of clinical trials. Expertise in symptom management and clinical problem-solving is a key asset for APNs in the research setting. For example, nurse practitioners working in a clinical trials setting have an expanded scope of practice that allows them to perform routine follow-up physical examinations as well as diagnose and manage treatment complications.26 This level of participation in patient and family care may enhance patient satisfaction, compliance, and retention.

**Summary**

Of all the topics to which oncology health care providers, palliative care specialists, and ethicists have devoted their attention, few raise as much heated debate as the dichotomy between active treatment and palliative care. The use of palliative chemotherapy and clinical trial participation as a treatment option for advanced cancer patients has been in the heart of this debate for decades. There is a growing movement in the United States to integrate palliative care into clinical trials. However, there is still much work to be done. Frustration lies in the assumption that subjects who are actively treated for symptom palliation, whether through palliative chemotherapy or experimental agents, must forgo a coordinated plan of care that involves quality palliative care.46 It has become increasingly evident that this dichotomy should not exist; that is, patients and families can simultaneously receive therapy for palliation of symptoms and also have access to quality palliative care. It is also increasingly evident that this quality care can be provided only through a transdisciplinary model of care. Nurses can help alleviate the tension between palliative care and disease-directed therapies through education, advocacy, and coordination of care. It is only by removing this dichotomy that patients with advanced cancer and their families can be provided with the highest quality of information to facilitate their decision-making process.

Pediatric Palliative Care
Key Points

- Children are living longer with complex chronic medical conditions.
- This life prolongation may be accompanied by multiple acute and chronic health crises and challenges for the child and family.
- Symptom management for these children presents a unique challenge to health care providers.
- Skilled and compassionate management of symptoms, with a family-centered approach, is an integral part of the care of a chronically ill child.

Complex chronic conditions of childhood (Table 49–1) are defined as “any medical condition that can be reasonably expected to last at least 12 months, involves either multiple organs or one organ system severely enough to require specialty pediatric care, and some probability of hospitalization at a tertiary care center.” Currently, there are limited estimates on the numbers of children living with these disabling and potentially life-limiting complex chronic conditions. Newacheck and Halfon estimated that approximately 4.4 million children in the United States currently live with some level of disabling chronic condition, and that roughly 450,000 of those children have conditions that prevent participation in age-appropriate activities, result in significant limitation in school, and account for increased numbers of hospitalizations and contacts with the health care system. Feudtner and colleagues reviewed death-certificate data from 1979 to 1997 and reported that 21% of the 1.7 million child deaths during that time were the result of a complex chronic condition.

In the past 2 decades, child-mortality trends have shown a decrease in numbers of deaths from complex chronic conditions in middle childhood years, with stable to increased numbers of deaths in late adolescence and early adulthood. This trend most likely reflects the ability of advancing medical science to provide life-prolonging management of children with complex chronic conditions. However, this life prolongation often comes at the cost of multiple acute and chronic health crises and challenges for the child and family, as well as increasing debilitation as the child’s condition progresses, thereby increasing the possibility of suffering for the child and family. Medical science therefore must face the challenge of recognizing and attending to suffering as a concurrent obligation to providing scientifically based curative and life-prolonging treatment. Unfortunately, fragmentation of health care, limited acknowledgment of terminal care needs of children, and a paucity of research on the impact of symptoms on quality of life and interventions aimed at managing distressing symptoms all create challenges in alleviating suffering for children with complex chronic conditions.
This chapter focuses on issues related to the assessment and management of common nonpain symptoms in children and adolescents with complex medical conditions in the advanced and terminal stages. The unique issues related to children dying in pediatric and neonatal intensive care units are addressed in Chapters 52 and 53, respectively.

Assessing Sources of Suffering in Advanced Childhood Illness

Family-Centered Care

Family-centered care is based on the understanding that the family is the child’s primary source of strength and support and that the perspectives and information provided by families, children, and young adults are important in clinical decision-making. In considering symptom management within the context of family-centered care, it is necessary to assess the family system as a whole, as well as its individual members, to identify all sources of suffering that may require intervention. Interdisciplinary collaboration with chaplains, social workers, psychologists, and child-life therapists will contribute to the overall assessment of the ill child, parents, and siblings.

The focus of family-centered care is to develop a process of shared decision-making over the course of the child’s and family’s illness experience that is based in the interpersonal relationship between the child and family and their health care providers. The physician and health care team must come to know the child and family as individuals and provide diagnostic, prognostic, and treatment information in a manner sensitive to the particular child’s and family’s experiences, values, beliefs, and available social and spiritual support. Parents and children should be respected as the experts in their illness experience and management, and value must be given to their contribution to the plan of care. The child’s and family’s illness experience and goals of care, as well as the impact of a particular symptom on suffering and its effect on the child’s function and quality of life, will influence the types of interventions considered as symptoms occur.

Illness Experience and Sources of Suffering

Research exploring the experiences of families of children with complex chronic conditions provides a glimpse into their world. Uncertainty prevails as the parents move from the initial suspicion that something is wrong with their child to the confirmation that this is indeed the case. Parents struggle to cope with the diagnosis and learn skills necessary to provide technical care and negotiate the health care system for needed services and information. Over time, as treatment continues, parents must live with ongoing uncertainty regarding the unpredictability of the illness, the ultimate outcome of their child’s treatment, the challenges of parenting a seriously ill child, and the possibility of death. The child may experience disability, physical

pain and other distressing symptoms as a result of the disease and treatments, severe alterations in their social world, and disruption of their developmental process.20-24 Siblings may experience feelings of anger, guilt, anxiety, depression, and social isolation.25-29

While the above picture gives an impression of tremendous struggle and individual distress in the family, there is also research that suggests there are aspects of family functioning that facilitate coping with this new family reality. Parents' adaptation and adjustment to their child's illness is facilitated by several factors, including gaining information regarding the disease, its treatment, and prognosis; good spousal communication, similar coping styles, and means of emotional expression; and sufficient social support.5,30-32 Factors associated with adaptation of the ill child and siblings include having open communication and emotional support from parents during times of stress, having a wide range of coping skills, seeking information about the disease, and clarifying fears.33-38

Assessing and understanding the child's and family's unique experiences during the illness trajectory provides the health care team with insight into what symptoms may contribute to the family's suffering. This assessment involves hearing the child's and family members' "story" as they have lived it during the course of the disease. It is important to elicit care that has been helpful in past experiences with the illness as well as care that was not helpful. Insight into what the family values regarding the role of spirituality or faith in God, the meaning they give to their experience of illness, and what activities or interactions the child and family identify as contributing to quality of life provide a context for identifying and managing symptoms that contribute to suffering for the child and family.

**Expectations and Goals of Care**

Children with complex chronic conditions are a highly diverse population, with a variety of illness trajectories that are often characterized by prognostic uncertainty, including sudden unexpected death, death from potentially curable disease, death from lethal congenital anomaly, and death from progressive conditions with intermittent health crises. The unpredictability and uncertainty of many of these disease trajectories often result in ongoing medical treatments aimed at cure or aggressive life-prolongation, with little attention to the suffering of the child or family.5

In general, goals of care for children with serious, life-threatening, or limiting illness as they progress through their illness trajectory include interventions aimed at cure, life-prolongation with or without aggressive life-sustaining therapies, and care focused solely on interventions aimed at treating discomfort from symptoms as the disease moves into its terminal phase. Ideally, these goals would shift as the child, family, and primary health care team discussed changes in quality of life, symptoms, and prognosis over the disease trajectory. It is very important that interventions aimed at maintaining maximal comfort and quality of life occur throughout the disease trajectory as well as through the terminal stages. Unfortunately, for many families, the presence of a DNR (do not resuscitate) order often leads to health care professionals dismissing treatable illnesses or symptoms as "part of the dying process," thereby contributing to suffering for both the child and family.

The most difficult decision a parent must face is to change the focus of care from cure or aggressive life prolongation to focusing on comfort and terminal care. Wolfe and colleagues22 reported on disparity between parents and health care providers regarding the realization that a child with progressive cancer had no realistic chance for cure. Parents who came to that realization earlier were more likely to discuss hospice care, to establish a DNR order, and to change the focus of care from cancer-directed therapies to treatments focused on controlling discomfort, and thereby experienced greater quality of home care.

Parents have reported that decisions to forgo further aggressive medical treatments and instead pursue care focused on comfort and quality of life occurred only after realizing that ongoing aggressive treatment would not bring about cure or further life prolongation, and they recognized the physical deterioration and suffering of their child. Once this realization is reached, parents report that the child's wishes and quality of life are major determinants of treatment decision-making.39-41

The first step to managing symptoms of children with advanced and terminal illness is a thorough assessment of the child's and family's expectations and goals of care. Interventions aimed at controlling symptoms must be compatible with the family's understanding of where their child is in the disease trajectory and their expectations of care, as well as the child's overall functional status and quality of life. For instance, an adolescent with advanced muscular dystrophy may be attending school and participating in a religious community despite significant physical limitations. This level of function and quality of life may lead the child and family to desire aggressive ventilatory support for life prolongation in the event of an acute respiratory infection, with the hope that the child will be cured of the infection and resume his previous level of functioning. However, if the adolescent were home-bound and seriously debilitated due to progressive respiratory failure, he and his family may choose to pursue home management of respiratory discomfort without the use of ventilatory support to reduce suffering associated with intensive hospital-based interventions. In determining the expectations and goals of care with the child and family, it is important to discuss the balance between relieving and contributing to the child's suffering. The prevailing decision-making framework should not be based on whether an intervention is consistent with a palliative care focus, but, rather, whether the intervention under consideration would provide relief from or contribute to the child's and family's suffering.

**Physical Symptoms and Suffering**

Children dying as the result of complex chronic conditions experience a number of symptoms throughout their illness trajectory that can contribute to suffering and decreased quality of life (Table 49–2). Wolfe and colleagues22 reviewed medical
records and interviewed 103 parents of children with cancer in a U.S. tertiary-care children’s hospital. Generally, most of the children received aggressive life-sustaining treatments at the end of life, contributing to a substantial amount of suffering, primarily from pain and dyspnea. Of the parents surveyed, 89% stated that their child suffered “a lot” or “a great deal” from at least one symptom. However, symptom management was effective in only 8% for pain and 16% for dyspnea.

Similar findings were reported by McCallum, Byrne, and Bruera,23 who reviewed 30 cancer and noncancer deaths in a Canadian children’s hospital. The majority of children died in the intensive care setting despite aggressive measures, and symptoms were inconsistently documented. Little conversation was documented regarding the family’s preference for resuscitation or location of death, and only one case documented that the child had been informed of his condition.

Managing these symptoms requires that health care providers remain attentive in their assessment of the child’s physical and emotional symptoms. Assessment should include the child’s report of symptoms and how distressing he or she finds them, information based on parent observation of their child’s condition, and health care provider’s knowledge of the pathophysiology of the underlying disease. Diagnostic tests should be considered carefully for the potential discomfort they may cause. Tests should be ordered only if they will help determine an intervention. A test should be questioned for its appropriateness if the results will not change management (e.g., MRI to document growth of known terminal tumor).

As mentioned earlier, symptoms experienced by children with advanced and terminal chronic illnesses are often interrelated. If a child reports a distressing symptom, it is necessary to obtain a thorough assessment regarding the symptom’s onset, severity, and effect on function and quality of life. The health care provider must consider the likely cause of the symptom and determine the best course of intervention. For example, pain with urination may be related to an infection and amenable to treatment with antibiotics to cure the infection. Shortness of breath in a child with cystic fibrosis may be related to infection and amenable to treatment with antibiotics, with resolution of the symptom. However, it may also be related to progressive respiratory failure or disease progression. Oxygen therapy, opioids, ventilation and/or energy-conservation techniques may assist in relieving the severity of the symptom, but will not eliminate the underlying cause. This distinction is important to discuss with the child and parent with regard to the goal of treatment and expectation of care in relation to the child’s overall condition and quality of life.

Control of present symptoms as well as anticipation of distressing symptoms as disease progresses is imperative in attending to the suffering of children with advanced disease and their families. Following is a discussion of the most common symptoms associated with distress and suffering experienced by children with advanced illness. It is by no means an exhaustive presentation of all symptoms that children with complex chronic conditions may experience. Each symptom is discussed as to its general issues, causes, assessment, and pharmacological and nonpharmacological management. As discussed earlier, there is little evidence-based data on the management of non-pain symptoms in children with advanced disease. Much symptom management in pediatric palliative care is based on empirical approaches and extrapolation from adult hospice and palliative care literature.

An inherent difficulty in pharmacological management in pediatric palliative care is a lack of pharmacological dosing and side-effect information on infants, toddlers, and early school-aged children for many medications. Starting dosages of medications will vary depending on the age, weight, and clinical circumstances of the child. It is incumbent on physicians and nurses to consult with experienced pediatricians and pediatric hospice and palliative care providers for medication choices, appropriate doses, and titration for difficult cases of symptom management. For more information on pediatric pain management, see Chapter 55.

Management of Symptoms During Disease Progression and End of Life

General Systemic Symptoms

Fatigue. The most comprehensive research in fatigue experienced by children with complex chronic illnesses has been in the area of childhood cancer. Fatigue has been described by young children with cancer as a “profound sense of being physically tired, or having difficulty with body movements such as moving legs or opening their eyes”; and as a “changing state of exhaustion that includes physical, mental, and emotional

Anorexia/Cachexia. Loss of appetite occurs in nearly all children with terminal illness. Anorexia involves the loss of desire to eat or a loss of appetite, with associated decrease in food intake. Cachexia is a general lack of nutrition that occurs over the course of a chronic progressive disease. Anorexia and cachexia are multidimensional in nature and are influenced by disease, treatment and emotional factors (Table 49–5). These symptoms are particularly distressing to parents of children with illness because they cause concern that the child is “starving to death.” Food and meals have a social association with “caring,” and is significant in family culture, activities, and ritual. In most instances, children will request favorite foods as a means of comfort and familiarity. It is important to assist parents in understanding their child’s changing eating habits and nutritional needs as well as ways to redirect energies toward other caregiving activities. Table 49–6 provides additional suggestions for management of anorexia and cachexia.

Parents and health care providers often struggle with personal and ethical dilemmas regarding fluid and nutrition management for children with terminal illness. The act of withholding medically provided fluids and nutrition (GT feeds, TPN) is legally and ethically permissible for children with irreversible, progressive medical conditions when it is agreed upon by the health care providers and family that such medically provided nutrition will increase the suffering and discomfort of the child and would not alter the progression of the disease or the outcome of death. Such decisions are highly individual to the family and influenced by culture, religious tradition, and personal values.

Providing aggressive nutritional support does not usually improve the condition, and, in fact, may add additional symptom burden for the child. Unfortunately, there is no clear data to guide the discussion of the risks/benefits of providing aggressive fluid and nutrition in terminally ill children. When medically provided nutritional interventions are chosen by a family, the challenge is balancing fluid and nutritional supplementation as appetite and metabolic needs decrease with advancing disease. Ideally, as the child’s condition progresses, parenteral or enteral supplements can be slowly weaned to promote comfort and decrease symptoms of increased congestion or secretions. For more information on anorexia and cachexia, see Chapter 8.

Psychological/Emotional Symptoms

Anxiety. Children with chronic illness may experience a number of anxiety-provoking events throughout their illness. Episodes of serious illness, hospitalizations, painful procedures, changes in independence and physical abilities, uncontrolled pain and other symptoms, and an uncertain future all can contribute to fear and anxiety. The distinction between childhood fears and anxiety is crucial—childhood fears are specific and developmentally based (e.g., fear of the dark, fear of separation, fear of death), whereas anxiety is a generalized feeling of uneasiness without a known source. Anxiety and depression may be comorbid conditions.

Anxiety in terminal illness is an expected reaction and should be assessed frequently. Toddlers and young children will generally have anxiety reactions that are an extension of the stress and anxiety levels of parents and other family members around them. These reactions may include irritability, clinging, temper tantrums, and inconsolability. School-aged children and adolescents who can cognitively comprehend their illness and impending death may experience more adult-like symptoms such as chronic apprehension, worry, difficulty concentrating, and sleep disturbance. Chaplains, child-life
workers, and social workers are helpful in assessing children's fears, worries, and dreams. Children and adolescents under stress may regress behaviorally and emotionally; therefore, health care professionals should be alert to changes in the child's coping or personality.

**Depression.** Little is known about the incidence or prevalence of clinical depression in children and adolescents living with chronic illness. Depression can be described as a broad spectrum of responses that range from "expected, transient, nonclinical sadness, to extremes of major clinical depressive disorders and suicidality."49 Children are unique in their coping abilities, which are influenced by their age and developmental level. Often, during the course of terminal illness, most children remain future focused and continue to plan activities, even in the final days of life.

Risk factors for depression in chronically ill children include frequent disruptions in important relationships, uncontrolled pain, and presence of multiple physical disabilities.48 Existential factors related to impending death, concern for parents and other family members, and a personal or family history of preexisting psychological problems can also increase the risk for depression in chronically ill children. Suicidal thoughts or wishes are not common in terminally ill children and adolescents, but health care providers should be alert to comments about wishing to die and use social workers or child-life therapists to assist in further assessment and management.

Assessment of depressive symptoms must take into account the child’s developmental level. Pediatric social workers and child-life therapists are good resources for assessing a child’s emotional status. Somatic complaints such as lack of appetite, insomnia, agitation, and loss of energy may be the result of disease and cannot be considered hallmark signs of depression in ill children. More appropriate signs would include a persistent sad face and demeanor, tearfulness, irritability, and withdrawal from previously enjoyed activities and relationships. Siblings may exhibit persistent and significant decrease in school performance, hypersonmolence, changes in appetite or weight, and nonspecific complaints of not feeling well.48 Parents should be assessed for depressed appearance, fearfulness, withdrawal, a sense of punishment, and mood that cannot be improved with good news, and should be referred for further evaluation as needed.50

Pharmacological management of anxiety and depression should be considered if symptoms of anxiety and depression are debilitating. Consultation with appropriate psychiatric specialists for further evaluation and choice of agents is appropriate. Generally, management of anxiety and depression related to terminal illness in children involves nonpharmacological interventions aimed at addressing the underlying issues that are contributing to the symptoms. Both unconditional acceptance of the child’s feelings and reassurance are powerful interventions for anxiety and depression. Facilitating open communication between children and their parents may also be helpful. Creative arts therapies, play, relaxation, storytelling, music, and games may assist in helping children begin to talk about their feelings. It is important to recognize that a certain level of anxiety and sadness is normal when facing death. Health care providers must take caution to not be overly “cheerful” or insistent that a child discuss his or her feelings. Calm presence, active listening, and sitting quietly with a child will help to build trust. Adolescents in particular are very private about their thoughts and feelings, and if they choose to share them with a caregiver, confidentiality is an important factor in continuing a

### Nonpharmacological Management

- Prepare small portions of favorite foods.
- Allow child to eat “comfort” foods, don’t stress “balanced diet.”
- Use thickened liquids or soft foods.
- Offer shakes, smoothies, and other high-calorie foods.
- Provide nutritional drinks as tolerated.
- Assist family in limiting stress over child’s eating.

Neurological Symptoms

Restlessness/Agitation. Restlessness is a state of hyperarousal in which there is the sensation of not being able to rest or remain in a relaxed position. Agitation in children may present as irritability, combative ness, or refusal of attention or participation. Causes of restlessness and agitation in children with advanced disease can include a variety of physical and psychological causes (Table 49–7).

Assessment should include observing for such behaviors as frequent position changes, twitching, inability to concentrate on activities, inconsolability, disturbed sleep/wake cycles, and moaning. Spiritual distress, disturbing dreams or nightmares, fears, and comorbid anxiety or depression should also be assessed. Treatment for agitation and restlessness should use both age-appropriate pharmacological and nonpharmacological techniques (Table 49–8). Benzodiazepines may be helpful in

| Table 49–8 |
| Management of Agitation/Restlessness |
| **Intervention** | **Dose** | **Comments** |
| Pharmacological Management |
| Lorazepam | 0.03–0.1 mg IV/PO q4–6h, may titrate to max 2 mg/dose | Indicated for generalized anxiety |
| | | May increase sedation in combination with opioids |
| Midazolam | 0.025–0.05 mg/kg/dose IV/SQ | Titrable to effect |
| | 0.3–1 mg/kg (max 20 mg) PR | Indicated for myoclonus related to prolonged opioid use, mild sedation |
| | | Short-acting, quickly reversed if overly sedated |
| Haloperidol | 0.05–0.15 mg/kg/d PO, IV, SQ divided 2–3 times per d | Indicated for agitation not responsive to benzodiazepines |
| | | Monitor for extra-pyramidal symptoms, treat with diphenhydramine as needed |

Nonpharmacological Management
Maximize pain and other symptom assessment and management.
Decrease environmental stress or stimulation.
Encourage open communication between child and family.
Provide relaxation/guided imagery.
Provide favorite books, videos, or music.
Encourage cuddling or holding by parents and other significant family members.

Sources: Lacey et al. (2003), reference 29; Hellsten et al. (2000), reference 54.
reducing mild to moderate agitation and increasing effectiveness of nonpharmacological interventions.

In rare circumstances, children may experience such distressing restlessness or agitation as the result of unrelenting pain or other symptoms that the need for sedation may be considered. Sedation is generally indicated when distress cannot be controlled by any other means either due to limited timeframe or risk of excessive morbidity. Health care professionals must determine what are truly uncontrollable pain or symptoms versus undertreated pain and/or symptoms. Before considering sedation, it is important that all efforts have been made to achieve pain and symptom control. The goal of sedation is to relieve obvious suffering of the child by adding medications to induce sleep, but it is not intended to hasten death.

Presenting the option of sedation to a child and family requires a caring, open relationship between the treating health care professionals and the family. If the child and family are opposed to sedation, they should be reassured that all efforts to relieve distress will continue. If the child and family choose sedation, there are a number of pharmacological agents available to produce the desired level of relief. Consultation with a hospice physician would be appropriate to determine the clinical appropriateness and best agents to use to achieve the desired comfort goals of the child and family.21

Seizures. The risk for seizures in advanced and terminal disease is related to the nature of the underlying disease. Children with congenital malformations of the brain such as lissencephaly and congenital hydrocephaly, as well as other neurodegenerative diseases, often have seizures throughout their disease process. Children with malignancies of the central nervous system may experience seizures as an initial presentation of their illness or during disease progression. Children with advanced illnesses may also have seizure activity as a result of metabolic abnormalities, hypoxia, and neurotoxicity from medications. Seizure activity in children can present in a number of ways (Table 49–9). No matter what the cause, uncontrolled seizures are often one of the most distressing symptoms for parents. If a child has any risk for seizure activity at the end of life, emergency medications such as diazepam suppositories should be available in the home. Management involves correcting the underlying cause when possible and adding appropriate prophylactic pharmacological agents such as phenobarbital, clonazepam, or lorazepam (Table 49–10).

Dyspnea. The experience of dyspnea is one of the most common nonpain symptoms reported by children and parents.22–24,52,53 Dyspnea is the unpleasant sensation of breathlessness and can be particularly frightening for children. Diseases of childhood most associated with dyspnea include cystic fibrosis and other interstitial lung diseases, muscular dystrophy, spinal muscular atrophy, end-stage organ failure, and metastatic cancer. In each of these diseases, there can be a number of underlying causes (Table 49–11) that may be amenable to treatment.

The sensation of dyspnea is a subjective experience, and assessment should include the following: its effect on the child’s functional status, factors that worsen or improve dyspnea, assessment of lung sounds, presence of pain with breathing, and oxygenation status. Extent of disease, respiratory rate and oxygenation status may not always correlate with the degree of breathlessness experienced; therefore, patient report is the best indicator of the degree of distress. There is no validated tool to measure dyspnea, however, using a rating similar to a pain scale has proven anecdotally to provide some measure of distress and response to interventions.

Managing dyspnea is dependent on the suspected underlying cause of the symptom. Early in the terminal process, interventions for respiratory discomfort are aimed at improving respiratory effort. Antibiotics, oxygen, chemotherapy, or radiation to decrease tumor burden, and noninvasive ventilation for children with muscular degenerative disease, may be appropriate to treat the underlying cause. As the child becomes increasingly debilitated, the focus is on alleviating anxiety associated with respiratory changes and shortness of breath. There are a number of pharmacological choices for managing respiratory symptoms (Table 49–12). Opioids are the treatment of choice for managing dyspnea, as well as in treating a persistent cough. Anticholinergic medications assist in minimizing secretions. Bronchodilators promote increased air exchange in the lungs, and can be helpful alone or in conjunction with opioids. Anxiolytic drugs can help reduce anxiety related to the feeling of shortness of breath and improve respiratory comfort.54 As in other discussions of symptom management, it is important to determine with the child and family the level of intervention that is consistent with their perceptions of the child’s suffering and quality of life. For more information on dyspnea, see Chapter 13.

**Terminal Respirations.** In the final days to hours of life, respiratory patterns often change, initially becoming more rapid and shallow, then progressing to deep, slow respirations with periods of apnea, typically known as Cheyne-Stokes breathing. As the body weakens, pooling of secretions in the throat can lead to noisy respirations, sometimes referred to as “death rattle.” Often at this point in disease progression, children are somnolent most of the time and do not report distress. However, these symptoms are particularly agonizing for parents and other family members to experience. Assessment should include monitoring changes in heart rate and respiratory rate, observing for distress, stridor, wheezing, and rales/rhonchi. Management should focus on managing family distress by explaining the nature of the dying process, reassuring the family that the child is not suffering, administering appropriate anticholinergic medications to decrease secretions, and decreasing or discontinuing any fluids or enteral feedings that may exacerbate the development of secretions or fluid overload.

**Gastrointestinal Symptoms**

**Nausea/Vomiting.** The pathophysiology of nausea and vomiting is often multifactorial, can be acute, anticipatory or delayed, and requires careful assessment to determine underlying causes. Nausea and vomiting can cause extreme exhaustion and dehydration if not well controlled. Underlying causes of nausea and vomiting may include decreased gastric motility, constipation, obstruction, metabolic disturbances, medication side effects or toxicity, and increased intracranial pressure.

A detailed assessment of the onset and duration, as well as the presence of concomitant symptoms (e.g., headache, visual disturbances) must be obtained. Medical management of nausea and vomiting is based on the suspected underlying cause (Table 49–13).

Corticosteroids may be helpful in reducing an intestinal obstruction. Antiemetic medications combined with medications to reduce secretions (e.g., glycopyrrolate) can be helpful

in relieving nausea and vomiting related to intestinal obstruction. In cases of severe nausea and vomiting related to obstruction, placement of a nasogastric tube can decompress the stomach and provide comfort. Medications that promote gastric emptying (e.g., metoclopramide) or motility should not be used if obstruction is suspected. Steroids can provide relief from vomiting due to increased intracranial pressure. Nausea and vomiting related to medications or anorexia may be managed by a number of antiemetic medications. Relaxation techniques, deep breathing, distraction, and art therapies may assist in reducing anticipatory nausea. For more information on nausea and vomiting, see Chapter 9.

**Constipation.** Constipation is a frequent symptom experienced by children with advanced and terminal illness and can occur even in children with limited oral intake. Children and adolescents in particular become embarrassed if asked about bowel habits and will deny problems, leading to a severe problem. It is important to educate the child and family about the potential distress caused by constipation, and determine with the child how to discuss this issue. Constipation occurs due to inactivity, dehydration, electrolyte imbalance, bowel compression or invasion by tumor, nerve involvement, and/or medications. Symptoms include anorexia, nausea, vomiting, colicky abdominal pain, bloating, and fecal impaction. Physical exam may reveal abdominal distension, right lower-quadrant tenderness, and fecal masses. A rectal exam should be done; however, it is important to gain the child’s or adolescent’s trust before such an invasive assessment. Ask the child which parent he or she would prefer to be present and have that parent sit near the child and provide reassurance and comfort. Assess the rectum for hard impacted feces, an empty dilated rectum, or extrinsic compression of the rectum by a tumor, hemorrhoids, fissures, tears, or fistulas.

Management is aimed at preventing constipation from occurring, but if constipation has occurred, it should be treated immediately to avoid debilitating effects (Table 49–14). Stool softeners should be given for any child at risk of constipation due to opioid pain management or decreased activity. Softeners are most effective when children are well hydrated, so encourage the child to drink water as tolerated. Stimulant laxatives should be used if a child has not had a bowel movement for more than 3 days past that child’s usual pattern. If these measures are not successful, stronger cathartic laxatives (e.g., magnesium citrate) or an enema may be used. If there is stool in the rectum and the child is unable to pass it, digital disimpaction may be necessary. The child should be prepared for the procedure and premedicated with pain and anti-anxiety medications. For more information on constipation see Chapter 11.

**Diarrhea.** Although diarrhea is far less common than constipation in children with terminal illnesses, it still may occur and contribute to a diminished quality of life. Diarrhea may be caused by intermittent bowel obstruction, fecal impaction, medications, malabsorption, infections, history of abdominal or pelvic radiation, chemotherapy, inflammatory bowel disease, and foods with sorbitol and fructose (found frequently in juices, gum, and candy). Diseases related to increased risk of diarrhea include HIV/AIDS due to infections, cystic fibrosis related to malabsorption, and malignancies related to disease progression and treatment history.

Assessment should include onset, suddenness, duration and frequency of loose stools, incontinence, and character of the stools (color, odor, consistency, presence of mucus or blood), bowel sounds, presence of palpable masses or feces, abdominal tenderness, and examination of the rectal area. Assessment of dehydration includes observation of mucous membranes for dryness, cracking, poor skin turgor, and generalized fatigue. Diet and medication history should be reviewed for potential causes of diarrhea.

Treatment is aimed at managing the underlying causes and the results of persistent diarrhea (Table 49–15). Dietary intervention should involve continued feeding of the child’s regular diet as tolerated, as well as oral rehydration with electrolyte solutions as tolerated. For debilitated children using incontinence garments, attention to skin condition and prevention of breakdown is imperative. For more information on diarrhea, see Chapter 11.

**Summary**

Symptom management for children with advanced and terminal diseases presents a challenge to health care providers. Suffering from uncontrolled symptoms can be prevented by...

Pediatric Care: The Hospice Perspective

We sit outside at night and we talk about the stupid things people say, like “I know how you feel.” Which child of yours is dying of cancer or may die from cancer? If you don’t have a child dying from cancer, then you don’t know how I feel. You could have lost your husband or your wife or your parents, not your child that you gave birth to. It’s not the same game. You can get another husband. Can’t get another parent, but you expect your parents to go before you. You don’t expect your children to go before you.—Parent of a child with cancer

Perhaps a simple children’s book on the life cycle of nature, Lifetimes, illustrates it best: “There are lots of living things in our world. Each one has its own special lifetime. All around us, everywhere beginnings and endings are going on around us all the time. So, no matter how long they are, or how short, lifetimes are really all the same. They have beginnings and endings and there is living in between.”

Although much has been written about end-of-life care for adults, far less emphasis has been placed on the needs of dying infants and children. The ongoing painful dilemmas and struggles for families with infants and children who are dying remain hidden from society’s view, yet the demands and challenges of caring for a dying child are being addressed within hospitals and homes on a daily basis. Individuals committed to children with life-threatening illnesses and a modest number of hospice programs are making a difference, finding ways to significantly impact the imbalance in addressing the needs of children. The irony for pediatric caregivers is that “end-of-life care” is often necessary at the very beginning of a child’s life. Nurses can be instrumental in incorporating this contradiction into a realistic and compassionate framework for the care of children and families dealing with terminal illnesses. The report from the Institute of Medicine, When Children Die: Improving Palliative and End-of-Life Care of Children and Their Families, set forward the challenge to improve all aspects of end-of-life care for children and families, including improved quality and access to pediatric hospice. The National Consensus Project Guidelines for Quality Palliative Care published in 2004 also provide direction for pediatric care within the overall perspective of care for all those, adults or children, facing life-threatening illness.

The ultimate goal is not only to promote excellent end-of-life care for these children but also to elevate their status in a health care delivery model. Appropriate hospice care will bring them into the sunlight to be cherished among the living, where they will be removed from the isolating experiences of their dying. Improving quality of life for even a brief life can benefit the patient and all those affected by the death of a young child. Such a powerful wave goes beyond those most obviously affected—the parents and siblings. The rippling effect extends to grandparents, other relatives, teachers, school friends, family friends and neighbors, as well as the many health care professionals

• Key Points
• Nursing responsibilities in caring for the dying child are extensive.
• Specific education and training in symptom management and psychosocial issues are needed.
• Unique areas of concern when dealing with a pediatric population are the issues of the parents and those of the siblings.
• Improving quality of life for even a brief life can benefit not only the patient but all those affected by the death of a young child including grandparents, other relatives, teachers, school friends, and neighbors, as well as many health care professionals involved in their treatment and care.
• Nurses who choose to care for dying infants and children and their families need a significant support system themselves.
### Table 50–1 
**Children’s Hospice International Standards of Hospice Care for Children**

<table>
<thead>
<tr>
<th>Access to Care</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Principle</strong></td>
<td>Children with life-threatening, terminal illnesses and their families have special needs. Hospice services for children and their families offer developmentally appropriate palliative and supportive care to any child with a life-threatening condition in an appropriate setting. Children are admitted to hospice services without regard for diagnosis, gender, race, creed, handicap, age or ability to pay.</td>
</tr>
</tbody>
</table>
| **Standards**  | A.C.1. Hospice care services are accessible to children and their families in a setting that is desired and/or appropriate for their needs.  
A.C.2. The hospice team is available to provide continuity of care to children and their families in the home and/or in an institutional setting.  
A.C.3. The hospice program has eligibility admission criteria for the children and families they serve. Care plans are developed which take into consideration the child’s prognosis, and the child and family’s needs and desires for hospice services. Admission to the hospice care services does not preclude the child and family from treatment choices or hopeful, supportive therapies.  
A.C.4. The hospice program provides information to the community and referral sources about the services that are offered, who qualifies, and how services may be obtained and reimbursed. |

<table>
<thead>
<tr>
<th>Child and Family as a Unit of Care</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Principle</strong></td>
<td>Hospice programs provide family-centered care to enhance the quality of life for the child and family as defined by each child-and-family unit. It includes the child and family in the decision making process about services and treatment choices to the fullest degree that is possible and desired.</td>
</tr>
</tbody>
</table>
| **Standards**                     | C.F.U.1. The unit of care is the child and family. Hospice provides family-centered care. The family is defined as the relatives and/or other significant persons who provide physical, psychological, social and/or spiritual support for the child.  
C.F.U.2. The hospice program recognizes the unique, personal values and beliefs of all children and families. The hospice respects and maintains, as possible, the wishes and dignity of every child and his or her family.  
C.F.U.3. The hospice program encourages that children and their families participate in decisions regarding care, including discontinuation of hospice care at any time, and maintains documentation related to consent, advance directives, treatments, and alternative choices of care.  
C.F.U.4. The hospice program provides care that considers each child’s growth, development and stage of family life cycle. Children’s interests and needs are solicited and considered, but are not limited to those related to their illness and disability.  
C.F.U.5. The hospice team seeks to assist each child and family to enjoy life as they are able, and to continue in their customary life-style, functioning and roles as much as possible, especially helping the child to live as normal a life as is possible. |

<table>
<thead>
<tr>
<th>Policies and Procedures</th>
<th></th>

</thead>
<tbody>
<tr>
<td><strong>Principle</strong></td>
<td>The hospice program offers services that are accountable to and appropriate for the children and families it serves.</td>
</tr>
</tbody>
</table>
| **Standards**          | P.P.1. The hospice program establishes and maintains accurate and adequate policies and procedures to assure that the hospice is accountable to children, their families, and the communities they serve.  
P.P.2. The hospice program is in compliance with all local, state and federal laws and regulations which govern the appropriate delivery of hospice care services.  
P.P.3. The hospice program provides a clear and accessible grievance procedure to families outlining how to voice complaints or concerns about services and care without jeopardizing services. |

<table>
<thead>
<tr>
<th>Interdisciplinary Team Services</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Principle</strong></td>
<td>Seriously ill children with life-threatening conditions and/or facing terminal stages of an illness and their families have a variety of needs that require a collaborative and cooperative effort from practitioners of many disciplines, working together as an interdisciplinary team of qualified professionals and volunteers.</td>
</tr>
</tbody>
</table>
| **Standards**                 | I.T.1. The hospice program provides care to the child and family by utilizing a core interdisciplinary team which may include: the child, the family and/or significant others, physicians, nurses, social workers, clergy and volunteers.  
I.T.2. Representatives of other appropriate disciplines are involved in the team as needed, i.e., physical therapy, occupational therapy, speech therapy, nutritional consultation, art therapy, music therapy. The team might also include psychologists, child life specialists, teachers, recreation therapists, play therapists, home health aides, nursing assistants, and other specialists or services as needed.  
I.T.3. The hospice core team meets on a regular basis and an integrated plan of care is developed, implemented and maintained for every child and family. |

involved in their care and treatment. Each of these may also be deeply influenced by the child’s illness and subsequent death. Compared to a terminally ill adult, the comparatively larger number of people affected by a child’s illness or impending death is significant. Few, if any, have had any previous experience with the death of a child. Typically, multiple physicians, care providers, suppliers, school professionals, and a variety of family members are involved with these children. Each has unique needs and roles in the child’s experience. In addition, knowledge and skills regarding both palliative care and curative care are essential to guide families through this transition in the focus of care.5 Hospice care for children has not been well integrated into the existing national guidelines and regulatory standards. When this eventually takes place, the outcome will be a heightened visibility, credibility, and accountability for hospices, allowing home health programs and hospitals to adequately serve dying infants, children, and their families. The National Hospice and Palliative Care Organization (NHPCO) and Children’s Hospice International (CHI) trends reveal disheartening underutilization of hospice services for pediatric patients and related health care practitioners. The 1998 CHI survey reported that fewer than 1% of children needing hospice care receive it.6 Most state hospice organizations do not delineate which programs even serve children. The NHPCO revised its Hospice Standards of Practice in an effort to integrate pediatrics into those guidelines. CHI publishes Standards of Hospice Care. However, the standards are rarely put into practice at the predominantly adult patient organizations7 (Table 50–1). The result is an ongoing struggle for professional staff in pediatric care and for families, both of whom are dealing with end-of-life issues, unprepared for the journey they are embarking upon together. Calls for help and consultation come on a weekly basis to the author from health care professionals expressing concern and inadequacy regarding their ability to meet the demands and challenges of these young patients, their families, the schools to which they are connected, and the increasing complexity of their care.

Adult-focused programs and staff are typically unprepared to respond to the infrequent pediatric referrals, and also lack connections to pediatric providers to assist them in providing safe, appropriate hospice care. Treating children as small adults can be risky and is misguided for the patient, the family, and the staff.

The NHPCO developed four end-result patient/family outcomes that it requests hospice programs to use to measure their own effectiveness. These outcomes create goals on which all care and interventions should be based, thus creating opportunities for patients and families to achieve optimum care. The outcome measures are: (1) safe dying, (2) comfortable dying, (3) self-determined life closure, and (4) effective grieving.8 Although these outcome measures were not specifically intended for the hospice pediatric population, they remain highly relevant and are intended to apply to the patient and caregiving family. Hospice programs are encouraged to use these measures as the foundation for the philosophy and clinical practice behind their service delivery. For example, dying children frequently have specific goals and ideas about what would be important for self-determined life closure (e.g., reaching a milestone of completing a grade level, celebrating a holiday/birthday early, a desire regarding place of death expressed by child and/or parent). The many ways in which the child and parents desire to remain in control over several aspects of their lives can be woven into interventions so that each feels successful.

The Underutilization of Hospice for Infants and Children

A review of local (San Diego County, CA; Table 50–2) and national (United States; Table 50–3) death statistics illustrates the potential diagnoses considered appropriate for pediatric hospice care. Traditionally, cancer diagnoses have dominated the list of relevant diseases for hospice eligibility. Data related to the neonatal and infant (less than 1 year) age group were compelling. Causes of death in this category include prematurity, genetic/chromosomal anomalies, hydrocephaly, anencephaly, severe cardiac anomalies, cerebral palsy, gastrochisis, rare syndromes, and more, many of which were expected to be life-limiting in nature. Until recently, most pediatric patients served by hospices predominantly had cancer diagnoses, congenital anomalies, or acquired immunodeficiency syndrome (AIDS). National data, however, indicate other life-threatening diagnoses, including heart diseases, central nervous system disorders, degenerative disorders, mucopolysacchariduria, degenerative neuromuscular disorders, cystic fibrosis, liver and heart failure, and death-inducing trauma (e.g., drowning, motor vehicle accident, etc.).9

These less “traditional” patients include: children discontinued from ventilators following a motor vehicle accident or in the perinatal period who are not expected to survive; drowning accident victims who have not died immediately; chronically ill children with a progressive decline; babies who are “born dying,” i.e., transferred from a neonatal intensive care unit (NICU) to home or inpatient hospice care; children with rare and unusual syndromes; and those at any age for whom aggressive care has been withdrawn.

In addition to the above underserved pediatric patients, some circumstances also lead to other categories of underserved children, including those without insurance coverage for hospice care, those with an uncertain prognosis, chronically ill deteriorating children, children cared for by unprepared adult hospice staff, home health patients undertreated for holistic needs, and children of adult hospice patients (Table 50–4). Increased outreach to the health care specialists who work with these groups has resulted in increased referrals and utilization for consultation/collaboration. The development of the perinatal hospice component has created the opportunity for families to access hospice care during a pregnancy that is anticipated to have a fatal outcome for the baby at or soon after birth (Table 50–5).

On a positive note, progress is being made to address palliative care needs for children and families across settings, including
the emergency department, intensive care unit, and NICUs.
Extending hospice principles to these settings not only improves care while children are in those areas, but also may facilitate referrals to hospice from those settings. There is also tremendous opportunity to extend hospice and palliative care much earlier in the child’s illness, beginning at the time of diagnosis.

### Barriers to Accessing Hospice Care

Barriers to accessing hospice care for pediatric patients differ from those for adult. Society’s belief that “children shouldn’t die,” along with denial of the process, make end-of-life care for this population a distant and mysterious concept. Within the health care profession, a profound silence of discomfort and denial exists regarding babies and children dying. In some cases, health care professionals’ own attitudes and denial become the greatest barrier to their patients’/families’ ability to access additional options for expert palliative care and support services. In effect, this denies families the possibility of making an informed decision regarding the range of choices available during a child’s illness. Excellence in end-of-life care as part of the continuum of clinical expertise should be readily available for families who may transition or alternate their focus of care from a strictly curative mode to one of comfort and quality of life.

The original hospice demonstration project in the 1980s was designed as a Medicare program for older adults with cancer as

(continued)
the "typical" disease process. The constantly changing continuum of needs in the pediatric population, from birth through 21-plus years (including diagnoses, variable prognoses, developmental issues and needs, and varying family situations), has made it difficult to "fit into" the adult-oriented guidelines for admission and standards of care. These only increase the barriers to access to appropriate care for the dying child and his or her support system.

### Personal Issues and Biases

Nurses may experience emotional turmoil over their young patients’ declining conditions and poor prognoses. The professional role of the nurse may quickly give way to the perspective of a parent, mother, or father toward the child. Expressions of transference may emerge and become problematic to the parents, the child, the nurse, or other team members. In programs

*Data are based on death certificates.  
where nurses are not clinically trained or emotionally prepared to manage pediatric patients, many issues can emerge as a result of their anguish. Previous losses of a similar nature, unresolved grief issues, conflicting beliefs regarding “supportive care only” interventions, and insecurities and self-doubt are all common, even within the hospice setting. The “if it were my child” frame of thinking can even be imposed upon parents who are already desperately struggling with their child’s condition and the future that lies ahead for them. Personal and ethical dilemmas can emerge regarding withdrawal of aggressive care or nutritional support. Ethics consultations can bring an invaluable contribution to the decision-making process and often raise the option of a hospice consult or referral to hospice care.

Professional Issues

Nurses may lack pediatric physical assessment and symptom-management skills, as well as knowledge of the diverse disease processes and developmental stages and related needs essential to care for neonatal and pediatric patients. Those with a background in aggressive and curative care may find it difficult to support a family in transition to a palliative focus of care. A struggle for control may erupt between the family, the staff, and the child. By continually asking, “Whose need is this meeting?” one can maintain focus on the patient’s care.

Most nursing education programs include little or no emphasis on the care of dying children and their families, death and dying issues, grief and loss (professional and family), perinatal death, or hospice care. A recent study was conducted to determine the amount and types of content regarding pain and end-of-life care included in major nursing textbooks. Three of the 50 books reviewed were pediatric texts. Of those, only two had chapters on end-of-life care for this population. The findings revealed that textbooks had limited content regarding end-of-life care in general, with the pediatric subtopic an even smaller percentage. On a positive note, follow-up by the investigators of that textbook analysis also found that the pediatric texts have been responsive to these findings, making significant improvements in recent editions.

This deficit of information in academic texts explains why many nurses lack a foundation for care of pediatric patients at the end of life. In addition, there may be limited access to pediatric experienced staff of all disciplines to train or offer clinical support to the hospice staff. There also is a significant need to enhance the support provided to nurses working in pediatric hospice and in all pediatric settings caring for seriously ill children.

Uncertainty in Determining the Child’s Prognosis

State and federal regulations and standards governing hospice care and the clinical guidelines for ongoing appropriateness (Medicare and Medicaid) did not address pediatric patients when they were developed. Determining the required 6-months-or-less prognosis is extremely difficult for pediatric physicians because of the wide variability of prognoses in children, often varying from days to weeks, or months to years. Referral to hospice care by physicians also may represent to them “giving up” on their young patients. The requirement to certify that the child will be dead in 6 months is often perceived as a direct assault on the practice of physicians. Parents may still wish to continue active treatment, which may, in fact, prolong their child’s life to some extent, but typically are not ready to “give up everything.” Parents should not be forced to give up all treatment to avail themselves of help and guidance to actually make the transition to comfort care.

Payor or insurance providers may impose restrictions that deny access to hospice care for patients continuing curative treatment, and this is particularly problematic for children and parents. Parents and/or the child may want to pursue options that “buy more time,” even if the goal is clearly palliative care, in order to be together longer. These families are not just “waiting longer for death” but intentionally trying to maximize the “living time” they have left. The resiliency of children

</tbody>
</table>

is often astounding in the face of information that says they should have only hours or days to live. This has led to more pediatric hospice patients being discharged from the program. They have converted to a chronically ill child on a very different illness trajectory. These children are referred to as our “graduates” and the event is celebrated with the family. Adult programs are penalized for patients who do not die fast enough, and the pediatric population is even more difficult to predict. Frequent case review and discussions with parents, physicians, the hospice team, and, if possible, the child, ensure that everyone has the same goals and perceptions of the child’s condition and appropriateness of care.

**Reimbursement Issues**

The cost of caring for this population is often a barrier to pursuing a pediatric hospice program. Pediatric hospice care typically requires longer, more frequent home visits; more coordination of care with multiple physicians, other providers, and insurance companies; visits to schools by members of the team on behalf of the sick child or siblings; and hiring or access to pediatric experienced nurses, social workers, and aides. Ongoing therapies for palliation of distressing symptoms continues longer, typically, for children than adults, including blood transfusions, antibiotics, chemotherapy, and enteral and gavage feedings. The cost and responsibility for covering these therapies may be an additional factor to providers in deciding whether to serve children.

Insurance coverage may be inadequate or nonexistent for hospice services. Many states have waiver programs that provide nursing shift care in lieu of hospitalization or for respite care, but these programs also make the child and family ineligible to receive hospice care, creating an unacceptable conflict of needs. Many programs must raise additional funds to offset the expense of the staff-intensive support required for these families. The caseloads for staff managing this population typically are smaller than in adult hospice programs because of the increased time needed for coordination and care, especially if nurses do their own admissions. Traditional measures of productivity are impacted by these factors as well. The norms for practice with the neonatal and pediatric population stands apart from adult hospice care. Play and settling-in time are inherent to interactions with children, which starkly contrast with the direct care approach for adults.

**Lack of Knowledge and Awareness of What Hospice Care Is: Successful Strategies**

Physicians and nurses dealing with neonatal and pediatric patients may be completely unaware of the option of hospice/palliative care, how to access it, and the appropriate conditions or diseases for eligibility. In reality, pediatric programs are starting from the ground level, trying to educate and build bridges with “hospice-naïve” health care professionals to insure optimal end-of-life care for infants and children. For many clinical areas in pediatrics, death is an infrequent event; staff may not be particularly adept at managing the needs of dying children and their families due to lack of familiarity and experience. In intensive care settings, a change in focus to comfort care seems, for many, completely contradictory to their “culture of high-tech.”

Opportunities for families to receive hospice care begin when a relationship can be developed between a unit or department (e.g., NICU, pediatric ICU, hematology/oncology, labor and delivery, etc.) and the hospice team. Learning the needs and unique issues of each setting facilitates a customized approach to the specific populations served and the professional trust and accountability that are essential components for success. Discussing how to make referrals, adopting techniques for introducing the concept of hospice care to families and staff, exchanging expertise and resources, and providing in-service programs and educational opportunities are all methods to create a partnership between two specialties. This type of partnership can greatly influence the quality of life for patients, their families, and staff.

Participating in community based programs (e.g., Fetal Infant Mortality Review, perinatal nurse groups), coalitions regarding children’s health care issues, collaborations on grief and loss of children, and presenting cases at grand rounds and professional meetings are all excellent ways to connect with other providers and develop vital linkages for a thriving pediatric hospice program. Some clinical areas allow a hospice team member to attend patient conferences and rounds to provide input to the team as part of case reviews, or even to be an observer in identifying potential patients. Participating in the “informational only,” or evaluation visit with the child, parents, and staff can provide an excellent opportunity for modeling, learning the language of hospice care, and learning how to explain hospice services and roles. Trust is transferred between inpatient and hospice staff as a result of seeing, hearing, and experiencing what the other has to offer. The patients and families become more confident if they sense the confidence in those who make the referral. Many years of experience have revealed a higher level of expected accountability and responsiveness from pediatric caregivers regarding their patients when they are referred to hospice than for typical adult hospice care. Once trust and accountability have been established, they can form a strong and lasting foundation that can be passed on to new members as they join the hospice team. The need for ongoing, honest, and open communication between the two groups is critical.

**Myths About Hospice Care for Children**

Dispelling myths about hospice care can be helpful in creating an appropriate message about end-of-life or palliative care for pediatric patients. Many misconceptions need to be addressed, such as hospice care equals death; hospice care means giving up; hospice care means no more hope; hospice care means letting go or failure. It is important to clarify the scope and intent of hospice and palliative care and to address
false perceptions when developing any collaborative relationship. If health care professionals do not have a clear and factual understanding about what hospice care is and is not, they will pass incorrect perceptions on to each other and to families. In no other area of health care is it more important for parents to know what we do and do not do. They must be aware of the following:

- The team does not come in and force discussions on death and dying.
- The hospice team does not insist that families be in complete acceptance of the fact that their child’s condition is terminal.
- No one comes into their home and takes over or interferes with their sense of normalcy.
- The team does not decide what happens when.
- Team members do not get in between parents and their child.
- Team members do not challenge or judge the family’s belief system.
- Team members do not discipline the child or children, but only set reasonable limits with parental input.

Each of these issues should be discussed during interactions with patients and families. Parents are entitled to be told these things to dispel the unspoken or as yet unarticulated fears they may have concerning hospice care. The hospice team can make this difficult transition somewhat easier for parents by addressing what parents may fear the team might do with, for, or to their child or to them.

**Competition Between Home Health and Hospice Programs**

Terminal nursing care and pain management programs are incorrectly equated with the interdisciplinary, holistic approach to end-of-life care that hospice programs can provide. The collaborative model of the interdisciplinary hospice team weaves a stronger, broader safety net of support and care around the family, enhancing their ability to meet the extraordinary challenge of a life-threatening illness.

Agencies are challenged with the moral responsibility to make the right decision for the dying child and his or her family, informing them of all relevant options to best meet the needs of the child. It may be in the child’s best interest for a home care agency to refer the child to another, more appropriately qualified provider, such as a hospice program, if the program is better equipped to provide end-of-life care for the child. The multidimensional experience of a terminal illness requires attention to all aspects of the child’s, parents’, and siblings’ needs, including spiritual, physical, emotional, and psychosocial needs. An individual nurse may feel overwhelmed by the enormous burden of trying to meet all those needs alone or may experience intense frustration and helplessness in not being able to do so at all within the limitations of traditional home health care. Difficulties can also arise when a referral to hospice care is offered but refused by families based on unfamiliarity and perhaps dependency on the home health care nurse.

Possible solutions to this situation might be a joint case conference to discuss the family’s issues and concerns or making a few joint, overlapping visits to transfer trust and to ease the often well-established relationships to the hospice team. These may be nonreimbursed visits, but they may create an openness between the two programs and increase referrals. These visits may require discussions with the parents regarding their fears and concerns and how their needs might be met.

**Staffing Issues**

Many hospices are not staffed with nurses who are comfortable dealing with babies, young children, and adolescents who are dying, or with the unique issues of the parents and/or extended family. Because the family’s outlook is greatly influenced by the personalities and reactions of the staff, a special degree of confidence and caring is required. After-hours staffing poses a particular challenge, and sometimes a hardship, on the agency and its staff. Adult care staff may be unwilling or incapable of caring for pediatric patients. The most serious outcome would be added stress and uncertainty imposed by the very experts from whom families are seeking refuge and comfort. Partnering with pediatric staff to train other staff, as well as thorough reporting to the after-hours staff are helpful actions. Anticipation of needs and problems with a plan for appropriate treatment can minimize and even prevent symptom crises.

**Cultural Issues**

Various cultures approach the child with a terminal illness differently. This involves decision-making, communication, openness with the patient, the role of the parents in protecting the child from the truth about his or her condition, the role religion or faith plays in health care issues, and determination of who can translate for the family respectfully. Language barriers and lack of translation options can create great obstacles to providing adequate care. For example, parents may direct staff not to address the dying process with the child so as not to discourage the child. They may believe that in saying “it” aloud, it will cause “it” to come to pass. Or simply speaking of death may be too direct within the context of their culture. Hope is often intertwined in cultural issues and in the expression of that culture within the experience of serious illness. For some families, this may necessitate frequent and ongoing reteaching and subsequent validation that a plan for collaborative care has been respected. These issues of decision-making are of particular relevance to adolescents, as they play a more active role in decision-making regarding illness and end-of-life care.
Stretching the Boundaries of Hospice Care: A Model for a Comprehensive Program for Infants and Children

Since 1987, San Diego Hospice has been serving pediatric patients and striving to integrate pediatrics into the mainstream of the hospice culture and industry. What began as an informal relationship with a hospice staff nurse and the nurses and doctors at Children’s Hospital San Diego evolved into “the team,” a model for other programs across the country. Through many twists and turns, a vision emerged seeking to broaden the continuum of services for children at San Diego Hospice. The focus shifted from serving only a narrow target of sick and dying children to serving all children under the umbrella of care. This meant adding a component of specialized support and clinical intervention for the children of adult hospice patients (Figure 50–1 and Table 50–6).

Children Dealing With Adult Hospice Patients

Children’s Program social workers and, as appropriate, a chaplain, work directly with children who have a loved one, such as a parent, grandparent, aunt, or uncle, dying. Their interventions include opportunities for play and art therapy; rituals and keepsake activities for themselves or the family; therapeutic games; and storybooks on coping with feelings and illness, grief and loss, death and dying, the life cycle of nature, funerals, etc. For this new approach, the entire Children’s Program considers the focus of care not to be the “patient and family,” but the patient (adult or pediatric), family, and school.

The team extends the circle of care to involve the child’s or children’s school in its web of support for the family. Typically (with parental permission), the social worker will confer or even meet with the teacher, school counselor, or nurse to include them in the plan of care. The primary hospice team, focused on the adult patient, is kept abreast of their involvement and goals. The aim is to facilitate more involvement of the child in the illness experience before the death occurs, maximizing their support systems as well as their ability to cope with the death when it does occur. A great deal can be done to better prepare children for the death and loss of a loved one by early intervention. Besides anticipatory grieving, many practical issues, fears, and concerns emerge for the children and their caregivers. In addition, the team provides adult caregivers with strategies and education regarding children’s needs during the loved one’s illness and in bereavement.

The Child as a Hospice Patient

Families are never fully prepared for a child to be gone from their lives. The hospice professional can take steps to assist them down the long road of bereavement by helping them create tangible reminders of and treasures from their child’s life, no matter how short or long it is. San Diego Hospice has developed a lengthy profile of activities and rituals for families to consider performing while a child is sick. For example, families might create a memory box with the child of special
things that remind the child of favorite activities, trips, people, accomplishments—anything that helps to celebrate the child’s life. Letters and journals can also be created by parents, the sick child, and siblings and friends. The most popular activity with families is doing handprints. This is done by making handprints of the baby or child, along with parents, siblings, and others, using tempera or poster paint to create a unique family portrait. Ear prints can be taken of a baby with anomalies of the extremities and as another way of preserving something physical of the child. An “All About Me” booklet can be created over time through regular visits of a volunteer or family member, capturing the child’s identity before and after the illness and his or her role as part of a family. Schoolmates can send notebooks or letters back and forth to stay connected, and later these can become lovely remembrances of friendships.

The possibilities are endless, and these tangible keepsakes may help siblings and parents stay better connected to memories and significant events as they pass through developmental milestones over the years. These physical tokens may help relatives find their way back to special memories and events concerning their loved one. These treasures may help them to survive their experience a bit more whole, having a “toolbox” to help them integrate this tremendous loss into their being and may help them to create a sense of meaning about the experience over time.

These additional components were added to the Children’s Program to meet the needs identified by both the agency and community. The adult hospice patient referrals have been positively influenced by the availability of additional help, specifically for the children in the adult-patient families. The number of these children served by the Children’s Program continues to increase dramatically (see Table 50–6).

Local schools began to seek support, training, resources, and family intervention from this team. The next component added to the program became a commitment to assist and support the school community in confronting the illness, death, grief, and loss experiences of their students, families, faculty, and community members.

The first priority was to develop a staffing model for a mixed pediatric patient population. Hospice board and administrative support enhanced resources for handling a growing census and expanded focus. Critical to preserving the stability and integrity of the program was maintaining consistent staff focused on the needs of children, pediatric patient care, and program development. Requiring staff to work on both children and adult care on a constant basis had led to high staff turnover. While creating problems, these changes were essential to increase the visibility and credibility of the program within the community. These changes provided the optimal continuity of care desired by families, staff, and referral sources. It enhanced the ability of the program to meet the enormous demands of educating the hospice-naïve health care professionals throughout the community.

The Children’s Program next partnered with the local children’s hospital and health care center to become the hospice provider for their entire system. Adding a pediatrician as the children’s program medical director has been highly valuable. This role includes building physician relationships in various specialty areas, consulting on potential patients, physician education, identifying potential research, and enhancing clinical practice by hospice nurses.

Overview of Nursing Care Issues for Pediatric Hospice Care

Nursing responsibilities when caring for a dying infant or child are extensive. An awareness of “total suffering” requires that the nurse understand the interconnectedness of the four aspects of the experience of illness and suffering: physical, emotional/psychological, spiritual, and social. Each component greatly affects the others. In the words of Attig, “Suffering is the experience of brokenness. Illness unravels the pattern that belongs uniquely to each child, interrupting the ongoing stories of children’s lives.” Nurses must assess for imbalances and indications of suffering in each of these areas to appropriately intervene. Without physical comfort, a child has little energy to be “present” to those around him or her and engage in meaningful exchanges. Management of symptoms in children

requires the same degree of diligence and aggressive intervention as that used for adult patients.

Symptoms in children are generally similar to those in adults. However, discomfort/seizure management, pain in nonverbal patients, and feeding issues are more common. The age and developmental level of the child directly influence the selection of pain assessment tools, intervention strategies, route of medication, and type of medication. Many excellent resources are available to nurses for gaining competence in pain and symptom management for children. In addition, families require practical help, information, explanations, and support.用户的输入

Attention must be paid to the practical issues of preparing for pediatric-appropriate supplies, medications, formulas, feeding tubes, medical equipment, documentation, and teaching tools for parents and children. A gently written, parent-friendly handout on the signs and symptoms of approaching death is an invaluable tool.

Interaction with School

To provide education, support, and resources to classmates, teachers, and other parents, the team goes to the school of the sick child. The bridge developed between the hospice and schools has been a successful addition to the program. This came about in response to an ongoing need identified by the school community to support children during life’s challenging experiences.

For example, a child with astrocytoma was still attending school while having intermittent, recurrent seizures despite aggressive pharmacological intervention to control them. The hospice team and supervisor, parents, teachers, school administrator, school nurse, and classroom aide attended a conference at the school to create a plan to respond to her seizures. The need for proper documentation regarding her resuscitation status and hospice involvement had to be kept on hand and accessible in the event of a crisis, since the district was legally required to call 911 despite the parents’ wishes. Issues for the other students were addressed and recommendations were made. The emotional reactions of all involved were discussed, and support was offered.

Another example involved a severely disabled child who strongly desired to remain at school as long as possible. A similar conference was held, but with the child in attendance as well. A plan was made among all participants for the hospice staff to visit the patient at school occasionally. Again, a contingency plan was made in the event of an emergency so that the patient’s and parents’ wishes could be honored. In both situations, the schools were amazed at the collaborative effort and concern demonstrated by the hospice team. To them it seemed extraordinary. When the object of care is a child, a family, and a school, this is the expected standard of excellence.

Support for Siblings

Two unique areas of concern when dealing with a pediatric population are the issues of the parents and those of the siblings. Siblings require explanations along the way and opportunities to be included, not excluded, from these experiences that affect the entire family. Siblings relish the chance to be helpers to nurses and parents as a way to feel important and contribute to the tasks at hand. Helping serves to validate their relationship with the sick child, diminish their feelings of helplessness, and may well affect how they integrate the loss over time.

As mentioned earlier for the children of adult patients, in the same way for siblings, the goal for siblings of terminally ill children is to enhance their feelings of involvement to the greatest degree possible while the sibling is alive to facilitate a healthy grieving process. The attempt to assist in achieving “effective grieving” for the sibling must begin when the sick child is diagnosed, because the family is changed profoundly from that moment on.

Strategies for including siblings in care may be as simple as the nurse including the siblings in his or her visit, asking to see their rooms or favorite toys, or reading a story together. Joint visits with a social worker are highly effective in spreading the attention and interventions among the sick child, siblings, and parents. It is important to repeatedly evaluate the well child’s level of understanding about the sibling’s condition. Family meetings are also a good setting in which to discuss how everyone is doing, including the patient, how they each perceive the situation, how their needs are (or are not) being met, and how their fears and concerns can be addressed. With parents’ permission, an occasional small treat for the sibling is a simple gesture that may help make the well children feel special and included. Hospice volunteers make an excellent addition to the team for the specific role of being available to the sibling for a picnic, playing outside, reading, or a specific project or memory-making activity. Of these, the primary activity of the San Diego Hospice Children’s Team is handprinting with the whole family. The sick baby or child is handprinted and the rest of the family’s handprints are placed around the child’s. The activity lifts the family from focusing on the tasks of the illness to a playful yet reverent level. Subsequently, the print becomes a treasure for the family. The same activity can be done with children of a dying adult as a keepsake for the children. Siblings may wish to have their own set of prints as well. Parents and children are also given “memory boxes” to store treasures in.

Support for Parents

To counterbalance the overwhelming sense of powerlessness and helplessness parents frequently feel, nurses can help to identify ways in which they can feel more in control. For example, with ongoing preparation for anticipated changes in the child’s condition, a nurse can have medications in the home or instructions written for whom and when to call for assistance.

Typically, parents of dying children have two overriding concerns: a fear of a sudden or acute increase in pain that they will be unable to manage, especially as death approaches; and fear of a crisis situation or unexpected change in condition, including how and when death may occur. It is critical to address these issues on an ongoing basis.
The need to feel a sense of control is also relevant to the sick child, who may be fearful from experiencing so many physical and emotional changes. Nurses can assist parents with methods to help their child gain control over aspects of his or her experience, retain choices regarding care, and feel comfortable with a daily routine, all of which have great affirmational value. Managing medication regimens and symptoms is a daunting task for parents, having enormous impact on the family. Nurses should consider the overall responsibilities of parents for managing care as well as maintaining family routines when planning medication and treatment regimens with the physician.

Preserving Hope in the Midst of Serious Illness

A common characteristic of pediatric patients and their families is a prevailing sense of hope, evidenced in their language and decision-making. It is important to preserve and nurture hope during all stages of the child’s life-threatening illness. No matter how grim the situation, one should always strive to deal with matters in a positive yet realistic manner. The focus of hope inevitably must change over time, for example, from hope for cure, to hope for a longer remission than previously, to hope that the child can continue to be cared for at home, or to hope that the child will die without pain. Hope has a powerful and practical place within these families. With the presence of hope, parents speak of being able to continue their caregiving responsibilities, having the strength to put one foot in front of the other, and being able to carry on in their day-to-day existence. Without hope, the burden of the child’s impending death would be utterly paralyzing. Hope offers opportunities for growth for the child and family. Examples of a child’s hopes are a wish to return to school once more, to celebrate an important birthday, or to reach a significant milestone or rite of passage. Other expressions of hope include planning for a visit from grandparents, having friends gathered together, or even encouragement to consider going home with their baby to have the opportunity to “welcome baby home.” They may be offered a selection of “keepsake” activities to consider to preserve the presence of their little one’s life and record the connectedness they had for such a brief period. For them, it may be a simultaneous greeting and farewell. Strengthening this experience may help diminish long-term psychological implications for parents and siblings. Fortunately, much greater interest is developing in the intervention of palliative care in neonatal intensive care and other settings of infant care.

Hospice Care for Infants

When a dying child is an infant, the need for hope is similar, but time constraints are severe. Parents may need support and encouragement to consider going home with their baby to have the opportunity to “welcome baby home.” They may be offered a selection of “keepsake” activities to consider to preserve the presence of their little one’s life and record the connectedness they had for such a brief period. For them, it may be a simultaneous greeting and farewell. Strengthening this experience may help diminish long-term psychological implications for parents and siblings. Fortunately, much greater interest is developing in the intervention of palliative care in neonatal intensive care and other settings of infant care.

Baby Angel was born with trisomy 18 and not expected to live more than a few days at most. Upon that determination, the NICU social worker referred the family to San Diego Hospice. The team went to the hospital to meet with the young parents, who were weighed down with grief, their dreams and hopes shattered as the new reality for their baby was sinking in. The option of home hospice care seemed overwhelming while still adjusting to the news of their child’s impending demise. To ease the potential transition to home care, the parents and their infant were transferred to the Inpatient Hospice Care Center. Angel died within hours of her arrival, with her parents around her. The staff, unaccustomed to the needs of such parents, wondered why she was transferred at all. Was it inappropriate and a waste of effort? According to the parents, it was abundantly clear that it had been worth it and had allowed them to truly feel like parents in a peaceful environment. Compared to the crowded, public, hectic environment of the NICU, they felt peace in the hospice setting. They expressed tremendous gratitude for the efforts made on behalf of Angel’s brief life.

In another case, Baby Joseph was born with hypoplastic left ventricle and was, again, not expected to survive more than a few days. His parents were determined to take him home with them for whatever time they could manage and were eager to plan and fulfill this hope. The team worked quickly with the NICU team to arrange for his discharge and to be met at home by a pediatric hospice nurse and social worker. At home, they were admitted to the hospice program and settled in as family gathered to be with Joseph. Together, they created the opportunity to welcome Joseph into the family and into their home. Joseph kept them awake a lot with typical new baby needs. He died quietly in the early morning hours of the following day. Although to many it seemed tragic, his parents were grateful that they had been able to truly be parents for 1 day. In those hours, they were able to etch some precious yet ordinary memories like other parents have and experience the normal stresses as well as provide the comfort all babies need.

The implications for staff in caring for dying infants and children are enormous. Some are more suited for this field than others. Key personal attributes of those identified as successful in this role include a high tolerance for ambiguity and
flexibility; an appreciation for individual differences; good external support networks; a realistic awareness of personal limits; a joy for life in general; a sense of humor; an open communication style; a tendency to value self-awareness as an asset; empathy; and a willingness to learn continually. Being able to function in a self-directed mode facilitates using one’s own resourcefulness to meet the challenges of an ever-fluctuating schedule.

Perhaps the most basic necessary characteristic is a comfort with death. Only by coming to terms with one’s own thoughts and feelings about death is it possible to adapt philosophically to working with children who will die. Swanson-Kauffman developed a model of caring for nurses dealing with perinatal loss. She states that fundamental to caring is understanding the personal meanings of the loss; resonating emotionally with the mother’s feelings; offering realistic support, nurture, and protection; facilitating the expression of grief; and helping maintain her faith in her capacity to come through her loss a functioning, whole person. These also apply to the baby’s father.

Perinatal Hospice: The Early Intervention Program

In response to a need identified by parents, an innovative addition to the Children’s Program was developed as an extension of existing hospice care. This new program grew out of the existing newborns with limited life expectancy described as “babies born dying.”

Mothers and parents were coming directly to the hospice for help out of desperation, facing a prenatal diagnosis of a devastating nature for their unborn baby. These parents had decided to continue the pregnancy and treasure their child’s life for as long as they could, yet they lacked any ongoing support. Their message was clear: “Finally, someone will just accept our decision and help our family deal with this experience. We don’t want to just sit back and wait for our baby’s death.” Hospice professionals are trained to use an individualized approach to assist patients and families in dealing with life-threatening illnesses and their decisions concerning that experience. This unique group of parents faced the daunting challenge of anticipating and preparing for the birth and death of their baby simultaneously. What they are given, with the help of this unique program, is the opportunity to feel some level of control by making plans based on their individual needs for supporting themselves, their other children, the grandparents, and friends.

The Early Intervention Program provides support to expectant parents through counseling and spiritual guidance for the entirety of the pregnancy, starting prior to and continuing after the delivery. Parents are advised of ways to create a personalized birthing plan that addresses their wishes for themselves and the care of their baby once born. The plan may include specific instructions and preferences for the labor and delivery staff, such as keepsakes and rituals they may wish to create or perform. Some parents await a definitive diagnosis after the baby is born to decide the extent of care to be provided.

The parents’ goals and plans are discussed in collaboration with their physician. The physician is kept up to date regarding their psychological state and the development of their birthing plan. Prenatal nursing care is not a part of this program. These women continue their prenatal care under their physician’s guidance. The pediatric hospice nurse is involved in educating the parents on the diagnosis, helping them understand what to expect, planning for the possibility of home care, and helping siblings understand the baby’s condition.

Perhaps as a reaction to the lack of responsiveness by the health care system and society in general toward perinatal loss, these parents have found ways to support each other. They have truly disenfranchised grief, one not recognized as equal to the grief experienced with other types of death. The Internet is rich with amazing and profoundly intimate resources and ideas, shared experiences, practical help, opportunities to gain support, and even memorials to lost children. These parents have discovered help from within their isolation from others like themselves. Hospice professionals can gain valuable insight from their perspectives and excellent ideas on ways to improve support for these parents.

Initial feedback from the hospice bereavement counselors who work with these parents has highlighted the potential and anticipated impact of the perinatal hospice service. The bereaved parents who received help through the Early Intervention Program demonstrated the following: they were more emotionally and spiritually prepared for their infant’s death; they experienced less intense despair/sadness; they had better marital relationship communication and support; and they felt fewer “raw” intense emotions such as anger, rage, and uncertainty regarding the cause of death. The parents without hospice care during pregnancy and after birth seemed to demonstrate a more intense grieving experience, whereas the others expressed a sense of gratitude and peace surrounding the brief life of their child. Parents have told us that they are able to be fully present for their baby when he/she is born due to the planning and guidance beforehand. It also allowed them to maximize the limited time to truly celebrate and to welcome the baby before they had to say goodbye—an essential ingredient to their healing process.

Over time, the keepsakes accumulated during the pregnancy and birth—photographs and other objects—can assist young siblings and parents to integrate the loss of the child into their family experience. Before delivery, a family picture can be taken with the family gathered closely around the mother, all hands placed gently on her abdomen. Because the baby may die in utero or at birth, this earlier image may be helpful in recording and preserving his or her presence in their lives. The team provides paint, poster board, and a memory box, then assists in obtaining handprints of the baby as well as of the entire family at the hospital to create another “family portrait.” Because almost all NICUs and labor/delivery areas have developed procedures and activities for the experience of infant death, the hospice team works with the
inpatient staff as a bridge of continuity in the parents’ experience. Planning the “who, what, when, and where” for the delivery and beyond is important. If this information is not shared with the hospital staff, time may be lost and opportunities missed forever for some critical experiences for the family.

Making both the pregnancy and the death more real helps reduce denial of the loss. Mourning the dead child is facilitated by visual reminders over which families can grieve.30 The social worker can provide parents with ideas for memorial services or assistance with final arrangements. The chaplain can assist them in personalizing these arrangements, helping to create the theme that reflects their beliefs and desires, and even helping to facilitate their wishes. Even a brief life is mourned for a very long time. Seeds for more effective grieving may be planted for the long journey ahead to recovery and healing.

Acculturating an Agency to a Program to Serve Children

Integrating the Children’s Program into the culture and values of San Diego Hospice is a goal in progress. Similarly, efforts continue on a national level to integrate pediatrics into the NHPCO’s infrastructure and scope. Internal education and ongoing discussions were the first steps toward creating awareness of the service needs related to this unique population. Just as hospices initially had to confront issues of discomfort, fear, and personal barriers when caring for AIDS patients, the same must be done regarding pediatric patients. Admitting dying infants and children into programs poses an equally challenging situation for both clinical and nonclinical staff. The challenge is to normalize children as part of who is served by hospice care providers. As an industry, hospice and palliative care must commit to serving dying patients across the entire lifespan so that all families may receive this help as they face end-of-life care. Only then will it become integrated into more individual programs.

Ongoing efforts are needed for addressing the ethical issues related to removing life support, discontinuing aggressive care with a dying child, maintaining confidentiality, and incorporating the child’s or sibling’s school into the plan of care. Prospective hospice employees, both clinical and nonclinical, are informed that infants, children, and young parents are part of the continuum of care. A detailed description of pediatric hospice care during staff interviews and hiring constitutes “informed consent” that the prospective employee acknowledges that these issues will be encountered within the agency. From the education committee to new-hire orientation, and from the ethics committee to business development and marketing, the message is reiterated that children are part of the organizational mission and service population in a variety of ways. If left as the responsibility solely of the Children’s Program staff, the potential may be diminished to truly foster an emphasis on children’s issues in agency philosophy and practice.

Perhaps with this model as an example, other hospice programs and providers will examine how they might better address the needs of children and enhance their capacity to integrate the very young into their existing services. There is much to be done to support these families and advance the quality of end-of-life care for infants and children. Each step toward increasing awareness regarding these issues is a step forward on behalf of the children who are dying without access to all the resources available to them and their loved ones.

Nurses who choose to care for dying infants and children and their families need a significant support system themselves to maintain the difficult and delicate task of balancing perspectives. However, in doing so, nurses receive a spiritual treasure that only comes from experience with these children, parents, siblings, and others around them—heightened awareness of how very precious life is. Families share their wisdom from their tragedy, urging others to make the most of each moment in their own lives with their own loved ones. The courage and strength observed in families on this pilgrimage is humbling and strengthening at once. The staff of the Children’s Program cherish and are grateful for the opportunity to be eyewitnesses to one of life’s most intimate and powerful experiences.

Attempts to enhance end-of-life care for infants and children are gaining momentum, as evidenced by recent efforts to create a demonstration project with the Health Care Finance Administration, CHI, and NHPCO. Their effort aims to redesign the model of hospice care to more appropriately meet the needs of young patients and families. It will allow hospices to care for them through a model that begins at diagnosis of a terminal condition and continues through bereavement for the family. Through a collaborative effort with leaders in hospice care, pediatric hospice care, children’s health care, and various branches of government, plans are moving forward for appropriations and site applications for the demonstration project. The Children’s International Project on Palliative/Hospice Services (ChIPPS) is an international work group that represents the work of experts and leaders in the field of pediatric hospice care. The group is developing a variety of research plans and identifying “best practice” examples and models of care for a compendium of resources to assist hospice programs more quickly to develop services for infants and children.

Hospice care for infants, children, and those around them focuses on living as fully and as normally as possible within the context, limitations, and opportunities that come with life-threatening illnesses.31,32 It seeks to provide children and their families with the means and opportunities to achieve self-directed life closure in a manner that they themselves define. Pediatric hospice care aims to raise the consciousness of our society that claims to value children as a treasured resource. If this is so, then we must treasure them and honor them in sickness and in health, in living and dying, until death do they part from us.

Pediatric Care: Transitioning Goals of Care in the Emergency Department, Intensive Care Unit, and In Between

We are in need of medicine with a heart . . . The endless physical, emotional, and financial burdens that a family carries when their child dies . . . makes you completely incapable of dealing with incompetence and insensitivity.—Salvador Avila, 2001

Every word that was said the day Becky died is indelibly etched in my mind. I have replayed the words in my mind a million times. It’s a never-ending tape.—Pam Borchart

Palliative care is comprehensive, interdisciplinary care focused primarily on promoting quality of life for patients and families living with a life-threatening illness.2 It can and should occur from the earliest recognition of a life-threatening condition and can be concurrent with efforts to prolong life.1,3 Palliative care is as applicable in the ED and in the ICU setting as it is in the home.4–6 This is a critically important issue for children who die, since the vast majority of childhood deaths occur in an ICU setting. In fact, Wanzer and colleagues7 state:

As sickness progresses toward death, measures to minimize suffering should be intensified. Dying patients may require palliative care of an intensity that rivals that of curative efforts. Even though aggressive curative techniques are no longer indicated, professionals and families are still called on to use intensive measures—extreme responsibility, extraordinary sensitivity, and heroic compassion.

Approximately 50,000 children die annually in the United States.8 Infants (<1 year of age) die primarily of congenital defects and prematurity; however, sudden infant death syndrome (SIDS) and trauma (including accidents and homicide) account for 12% of infant deaths. For children (age 1 year–24 years), 72% of deaths are the result of trauma, while the remaining 28% are due primarily to cancer, congenital anomalies, and heart disease. Trauma occurs in previously healthy children who are suddenly injured, and, in most cases, for whom resuscitative measures are initially called for. In addition, some previously healthy children become suddenly ill from an overwhelming illness, such as a viral cardiomyopathy. Thus, the vast majority of children who die are appropriately cared for, at least initially, in the ED and ICU settings. Most children who die of these conditions currently die in the ED or ICU as well. Even children with chronic illnesses and anticipated deaths often die in the ICU, though this may be due less to need or preferability than to the lack of alternatives.

+ Key Points
+ Pediatric palliative care often occurs in the intensive care unit (ICU) and the emergency department (ED), unlike adult palliative care.
+ Compassionate, effective, and consistent anticipatory communication with the family and the patient is critical to appropriate planning and to the prevention of suffering.
+ Attention must be paid to the child’s and family’s perspectives and goals.
+ Parents’ roles are severely challenged by the illness and potential death of the child, rendering decision-making much more difficult.
+ Meticulous assessment of and relief of symptoms is critical to engender confidence and to prevent unnecessary suffering; pediatric-specific tools and protocols must be used.
+ Grief and loss of the child on the part of the parents, family, and health care personnel must be addressed.

or effective family counseling and advance planning. In fact, 4.6% of pediatric ICU admissions end in death.6,11 However, few ICUs or EDs are places that one would choose to die. Most children and adults, when asked, prefer to die at home.12,13 ICUs and EDs are not “homey.”

There are a lot of rules that keep the ED and ICU safe and efficient; these same rules may interfere with simultaneous visits from extended family and friends as a child’s life draws to a close. ICUs and EDs are in the business of saving lives; scrupulous attention to communication, symptom control, and grief management have not been a traditional focus of training for health care delivery or personnel.14 Yet, children and neonates will continue to die in ICUs and EDs.15 There are ways to meet these patients’ and their families’ needs for a peaceful, family-centered death, even in these circumstances.6,16 Specific suggestions for care in the ED have recently been published.17,18

While individuals and families differ in the details and nuances of what their conception of a good death is, common themes emerge. Just as with adults, chronically ill children’s biggest fears are abandonment by their medical caregivers and families.19 It is often observed that children will endure treatments they no longer value to protect and not disappoint their parents and doctors. However, children also have needs and priorities in their final days and months that are determined to a large extent by their developmental maturity. For infants, this includes the physical presence of their family. The smell and feel of familiar people provide essential comfort. For toddlers, routines and familiar people and objects assume great importance; for older children, it is social contacts; and for teens, the ideals of having left a legacy and having peer support are critical. The common ICU policy of limiting visitation can interfere with these aspects of achieving a “good death.”

Most children and their families want as much honest information regarding prognosis, clearly and empathically communicated, as they can get, beginning as early as possible in the course of illness, followed by regular updates as the prognosis changes.20–22 This allows rational decisions to be made based on the facts and on the values of the child and his or her family. Patients and families need to understand the anticipated disease trajectory and its associated symptoms and feel confident that they can manage them. They need to understand realistic options for medical care goals and the projected benefits and burdens of each option. Parents need to feel that they have done everything that is “appropriate”; that they have been good, brave, and loving parents; and that the child has “been a fighter.”

It was terribly important for us to do exactly what was right and necessary to help our daughter . . . Our nurse and social worker made us feel that we WERE, in fact, doing everything in our power to take care of our daughter.—Kathleen and James Bula, parents1

They need to know what care venues are available to them and how to access them to avoid recurrent, nonbeneficial ICU admissions in the setting of chronic illness. Children with terminal conditions and their families often want spiritual consultation and guidance since it is very hard to understand why so tragic a thing as a child’s death has to occur. Above all, children and their families want to feel valued as individuals, with the awesomeness of the impending death duly noted and the opportunity for closure and growth at the end of life to be realized to the greatest extent possible.19,23–25 If end-of-life care is properly provided, more children with chronic, life-threatening conditions will have the opportunity to die outside the ICU; in a setting they or their family prefer. Avoidable ICU deaths are taxing to the patient and family as well as to the ICU personnel, who often begin to ask, “Are we doing this to the child or for the child?”

Nevertheless, since a large proportion of children who die do so of acute conditions in the ICU, consideration of palliative care issues must be a part of the care plan.26–27 This chapter delineates the topics to be considered, explicates concrete suggestions for implementation, and provides case examples in a university hospital system that has instituted some of these strategies in the care of infants and children.

Communication

Clear, honest, open communication is as critical a factor in the care of terminally ill infants and children as any other factor.28 It may be even more significant because of the sensitivity required to assess the cognitive development of young patients. Some of the factors involved in achieving good communication during the terminal illnesses of children are covered in the following sections.

Preparation and Adherence to Advance Directives

Families and children need and usually want honest information to assist in making good decisions regarding the goals of medical care. Children have a right to be offered information about their treatment options and the associated benefits and burdens.7,28–32 This information must be presented in a manner consistent with the child’s developmental capacity.28 Ideally, a patient with a chronic, progressive, and ultimately fatal illness would be provided information gradually and recurrently, in an outpatient setting, tailored to the child’s particular condition and the family’s value system, orchestrated by a long-standing primary care physician.34–37

A suggested format for initiating the discussion of advance care planning appears below:

I would like to take a few minutes to talk about some decisions about treatment for Maia that may come up in the future. As you know, it is possible that Maia’s condition will get worse and that she may die. We are doing all we can to prevent that, but if that time comes, you and Maia may want to change the way she receives
care. [Pause for response.] For instance, you may want to avoid a lot of procedures and time in the hospital, and you may choose to take her home and receive help to make her comfortable there. Maybe you are ready to talk about these kinds of things today, but it may take some time before you’re ready. [Pause for response.] That’s okay. I just want to let you know that I’m ready to talk about those kinds of things whenever you feel ready.

Other families have told me that it can be very difficult to think and talk about decisions related to dying when they’re still hoping for a cure. But the families whose children have died tell me that, when the time came, they were very glad they had considered and talked about those decisions beforehand. We can start talking now about the issues that may come up if your child’s condition gets worse, but we don’t have to make any of the decisions right now. You can think about it all, talk with your family, friends, spiritual adviser, family doctor, or whomever else you want. Then we can make the decisions bit by bit, as we go along.

As we go along, it’s really important that you ask whatever questions you have on your mind, even if you think they might be obvious or very difficult to ask. Just to give you an example, some parents who are thinking about taking their child home for care at the end of life want to know who are they supposed to call at the time of death. It’s very difficult for them to ask about that but it’s very important information for them to know. So whenever you have questions, about anything, please just ask. We will do our best to answer them.38

Most state advance directive laws do not specifically mention children. However, while there is no mandate to address the issues of prognosis or future anticipateable medical interventions and their expected benefits and burdens for chronically ill children, the intent of advance directives applies equally to children with decision-making capacity as it does to adults.

Unfortunately, even when advance directives have been thoughtfully crafted and executed, there are rarely mechanisms in place to honor these decisions. In addition, parents may feel too guilty and too unprepared to follow through with their decisions to limit medical intervention. All too often, when the child begins to have the predicted deterioration, symptoms are inadequately controlled because no palliative care plan is in place and the patient appears in the emergency room in extremis.

On arrival at the emergency room, the family is often asked: “Do you want us to do ‘everything’?” “Everything” and its possible outcome is not further explained, so there is no reasonable answer but “Yes!” However, to the child and his or her family, “everything” may mean everything to make the child comfortable, whereas to the physician it may mean everything to prolong survival, regardless of the extent of suffering. Assumptions should not be made; clarification of ambiguous terms must be accomplished to ensure that the care rendered is the care desired.38

In addition, if the child’s symptoms are aggressively controlled in the ER, more rational decision-making can take place. The family could, for example, choose to have the child intubated for respiratory distress or to accept comfort management outside the ICU if extended survival is unduly burdensome for the child as an individual. Moreover, many families harbor significant misconceptions regarding the outcomes of life-sustaining treatments.

A child with long-standing persistent vegetative state, seizures, and gastroesophageal reflux (despite a fundoplication and two antireflux medications) came to the PICU with his fourth full cardiac arrest that year, as a result of yet another aspiration episode. He was admitted through the ED and brought to the PICU on a ventilator, with pressor agents being infused. When his caregiving grandparents were asked about what they hoped we could accomplish with our medical care, they replied, “We want him to be better.” When prompted to further clarify their expectations, they replied, “We want him to be like his brothers; to walk, talk, and go to school.” Once informed that this was, unfortunately, not possible, they revised the goals of care, dramatically changing the care plan.

In particular, the misperceptions of a high likelihood of survival following CPR and the lack of awareness of the potential to develop significant disability after cardiac arrest have been documented.39,40 The impact of accurate information on the increased likelihood to forgo CPR has also been proven.41,42 Children have a particularly poor outcome from true cardiac arrest.43–47 In the absence of intoxication and congenital heart disease, primary cardiac causes of arrest are exceedingly rare. Children have very healthy hearts. Thus, if cardiac arrest has occurred, it indicates that there is severe multi-organ dysfunction or that there has been a prolonged hypoxemia; neither of these underlying causes of arrest are amenable to medical treatment. Resuscitation in these settings does not commonly lead to intact survival. However, this is not the message that families understand when they are asked, “Do you want us to restart his heart?”

Similarly, seemingly benign comments, such as “He is stable,” can be misinterpreted by families of dying children to mean “He is going to be all right.” “She has gained weight” may mean the child’s condition is worsening if the infant has heart failure, but is universally interpreted as good news by parents of infants. It is critical that members of the health care team communicate effectively with each other and that they give clear and consistent messages to the family.43 Participation of the bedside nurse in daily rounds and in family meetings makes this process smoother. The information that nurses gather from patients and parents at the bedside is critically important to the entire team in understanding what the

It is important to realize that the role of parents as protectors is threatened by the possibility of the death of their child; this occasionally renders them unable to acknowledge or to notice the suffering involved in the ongoing attempts to prolong life. For this reason, whenever possible, the knowing child (who may be as young as 3 years if he or she has been chronically ill) should have a voice in the discussion of the goals of medical intervention. In addition, the issues of parental guilt (“I can’t let my child go—it would mean I failed as a parent.”) and family suffering should be frankly discussed. In the author’s experience, reassuring parents that letting go is a loving decision has been helpful.

When discussing the choice to forgo life-sustaining medical intervention, the topic of current burdens of therapy as well as the probability of the hoped-for benefits must be clearly explained. Suggested ways of approaching these issues with parents, can be found in Table 51–1.

Nurses, who are often the most trusted member among the caregiving team and who have the longest exposure to parents in the inpatient setting, are in an excellent position to ask many of these questions. Ineffective therapies must not be offered. Common misperceptions about the effectiveness of CPR must be proactively addressed. The proposal to forgo further attempts to prolong life should be presented as a recommendation, not a choice for the family to make alone. The benefits of stopping life-sustaining treatments can be presented as the benefit of dying at home, where possible, or, more commonly, increasing the chances of dying in the hospital at a time when the family is all there together to support the child and each other instead of at some unpredictable time in the middle of the night with no one around. Presenting the option inaccurately as “stopping care” is, not surprisingly, usually rejected. This short-hand phraseology is perceived as painful and unloving. Patients and families fear abandonment above all else. A more accurate description is to recommend stopping ineffective interventions, stopping unduly burdensome treatments, changing the goals of care to better meet the needs of the patient in the face of having proven that life-prolonging measures are failing to work. One of the most damaging sentences uttered in the context of irreversible illness is “There is nothing more that we can do.” Above all, it is patently untrue. Despite our inability to cure or prolong life at all times, we always have something to offer, even if it is only ourselves. Most important are the promises to care; to aggressively control symptoms; to be available; to assist (as a multidisciplinary team) in the arrangement of visits of family and friends; to facilitate the observation of important rituals; to provide spiritual guidance (when desired); and to transfer to alternate settings (according to the patient’s and family’s wishes). One suggested phrase that captures the essence of intensified caring with new goals is: “We will help your child live to his fullest to the very last moment, regardless of when that is. His comfort and yours are our top priority.” The family may also need assistance with funeral arrangements and will benefit from bereavement follow-up provided by direct caregivers.

### Table 51–1
**Helping Families with Difficult Decisions**

| • Please tell me in your own words what you understand about your child’s condition. |
| • Please tell me in your own words what you understand about the care being provided to your child at the moment. |
| • What things have you found particularly difficult to deal with during your child’s illness? Who or what has helped you through them? What kinds of additional help do you need, if any? |
| • How have you been involved in decision-making about your child’s care up to this point? How have you felt about that involvement? How would you like to be involved? |
| • How have other members of your family (for example, your child’s siblings or grandparents) been involved in discussions and decision-making up to this point? |
| • What are your wishes about the care being provided to your child? |
| • If we were looking at a time when your child may not be able to get through the illness, can you tell me some of your wishes about that time? How would you like things to be? |
| • Do you have any particular worries about the time when your child may not be able to live through this illness? |
| • What are your fears or concerns about what your child is experiencing now? In the future? |
| • What are the most difficult things you are facing at this time? What do you think you might need to help you get through this time? |
| • What are your fears or concerns about what your child may experience if he or she is unable to live through this illness? |
| • Is there something that I could do, or avoid doing, to better help you and your family through this time? |
| • Is there something you can think of that would best help your child through this time? |

### Time-Limited Trials

Once the child is in the ICU receiving life-sustaining care, it is helpful to review the patient’s progress continuously, monitoring the “big picture” of whether the patient is progressing along the hoped-for trajectory of illness or whether he or she is deteriorating despite the best medical management. Daily updates of this clinical information provided to the patient (when possible and appropriate) and the family can facilitate reasonable decision-making, thereby avoiding burdensome and unhelpful care and diminishing the element of surprise on the day the
patient dies. Letting the parents know when the child should reasonably be expected to show a response to treatment and agreement to meet again at that time to discuss how it is going is an effective tool and provides a timeframe for the family to gather their supporters for the news, good or bad.

### Breaking Bad News: The Nurse’s Role

While breaking bad news is difficult and stressful for everyone, being uninformed is even more stressful for patients and families. One of the most common complaints of patients and

<p>| Table 51–2 |</p>
<table>
<thead>
<tr>
<th>Breaking Bad News</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Provide a “warning shot” or an introductory sentence before presenting the distressing information: “I am sorry that I have some bad news to tell you.”</td>
</tr>
<tr>
<td>2. Provide an opportunity for supportive friends or family to be present when the information is shared: “Would you like to call someone to be with you when we talk?”</td>
</tr>
<tr>
<td>3. Tell the news in a private setting, with the physician, nurse, and social worker present. Bring the family (generally parents without the child first, depending on relationships and preferences) to a private conference room rather than speaking to them in the waiting room or the hall. Bring tissues. If appropriate and desired by the family, assist them in telling their children (patient and siblings) afterwards.</td>
</tr>
<tr>
<td>4. Sit down near the family, not across a table. Do not stand. Children and families want to be on an even plane with their caregivers. Look the family members in the eye to engender trust unless this is culturally undesirable. Ask them to tell you about their child and about any consistent values of the child and about the things that give him or her pleasure. Ask how much they want to know about his or her medical condition and prognosis. Ask them what they understand is happening. Clarify misconceptions, particularly about the cause of the problem, and attempt to assuage any guilt that may derive from having an inherited or developmental problem (“You did not wish for your child to have this”) or from trauma or other causes. Then, let them know this news is difficult for you as well. Nurses can help guide the physician to present the truth in a jargon-free manner that is consistent with the family’s educational level, sophistication, and stated desire for knowledge. Ask the family to explain what they understood was said. Clarify misconceptions. Then, solicit additional questions.</td>
</tr>
<tr>
<td>5. Be unhurried. If there is only a limited time available for the physician, let the family know: “I’m sorry the doctor only has 15 minutes now, but I will stay with you and answer any questions I can, and the doctor will be back later this afternoon to answer anything I can’t and to update you.” Don’t look at your watch. Have the charge nurse or another nurse care for your patients while you sit with the family. Remind the other team members to give their beepers to someone else during the family meeting, when possible; otherwise, switch the beepers to vibrate mode.</td>
</tr>
<tr>
<td>6. Ideally, members of the multidisciplinary team participate as full members during the family conference. The bedside nurse, chaplain, and social worker benefit from hearing the physician–family interaction. They can solicit questions, clarify misconceptions during the meeting and after the physician leaves, and address other facets of the patient’s situation that the conversation with the physician evokes. Team members can also give the physician feedback regarding his or her communication with the patient and family, such as words they did not understand, and can help the physician address any unresolved issues at the next meeting. This technique requires interdisciplinary respect and cooperation, which are essential to successful, comprehensive end-of-life care; it prevents divisive misunderstandings between disciplines regarding suspected coercion or other undesirable communication.</td>
</tr>
<tr>
<td>7. Bring trainees to the family meeting. This allows the assigned nursing or medical student and resident to learn from directly observing the interdisciplinary critical care team, as well as the patient and family responses. It keeps trainees informed so that unnecessary and often damaging miscommunications do not occur. Trainees often get lost in the minutiae of the patient’s laboratory values and vital signs and may unwittingly provide contradictory information to the family. However, do not overwhelm the family with white coats—have trainees take turns attending family meetings.</td>
</tr>
</tbody>
</table>
| 8. Be specific. The physician should present the options, include a description of life-sustaining treatments, the child’s current status, the chance of survival, the probability of full recovery (and the probability of significant disability), and the possible effects of the child’s long-term survival on the family.
families is the lack of accurate and clearly communicated information.20–22,26,57–64 Accompanying comments indicate a willingness and desire to receive bad news as long as it is empathically communicated. The diagnosis and prognosis associated with chronic conditions often provide confirmation of what was already suspected, thus frequently resulting in relief and reduction of anxiety. Reactions to bad news in the setting of an acute event are much more dramatic.4,5 In either case, accurate information allows the goals of medical intervention to shift and allows family and friends time to plan for gathering in a timely fashion to honor the dying child. Effective and compassionate communication may even allow the child to be discharged from the ICU, when desired, to die at home, or to die in a more private area of the hospital.1,55,61

Sometimes, in response to our own pain, medical caregivers communicate the news of a bad prognosis in a brief encounter and may use technical terms to “soften” the blow, or to avoid the conversation altogether or wait until the child is unconscious.35,62 Research on breaking bad news does not support prolongation of “slow codes” are ethically unjustifiable actions.67,68 Suggestions for breaking bad news in a way that is sensitive to the needs of the child and family, as well as the medical caregivers, are suggested in Table 51–3.

Recommendations for the next step should be presented, based on the team’s experience and on the goals and values of the patient, as well as the observations of patient and family members during the meeting and the hospitalization overall. Be sure that the benefits and burdens (including prolongation of suffering) of each potential care plan, the potential reversibility or irreversibility of the conditions being treated, the time frame for reevaluation, the projected future quality of life, and the comfort measures available if the ICU interventions are curtailed or discontinued are explained to the family in a manner they can and do understand (Table 51–3). Give reassurances that, if life-sustaining medical interventions are discontinued, the child will continue to receive attentive care for the relief of symptoms; describe the procedures to be undertaken, including the opportunities to observe important customs and rituals and the visitation allowances.36

It is the author’s impression that most communication about forgoing life support concentrates on what will be stopped and not what will be added. It is my practice to suggest that, while we cannot help your child live longer, we can help you properly celebrate the wonder of this child, his relationships, his value, and the impact he has had on the world. Suggestions for accomplishing this celebration of life are offered, such as inviting friends and extended family, bringing the child’s own clothing and dressing him or her after a bath (the parent may choose to do this or ask to have the nurse do this) as well as removing unneeded medical devices (“To make him your child again, and not a patient”), making a 3D plaster hand mold (“so you will always have your child’s hand to hold”), bring in photo albums to remember the good times that were had, bring a camera or video to commemorate the celebration, bringing members of the congregation to provide spiritual support and guidance, bring the child’s favorite music, toys, videos, or other means of demonstrating the child’s specialness. One family brought balloons and a sheet cake; another brought in the teen’s make-up and favorite cologne; a third played videos of the teen’s victorious football game. Have easy access to a rocking chair or couch for the parent to hold the child (no matter how large the child). Offer unlimited coffee and drinks. Offer to transfer the child to a more comfortable setting, where more supporters can comfortably be present. However, this agreement must usually be predicated by an agreement to terminate the ventilator within hours of transfer.

Avoidance of the topic of a poor prognosis and the performance of “slow codes” are ethically unjustifiable actions.57,68 They deprive the family and patient of the potential for peaceful and final goodbyes, a commonly lamented missed opportunity. We have so much to share and so much healing to offer if we would just be honest and compassionate with our families. Death is inevitable. Missed goodbyes are not.

### Aggressive Symptom Management

The symptoms most commonly suffered by dying children are poorly documented but include pain, seizures, problems with secretion control, dyspnea, vomiting;69 perceptions of isolation and abandonment;16 existential pain (“What did my existence mean to the world?”); relational pain (“I was mean to my brother and I need to say I’m sorry”); and spiritual pain (“What could I have done to deserve this?”). In the ICU setting, where life-supporting technologies are nearly always in use at the time the decision to forgo further life-sustaining measures is made, the most common symptom-distress risks are dyspnea, pain, and seizures (personal observation). Thus, meticulous care at the time of ventilator withdrawal, including the continuous presence of the physician and/or nurse, and protocols for symptom management are key to the effective prevention or immediate management of symptom distress.71

| Table 51–3  |
|----------------|----------------|
| Evaluating Treatment Options | |
| • How realistic is it that the intervention will cure the disease? | |
| • If not able to cure the disease, will the intervention prevent progression of the disease? | |
| • Will the intervention improve the way the child feels? | |
| • Could the intervention make the child feel worse? If so, for how long? | |
| • What will it be like for this child to go through this treatment? | |
| • What is likely to happen without the intervention? | |
| • Will the intervention change the outcome for the child? | |
| • What is the likely impact of this decision on the family? | |

It is helpful to most families to affirm their decision and to explain the expected events in advance of their occurrence.

You are a brave and loving family. You have recognized that we cannot keep Brandon alive and have opted not to prolong his death, but, rather, give him a proper goodbye, surrounded by love, friends, and family. I know this is the hardest thing you have ever done. Brandon is lucky you are willing to do this for him. Do you have any concerns or questions I can address? If not, let me go over the procedure for tomorrow. In order to keep Brandon comfortable, we will discontinue his IV fluids the evening before so that he is not gurgling. We will move him to the larger room in the morning. After your family and friends celebrate Brandon’s life, when you and your family are ready, we will suction Brandon’s breathing tube and then remove it from his windpipe. We will also stop the blood pressure medication. Brandon may breathe in a funny pattern—sometimes shallow and quick, sometimes like a yawn or hiccup, and sometimes not at all. We will stay with you; if he looks uncomfortable, we will give him medications every 5 minutes until he looks more comfortable according to you and to me. I will not leave your side until he is looking as comfortable as possible.

The SUPPORT (Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatment) trial demonstrated that current adult ICU practice does not address the issue of discontinuation of life support adequately: it is unlikely that pediatric and neonatal ICUs do any better. In fact, a recent paper demonstrates that even the most respected institutions frequently fail to effectively manage pain. When attended to by a skilled multidisciplinary team that focuses on these issues as primary concerns, these symptoms are usually successfully addressed. (For more in-depth explanations of the management of these symptoms, see Part II, Symptom Assessment and Management.) A few overarching principles deserve further mention, however.

**Pain**

Pain is a subjective phenomenon. It is not measured by vital signs, presence or absence of sleep, blood or imaging tests, or the size of an incision. Pain severity is most accurately assessed when measured by patient self-report. Several tools exist to facilitate a child’s pain self-report, including a visual analogue scale (a 0–10-cm line ranging from “no pain = 0 to the worst pain you can imagine = 10. Mark the amount of pain you are experiencing.”); the categorical scale (no pain, a little pain, medium pain, and very, very bad pain); and the numerical scale (“0–5, 5 is the worst pain you can imagine”). Children 4 to 7 years of age respond well to the faces scale (categorical, with face cartoons to illustrate), the best validated being the Bieri scale, which has too many choices. Options also include the Oucher scale, Eland color tool, and Wong–Baker faces scales, among others. Of course, when children are sedated or unable to communicate because of developmental immaturity, caregivers need to interpret the child’s pain. There are a number of scales validated for the pediatric ICU patient, including the Premature Infant Pain Profile (PIPP), children’s pain checklist, FLACC (Face, Legs, Activities, Cry, and Consolability) and Comfort scales. Primary nursing assignments facilitate this assessment. Parents also are important resources for pain assessment.

The severity of reported pain dictates the category of pain relievers needed to relieve the pain, irrespective of etiology. For example, according to the World Health Organization (WHO) pain management guidelines for children, severe pain, regardless of etiology, demands prompt treatment with a “strong opioid,” such as morphine, hydromorphone (Dilaudid), fentanyl, or methadone. In the vast majority of cases, pain can be controlled.

Dying adult patients often have pain. The occurrence of pain is not well documented in the terminally ill pediatric patient, but suspicion of pain must remain high, and presumptive treatment should occur if there are indications it is present. Where possible, each pain needs to be categorized not only by severity, but also by character (burning, gnawing, throbbing, sharp, crampy), location and radiation, duration, continuous or intermittent nature, and precipitating and relieving factors. The quality and timing of the pain suggest the etiology of the pain and dictate the most efficacious treatment. This ideal is very difficult to achieve in young or developmentally disabled children and in sedated or intubated patients. An empirical judgment of the etiology and physiology of the pain often dictates the choice of intervention in the ICU setting.

Constipation, a common problem in the ICU setting, may present with intermittent, poorly localized, crampy abdominal pain. Treatment with opioids would not be as beneficial as a heating pad and a laxative or, when needed, an enema. Burning pain in a patient who received neurotoxic chemotherapy is a sign of neuropathic pain, that is, pain related to nerve injury. This pain is best treated with “adjuvant pain relievers” (medications most often used for other purposes, but which are effective in the relief of certain types of pain), such as tricyclic antidepressants and anticonvulsants along with “traditional” pain-relieving agents, in addition to stopping the offending agent if it is still in use. Unfortunately, in the ICU setting, some adjuvants may not be of benefit because they must be given for at least 1 week to achieve effectiveness, or they are only available as tablets and capsules. Thus, depending on the patient’s circumstance, the best pain management may be the use of nonpharmacological techniques, surgical, and anesthetic techniques where indicated, and aggressive use of traditional pain relievers, including opioids and topical agents, such as topical lidocaine patches.

Concerns about addiction, a psychological phenomenon of craving a drug despite harm to oneself (which has been shown to be rare in the medical use of opioids), are inappropriate in the ICU. Around-the-clock analgesics should be provided, particularly in the setting of surgery, multiple trauma, and recurrent procedures. Medications should be titrated to pain control using acetaminophen or nonsteroidal antiinflammatory medications as background pain relief unless contraindicated,
in addition to opioids for more severe pain, opioids and local anesthetics for procedure-related pain, and “adjuvant” analgesics for neuropathic pain. “As needed” or PRN medications should be ordered for the alleviation of increased pain as well as the expected side effects of opioids, such as nausea, pruritus, urinary retention, and somnolence (when it is undesirable). Constipation is a predictable side effect of opioid analgesia that does not resolve, but it is less of an issue in a child who is expected to die within 24 hours, as do most ICU patients undergoing the withdrawal or withholding of life-sustaining medical intervention. Changing the specific opioid used may also be considered for the management of refractory opioid-induced side effects when the child’s expected survival is longer. Alternative routes of pain relief, such as epidurals for children who are excessively somnolent or who become delirious with systemically administered opioids, may be of benefit in some cases.

Respiratory depression in the face of pain is an uncommon occurrence, despite aggressive use of opioids for pain relief. Irregular breathing caused by pain can often be smoothed and regulated to promote optimal gas exchange when pain is relieved. Pupillary size can help in the assessment of the opioid titration of preverbal or nonverbal patients (personal observation).

Pain can be treated effectively only if the results of the intervention are reassessed at the appropriate interval, based on the pharmacokinetics of the medication and route used. If pain relief is not achieved, an additional intervention should be undertaken immediately, not at the next timed dosage. For instance, if the patient reports severe pain (a score of 10/10) and morphine is administered intravenously (IV), the child should be reassessed in 15 minutes. If the report remains the same (“severe pain, pain scale score 8/10”), an additional dose of morphine should be administered immediately. This process should continue until the child is comfortable. There is no maximum dose of pure opioids. The proper dose is the dose that controls the pain. The goal is not to sedate the child unless the child desires this; the goal is to relieve the pain. On occasion, pain can be relieved only with aggressive analgesia and sedation.

Medication for consistent pain should be administered on a schedule, around the clock, or by constant infusion (not PRN). Additionally, medication for breakthrough pain (pain occurring despite the regular administration of medication) should be prescribed. The reader is referred to the Agency for Health Care Policy and Research (AHCPR) guidelines for pain management, available from the U.S. federal government online, as well as other standard pain references, and to Chapters 6 and 55 for further details regarding pain management. Successful pain management cannot occur unless pain is regarded as a priority, pain is regularly assessed and reassessed, and pain scale scores are documented routinely.

**Dyspnea**

Often children or their families prefer to forgo mechanical ventilation if there is no reasonable expectation of improvement or cure, with the exception of some patients with neuromuscular disorders who are still young and intellectually intact. When the choice is to discontinue or to not initiate mechanical ventilation, scrupulous attention to the management of dyspnea must be explained and promised to the child (if capable of participating) and the family, and the promise must be realized. The idea that there may be a trade-off between relief of dyspnea and sedation, or even a slightly earlier death, must also be broached and preferences elicited. Most families express preferences for enhanced comfort even in the face of a potentially foreshortened survival. However, this is not a foregone conclusion and, as has been previously reported, patients occasionally are much less distressed than anticipated and are able to enjoy a few hours or even days with carefully titrated opioids, as needed.

In the few studies reviewing duration of survival related to the administration of morphine during withdrawal of mechanical ventilation, however, patients of all ages actually survive longer when liberal doses of morphine are used to ease the dyspnea. The goals of care must be clear in everyone's mind before proceeding, lest the tragedy of perceptions of wrongdoing plague survivors.

Dyspnea is a symptom that is even more distressing than pain to experience or witness. It is difficult to control and requires intensive hands-on management and reassessment. Several nonpharmacological approaches can be helpful, such as sitting the child upright, having a parent or other close family member or friend present, saying soothing words, and touching the child. In addition, having a small fan blow air across the child’s face has been helpful in the hospice setting.

There are no published data on the treatment of dyspnea in children; the few small controlled studies done support the use of opioids as the pharmacological agents of choice in the management of dyspnea. Clinical experience has shown efficacy of opioids in alleviating dyspnea as well. The dose of opioids that is optimal is the dose that effectively relieves the dyspnea. This dose must be established by titration to clinical effect. Again, there is no maximal dose.

Various recommendations for the pharmacological management of dyspnea exist. Regardless of the protocol used, it is imperative that the child be continuously observed and repeatedly treated until symptom relief is achieved. The dose should be rapidly and aggressively escalated if ineffective. The author’s preference is to use IV preparations in the setting of extubation to gain rapid control. For example, if the child is receiving 5 mg of morphine IV per hour, the bolus dose would be 5 mg if dyspnea occurred at extubation. If the initial dose is totally ineffective, the next dose should be 50% to 100% higher, 7.5 to 10 mg. If, 5 minutes later, the patient is still in extremis, the next dose would be 50% to 100% higher. Often, children respond to these first few doses, and the dyspnea is controlled without loss of consciousness. The expected response to opioids is gradual slowing of respirations to a more normal level; respirations do not suddenly cease unexpectedly. Reversal with naloxone or other opioid antagonists should rarely, if ever, be undertaken. The recommended procedure, when done, is to dilute the naloxone 1:10 and administer it very slowly, repeating every few minutes as needed.
Benzodiazepines alleviate the breathlessness associated with anxiety but not the sensation of dyspnea itself. Administration of diuretics to children with pulmonary edema, withholding IV fluids or enteral feedings, or adding anticholinergic agents may decrease excess secretions. Thorough suctioning of endotracheal tubes before extubation of mechanically ventilated children is helpful as well. For more information on dyspnea, the reader is referred to Chapter 13.

**Palliative Sedation**

Occasionally, a technique known as terminal sedation is necessary to control symptoms, most often pain, dyspnea, and intractable seizures. Within the palliative care community, palliative sedation has become a generally accepted plan of care for adults in the case of otherwise uncontrollable symptoms, though somewhat more reluctantly so for children who cannot always independently consent in advance.92 Although considered an “acceptable and justifiable form of euthanasia or physician-assisted suicide” (PAS) by some,104–106 others see palliative sedation as the extension of the tenet that, above all, the health care provider’s duty is to relieve suffering. The intention is not to bring about the demise of the child (as in the case of PAS and euthanasia),107,108 but rather to control the symptom, even at risk of death (principle of double effect).

Regardless of the philosophical underpinnings that lead to the practice, palliative sedation is widely regarded as the only humane solution to an otherwise uncontrollable and severely distressing problem. It is only undertaken after all other attempts at symptom control have failed and with the full agreement of the child and family.92 Full explanations of the inability to reverse the underlying process must precede this decision. Some practitioners also use barbiturates, particularly helpful in relieving labored or agonal respirations, for the management of terminal dyspnea and pain.103

Unfortunately, significant discomfort and uncertainty on the part of many critical care practitioners impede the availability of these therapeutic strategies. Clinicians fear being perceived as the proximate cause of death due to the administration of opioids,97 despite numerous well-known ethical opinions that the relief of symptoms is the primary obligation to the dying patient. Critical care nurses giving opioids to terminally ill patients withdrawn from mechanical ventilation reported that they believed they were engaging in euthanasia.109 On the other hand, the administration of neuromuscular blocking agents, impeding the ability to assess dyspnea, can constitute euthanasia and should be avoided whenever possible.110

**Extubation Technique**

Prior to extubation, engaging in family-centered rituals is important (see Case Studies below). This allows unhurried family time while the child is still pink and breathing. As the family is approaching readiness to extubate, they should be informed about what they can expect after extubation, making this difficult time easier. (“He may turn blue; we will treat this with morphine and oxygen if he looks uncomfortable. He may not breathe at all or may breathe comfortably for some time. I do not know how long he will live, but I expect it will be on the order of (minutes, hours, days). I will stay with you until he is comfortable.”) Positive thoughts about extubation are important to share as well. (“This will be the first time you see your daughter’s beautiful face without tape and a tube interfering”; “I am giving you back your son as a child, not as a patient”; “You may be able to hear his voice for the first time in a while,” depending on the age and circumstances of the child.)

The author’s practice, both as an intensivist and as a palliative care physician tending primarily to pediatric ICU patients, is to avoid “terminal weaning,” or the gradual decrease of mechanical ventilation support. Terminal weaning allows the child to be dyspneic as well as to have the discomfort of the tube on the nasal mucosa and pharynx until he or she becomes unconscious, either from sedatives or carbon dioxide narcosis. Continued intubation also masks the severity of the child’s distress and may lead to inadvertent undermedication. Thus, my practice is to extubate without weaning and provide “blow-by” oxygen as desired. It is critical to constantly assess discomfort and take steps to alleviate it, whether this consists of the simple act of having a loved one stroke the child’s hand, giving reassurances of love, or rapidly increasing dosages of opioids or other interventions. The policy of decreasing supplemental oxygen in hypoxic children puts them at increased risk of discomfort. On the other hand, nonhypoxic children do not require the inconvenience and discomfort of supplemental oxygen. Another reason to prefer rapid extubation is that the tape and endotracheal tube create physical barriers between the child and family, who otherwise may feel more freedom to ply the child with kisses, indicating continued love and devotion, attending the devastating symptom of perceived abandonment.

Children with significant central nervous system compromise may have noisy respirations due to floppy pharyngeal soft tissues. The family needs to be made aware of this possibility before extubation. Management strategies include repositioning, discontinuation of IV fluid or enteral intake well in advance of extubation, administration of diuretics and/or anticholinergic medications, aggressive suctioning of artificial airways before removal, or placement of a nasal trumpet. The latter, however, creates a physical wedge between the child and family and should be avoided when possible.
for survival rather than quality-of-life considerations. Reassessing the goals of treatment only when the child is dying deprives the patient of choices that the child and family may make earlier to enhance the quality of life rather than extend the duration of life. Children who cannot be cured and their families often have preferences regarding medical interventions. Their opinions are not knowable by the medical team a priori; they must be actively solicited. In addition, the child’s perceptions of discomfort relative to various medical interventions may be very different than the medical caregivers’ perceptions. In fact, regardless of the presence of a terminal prognosis, patients and their surrogates have the right to forgo LSMI.

Thus, the current practice of withholding discussions regarding burdens and benefits of ongoing LSMI is unsupportable. Refusing to honor a child’s or surrogates’ requests to stop LSMI until the child is certain to die is even worse. Patient suffering must play a much more prominent role in the decision-making process if “good deaths” are to be attained for a higher proportion of patients. On the other hand, physicians’ personal biases regarding quality of life and economic motivations for the withdrawal of LSMI should not play any role in the decision to forgo treatment.

Finally, it has been shown that physicians’ practices in withdrawing medical interventions are more determined by personal idiosyncrasy and fears of litigation or accusation of wrongdoing than by the patient’s comfort. In several studies, vasopressors were withheld first, oxygen next, and mechanical ventilation next. However, oxygen supplementation and extubation may be preferred and more comfortable. In addition, withholding antibiotics and allowing the peaceful death associated with sepsis, without a trip to the ICU, may be the most humane option available for some children. In other cases, forgoing nutrition may ease nausea, and forgoing hydration may decrease the discomfort of renal failure or congestive heart failure. Obviously, much depends on the child’s symptoms, the clinical situation, and the child’s and family’s values and preferences. Effecting a philosophical change among medical decision-makers to proactively solicit children’s and families’ perspectives may be accomplished by educational intervention, although it is likely that cultural changes within institutions and protocol-driven practice may have more promise.

**Review of the Patient Care Plan**

After it has been determined that the child and family no longer subscribe to the goal of prolongation of life, because either the burdens are too great or the effort is “futile,” the care plan must be reviewed in detail. The likely mechanisms of death must be determined and plans should be made to ameliorate associated symptoms of these mechanisms. It is not uncommon for the child to have several potential mechanisms for death; often, one route can be anticipated to be the most comfortable, such as dying from hyperkalemia or sepsis as opposed to hypoxemia. In this case, Kayexalate or dialysis as well as antibiotics should be discontinued, whereas oxygen by nasal cannula or “blow-by” if possible should be continued.

Anticipation of likely symptoms and care plans that address them proactively are essential. For instance, if the child is likely to have seizures but cannot swallow, rectal or parenteral rapid-onset anticonvulsants should be written as a PRN order. Developmentally appropriate explanations about the possible course of events should be given to the child and family unless they refuse this information. It is unwise to predict an exact time of death, but approximations (with significant margin for error, e.g., minutes to hours, hours to days, days to weeks) are helpful for the family to arrange for the child’s other loved ones and friends to visit before or be present at death.

All interventions that either interfere with comfort or that do not enhance it should be discontinued. For instance, laboratory tests are not designed to enhance comfort. Sometimes in clinical practice, laboratory parameters, such as platelet counts, are monitored to prevent symptoms such as bleeding from arising. However, it is just as efficacious and less intrusive to monitor the patient for clinical bleeding and treat if and when it arises, if desired. Medications that do not enhance comfort, often including antibiotics, should be considered for discontinuation. Even feeding and IV fluids may interfere with comfort if the child has pulmonary edema, heart failure, or renal failure; a decrease in or cessation of these therapies may enhance the child’s comfort.

Monitors, such as pulse oximeters, cardiorespiratory monitors, and the like should be removed. They create physical barriers to the closeness of loved ones with the child, distract them from attending to the child with their color displays and flashing lights, create distressing alarms that all have agreed not to respond to, and create a reason for the health care team not to enter the room. (However, some families become so attached that removing these devices seems to them to be a form of abandonment and should not be carried out). Visitation restrictions and many of the usual rules should be reconsidered. Maximization of the child’s or even invitations to family members to climb in bed with the child should be facilitated. Letting the family bathe the child and dress him or her in clothing of the child’s or family’s choice is often helpful. Other special requests should be honored if at all possible.

**Transfer to Alternative Care Settings**

When children are acknowledged to be dying, it is common for large numbers of loved ones to gather. They need to support the child, parents, siblings, and each other. Sometimes they may desire to perform rituals that may be difficult to accommodate in the ICU setting. Thus, consideration for transfer to an alternate care setting should be made. If the child is anticipated to live for a few days once ICU interventions are discontinued, referral to hospice in the home care setting may be an option. Usually a 1- to 2-day stay in the hospital to ensure “stability” and to provide family caregiver teaching is needed.
Alternatively, if the child will have significant distress in his or her final days, or the child and/or family prefer to stay in the hospital, admission to the floor, or preferably a palliative care unit, may be the best plan. As large a room as is needed to accommodate the child and his or her loved ones should be provided, if possible.

**The Butterfly Room**

At the University of Texas Medical Branch at Galveston, we have created an alternative care unit for children with life-threatening conditions called the Butterfly Room. It is a homelike setting distinctly different from any other room in the hospital, with carpeting, wallpaper with butterflies, a kitchenette, TV, Nintendo and VCR, pull-out sofa beds and chairs, padded window seats overlooking the Gulf of Mexico, and storage, as well as a place for the child to sleep. It is as large as two semiprivate rooms and is designed to accommodate the entire family.

One use of the room is for ICU patients who are expected to die within minutes to days following extubation, and who are thus generally not candidates for transfer home. After consultation with the family, it is our practice to review the medical orders and discontinue all laboratory tests, all invasive equipment (extra IV sites, nasogastric tubes, urinary catheters, etc.), all monitors (including the recording of vital signs, fluid balance, and weights), and all medications other than those contributing to the comfort of the patient. Orders not to resuscitate (DNR) are written with the family’s agreement. The child, who is still being mechanically ventilated, with vasopressors infusing as needed, is then moved from the ICU to the Butterfly Room. Resuscitative medications, such as atropine and epinephrine, are brought in the elevator for unstable patients to ensure that the family will have a chance for final togetherness, but these medications have never been used. Cardiopulmonary resuscitation beyond these medications would not be done, however.

In the Butterfly Room, the child’s loved ones are invited to sit in a rocking chair, or, in the case of an older child, they are invited to sit on a couch and hold the child. Even young siblings participate in this activity. Usually, each family member in turn will whisper loving thoughts and memories to the dying child. Numerous photographs are taken in most cases. The family is offered the opportunity to bathe the child, make handprints, footprints, or handmolds and dress the child in clothing of their choice. Other rituals specific to the family or their heritage may be undertaken. Once these events have taken place, with the family’s acknowledgment of readiness, the child is extubated. Opioids, benzodiazepines, and blow-by oxygen are immediately available. The multidisciplinary hospice team, including a spiritual leader of the family’s choosing, if desired, a social worker, a child life therapist for siblings, and the nurse and physician remain either in the room or close by, often mingling among the distressed relatives and listening to their concerns, as well as attending to the patient’s symptoms.

**Consideration of Suffering and Future Quality of Life**

It has been documented that, against the legal and ethical principles currently in place, physicians often refuse requests to forgo life-sustaining treatment. Since discontinuation of LSMI often leads to the patient’s death, this action must be undertaken with caution, ensuring that the child is not making decisions on the basis of depression or the family making decisions based on exhaustion or financial pressures. However, refusal of LSMI may well represent the child’s and family’s assessment of future quality of life, often based on the experience of lived, progressive disability and chronic illness, or on long-held values. Surrogates’ (or parents’) duties are to act on the child’s wishes and in his or her best interests. This role is often not clear and requires explanation. Surrogates, in the author’s experience, more often request prolongation of a child’s death due to guilt and fear, rather than discontinuation of LSMI too prematurely. Thus, overriding requests to terminate LSMI must also be done with significant forethought and analysis. In addition, the motivation for requests to continue LSMI in the face of an extremely small likelihood of survival, or very large chance of a significantly poor quality of life, must be explored fully. Issues of guilt (“What do you think caused his problems? You were away at work when the accident happened?”) and loss (“Tell me about what has happened to your family as a result of your child’s condition?” “It sounds like you’ve been through a lot. I wish I could make your child healthy and make it all OK again but unfortunately, there are limits to what medicine can do. The best we can reasonably hope for, medically, is . . . Does that change your perspective on treatment options? Our recommendation, based on all you’ve told us and our assessment of your child’s condition is . . .”). Eliciting and demonstrating respect for the family’s and child’s (where applicable) values can be helpful in resolving these dilemmas.

**Notification of Death**

Unless there are extremely extenuating circumstances, even if the death is expected, most experts strongly encourage that the notification of death be done in person. (“Mrs. Smith, I am afraid I have some bad news. Could you come in to discuss it?”) Empathy can be more easily expressed in person by sitting close to the parents and siblings at the time of the discussion, perhaps even giving the bereaved a hug, or shedding a genuine tear. These small tokens of warmth and understanding help the family to know that the medical team cared about the child as a person. Additionally, insistence that the family come in allows them to see the dead child, which facilitates the acceptance of the fact that death has occurred and allows the family to participate in important rituals, such as bathing the dead, sometimes assisting in the removal of equipment, or sitting vigil as some cultures require. These efforts result in
improved bereavement outcomes, particularly for siblings, who often imagine the child has not actually died.

Bereavement Follow-Up

Studies have repeatedly shown an increased mortality rate of surviving spouses in the year following death. A recent study of bereaved parents in Denmark showed a marked increase in mortality from natural (maternal) and unnatural causes (maternal and paternal), though no similar study of siblings has been undertaken. The divorce rate among parents the first year after a child’s death is higher than the national average. (Over the long term, however, the proportion returns to the national average of 50%.) It is not yet known what interventions are most effective for bereaved parents. However, a recent study indicates that a caring attitude of the ICU staff has short-term and long-term impact on parental adaptation to their loss. Moreover, even for parents whose child died a violent death, attendance at a support group and maintenance of religious connection can enable better adaptation in the long term. In addition, some lessons may be derived from studies of bereaved spouses.

A simple strategy of routinely sending a bereavement card 2 weeks following the death of a hospitalized patient was investigated. One year later, the bereaved survivors could consistently and without warning retrieve the card, indicating the importance to them of such a gesture. Remarks of survivors of patients who had died in the ER included, “At least I know my husband died among caring people.” Attending the deceased’s funeral is an even more powerful demonstration of caring and may provide relief for the medical caregiver as well.

If an autopsy was performed, families need a face-to-face appointment (autopsy conference) with the treating physician to explain the autopsy findings in understandable terms. Often, this explanation gives the bereaved family a profound sense of peace by affirming the cause of death, affirming the irreversibility of the problems, or determining a cause of death that was unknown antemortem. It is particularly important to rule out heritable conditions that may affect surviving or future siblings. This process has even been found to improve adaptation to loss. The autopsy visit also allows monitoring of the family’s grieving process and provides the opportunity for referral to counseling, if needed, for pathological grief reactions. In the absence of a face-to-face session, families consenting to an autopsy often complain that they had no follow-up and express anger and suspicion about the motivations for the autopsy. This postdeath conference is also helpful for families who did not consent to autopsy, to answer questions and monitor for adaptive grieving. Referrals can be made for families needing counseling or other assistance.

A memorial service may also be offered. This may take several forms; two are particularly suggested for the ICU. Some children’s families who have either come to the ICU recently, or others who have particularly bonded with the staff due to a child’s prolonged stay or for other reasons, may be invited back to the unit with the families of a few other children who have died within the last month or 6 weeks for a ceremony of sharing. The family may bring a picture of the child, and the family and staff can exchange memories of the child. Songs may be sung, poems may be read, and prayers may be shared. Gratitude and admiration may be exchanged. In addition, all families bereaved of children could be invited to a group memorial service conducted on an annual or more frequent basis. One study of the bereavement care of families grieving a child’s traumatic death included family contact at the hospital after discharge from the ED, attendance at the funeral home, a home visit, a meeting at a restaurant with the parents and 15 parental supporters 2 months following the death, and a parental interview approximately a year after the death. The latter were for the purpose of educating parental supporters about the course of grief and the need for long-term support. Even a simple phone call would be appreciated but is rarely received.

Grief of Medical Caregivers

Not only do children suffer and families and loved ones grieve, but we as medical caregivers grieve for our patients, their families, and ourselves. We are exposed to pain and grief both vicariously and in empathy and are forced to confront the certainty of our own and our fellow humans’ mortality on a daily basis. In caring for dying children, we are threatened by the reality that our own children, too, could die. The ability to share these feelings in a supportive environment, without sanction, and the ability to take leave to attend funerals can assist in increased job satisfaction and retention of highly skilled critical care personnel. It can also help to reinforce the humanity that makes us the medical caregivers we can be.

Palliative Care for All Patients

The focus on prevention of suffering and on the person as a whole should not be reserved solely for the dying child. All children, from clinic patients to ICU patients to dying children, should have access to the best that medicine has to offer. As a wise man stated very long ago, “The medical care provider’s duty is to cure sometimes, to relieve often, and to comfort always.”

Teaching End-of-Life Care

Once palliative care philosophy and methods are embraced, they should extend beyond the ICU. Ongoing efforts to teach the principles and practice of palliative medicine must occur to ensure that our trainees are as capable as possible of carrying on the tradition of humane and person-centered end-of-life care. Several courses are described in the literature and could easily be adapted for use in other settings.
of training, our trainees will inadvertently contribute to the already unimaginable pain of a child’s death.

The medical student population is probably the one that on a daily basis, offend the parents the most . . . I have been vocal with residents, like this person needs 101 in how to work with a parent . . . . But there is no real formal process set up for that feedback.
—Tina Heyl-Martineau, parent, 2001 (in Field & Behrman [2002], reference 1, p. 328)

Recommendations For Implementation

Improved end-of-life care begins with more highly focused attention on the individual child and his or her preferences and values. Pediatric and neonatal ICU practitioners are the caregivers for the vast majority of children who die; thus, they must have expertise in palliative care. Some recommendations to enhance end-of-life care in the pediatric and neonatal ICU setting are:

• Admission procedures should include a values history; solicitation of any advance directives for older, chronically ill children; and discussion of expressed preferences in light of the child’s current situation. This should not be reserved only for imminently dying children. Waiting until that time only increases the chances that the child’s preferences will never be known and the family’s guilt will be unnecessarily increased in the event they are later called upon to consent to the withdrawal of life-sustaining medical interventions. Good coordination with primary care providers and specialists who have cared for the chronically ill child can be enormously helpful.

• Attention to pain and the relief of other symptoms, both during procedures and more generally, must become a priority for all children. This can be accomplished only with training and appropriate documentation procedures, as well as emphasis by supervisors and attending physicians.

• Improved communication techniques must be employed that allow children or their surrogates to understand their options in a supportive and unbiased way. Guilt, missed opportunities, love, and existential and spiritual issues should be included in these discussions. Again, training must be developed and carried out. The importance of these issues must be emphasized, demonstrated, and reflected in the practices of the opinion leaders within the unit.

• Cooperation, respect, and regular interdisciplinary rounds among the disciplines of nursing, medicine, social work, pastoral care, and, possibly, palliative care (and others as indicated, such as pharmacy, occupational therapy, physical therapy, child life) will enhance the larger understanding of the child and his or her needs and facilitate the team’s ability to assist the child with the accomplishment of his or her goals.

• Establishment of a bereavement follow-up program, including the mailing of bereavement cards, autopsy debriefing or postdeath sessions, “sharing sessions,” and memorial services will improve the bereavement outcome for surviving loved ones and ICU staff.

• Excused paid absences for funeral attendance and staff support sessions will prevent burnout and turnover and allow the retention of the ideals and values that brought each staff member to the healing professions.

Summary

Infants die primarily of congenital defects, prematurity, and SIDS. Children older than 1 year of age die primarily from trauma, thus predisposing them to die in ICU settings. The principles of palliative care must be applied to all children, even those whose fate is to die in the ICU. Our challenge, as practitioners of emergency and pediatric critical care medicine, is to provide each of these children a “good death.” This can be achieved by intensive attention to the child’s and family’s perspectives and goals, communication within the team and with the child and his or her loved ones, dedication to the meticulous management of symptoms, particularly during procedures—the most common source of discomfort in ill children—and effective bereavement follow-up.

Case Study

FL, a Near-Drowning Victim

FL, a 14-year-old Pakistani boy, suffered a near-drowning episode that compromised his central respiratory drive mechanism and left him neurologically devastated. His family was informed that life-sustaining medical interventions were futile. They agreed to move him to the Butterfly Room to achieve a family-centered death. Orders not to resuscitate were written in a clear and detailed manner. All laboratory analyses were discontinued and all monitors were removed. Medications were reviewed and all were discontinued. Morphine and lorazepam were added for the management of dyspnea, IV fluids were discontinued, and scopolamine was administered for terminal secretions. One IV catheter was left intact, but all other invasive monitors, such as nasogastric tubes, urinary and arterial catheters, etc., were removed. During his transfer from the ICU to the Butterfly Room, FL remained mechanically ventilated.
Although FL had a small family, he belonged to a close-knit community. Thirty people of all ages came to be with him on his final day of life. They encircled the boy’s bed, chanting but not touching him. After approximately 30 minutes, they approached the team and announced their readiness for the discontinuation of mechanical ventilation. One caregiver stated that she was unfamiliar with Pakistani traditions and customs, but had not observed anyone touching FL. She suggested that if touching was allowable and desirable for them, they were welcome to do so. The whole spirit of the group changed, with the circle drawing nearer the bed and men openly grieving and weeping, holding the boy and their wives, as well as each other. People stroked FL’s face and body. After an hour, they again informed the team that they were now ready to have the mechanical ventilation discontinued.

FL was suctioned and extubated and needed little pharmacological intervention. His loved ones chanted from the moment the endotracheal tube was removed. Each visitor, in turn, put small amounts of holy water in his mouth. Although the water bubbled out of his nose, a caregiver wiped it away, giving “permission” for the next person to engage in the ritual. After 27 minutes of nonstop chanting, FL died. A peaceful hush fell over the room, and all eyes turned to the same window leading to the outside.

CASE STUDY
LF, a Newborn with Hypoplastic Left Heart Syndrome

LF, a newborn, was diagnosed with hypoplastic left heart syndrome. After a full explanation of the surgical options, the family opted for palliative care. The mother preferred never to see the baby again, because she feared bonding with her child. The baby was in the ICU but, because of her parents’ decision, was not receiving ICU interventions. The parents were approached about the Butterfly Program, providing surrogate parents, and moving the baby to the Butterfly Room; they agreed. They decided to visit the baby the next day. She was wearing normal baby clothes, being cared for and appearing like any other baby. When they saw that the baby did not need highly skilled care, they felt that they could care for her themselves at home with the help of the Butterfly Program. The next day, the parents took their daughter home. LF lived well there and visited many churches for blessings, went to numerous restaurants, had house guests, received several hospice visits, and was asymptomatic until her final day at 2 weeks of age, when she began to vomit and become intermittently cyanotic. The Butterfly Team (nurse, social worker, and physician) was summoned to the home. Additional explanations of what was happening and assurances of the child’s comfort were provided. The baby received one dose of morphine, but the family assessed that she did not need more. She died in her mother’s arms 8 hours after the first cyanotic episode.

CASE STUDY
GG, a 7-Day-Old Infant with Anuria

GG, a 7-day-old male infant, was anuric and referred from a hospital located 3½ hours away by ground transport from the tertiary care hospital. Diagnostic studies showed complete absence of a urinary collecting system and hypoplastic lungs. He underwent intubation for acidosis and respiratory insufficiency; meanwhile, the implications of the findings were communicated to his parents.

GG’s 7-year-old brother had begged his parents for a new baby, resulting in GG’s birth. He had seen “his baby” for a total of 20 minutes; now the baby was far away and dying. It was unlikely that GG could live long enough to be transported home without life support. The extended family and friends were unable to arrange transportation to the hospital in a timely manner. In addition, they preferred GG to die at home, if at all possible.

The ICU social worker arranged for Medicaid to cover the ambulance expenses of transporting the intubated patient to his home. The Butterfly Team arranged for the ambulance to be met at the house by a local hospice team, which had orders to extubate on arrival, and had medications for dyspnea. The baby was taken to the living room, where his brother and family awaited him. His brother was the first person to hold him. A peaceful 3 hours were spent, and the baby died at home with minimal symptoms.

CASE STUDY
EC, a 7-Month-Old Infant with Severe Neurological Compromise

EC, a 7-month-old infant, had a rare chromosomal anomaly resulting in severe neurological compromise. He had unremitting gastroesophageal reflux, causing recurrent pneumonia and ICU admissions, and, according to his parents, constant sensations of choking. His family agreed to a fundoplication to enhance his daily comfort rather than to extend his life. The family realized that he would not live very long because, during his entire lifetime, he had spent a total of 7 weeks out of the hospital.

Five days postoperatively, the fundoplication dehisced, and EC developed peritonitis. The family interpreted this as a sign to stop interfering with their son’s dying process. They accepted antibiotics but refused further surgery. After 2 days, they chose to take him home. Within 2 hours, he was on a commercial jet to his home, an 8-hour drive away. A hospice team met the family on the tarmac and drove behind them with medications. He arrived safely home and spent 3 days with his family, with frequent visits from the hospice team to ensure his and his family’s comfort. He is buried on the family property with a ring of evergreens surrounding his grave. His older sister wrote a poem about...
him. The family adopted a needy Mexican infant 2 years later. They are doing well.

CASE STUDY
DC, a 5-Week-Old Infant with Intraventricular Hemorrhages

DC was born after a 25-week gestation to a 41-year-old mother who had cervical incompetence. The mother underwent a tubal ligation at the time of DC’s birth. Her first child was born at 30 weeks’ gestation and had done well. Both parents were schoolteachers of young, disabled children.

DC suffered bilateral grade IV intraventricular hemorrhages early in his course. His parents did not understand the implications of this initially, and he continued an unstable course, with the development of severe bronchopulmonary dysplasia and frequent desaturation episodes. He also developed hydrocephalus. The prognosis became clear to the parents when DC was 5 weeks old, and they requested discontinuation of his life support. He was transported to the Butterfly Room and intubated. The family requested a rabbi and support from the Butterfly Team.

No one in his family had ever held DC because the referring neonatal team had felt that he was “too unstable.” When his mother held him to her chest and stroked her son for the first time, he became pink and his heart rate decreased from 180 to 140 beats per minute. The infant’s 20-month-old brother sat with him and had photographs taken. DC remained stable.

After some time, a conversation with the parents and aunts confirmed that they were making the decision to stop life support out of love for their child and concern for his suffering, that they had been good parents to him, and that their other son would always be a brother. The rabbi affirmed that their religion supported their decision. A description of what might happen postextubation was offered. The family understood and requested that the ventilator be discontinued. The mother held her son without the impediment of medical equipment, crying quietly to herself and rocking him with her husband, son, and sisters at her side until DC’s death 26 minutes later.

Over the ensuing months, the family frequently called the Butterfly Program social worker for counseling, and occasionally they met for lunch. They have been lost to long-term follow-up.

CASE STUDY
KD, a Child with Multisystem Organ Dysfunction

KD, a 2½-year-old boy, had one of 20 world-reported cases of a syndrome that caused multisystem organ dysfunction, primarily liver and digestive, as well as bone marrow. For most of his life, KD was hospitalized an average of 2 to 3 days per month for diarrheal or infectious episodes. He was extremely small for his age (one medical student estimated he was 6 months old on his last admission) but was alert, interactive, and able to talk, although assessed to be “delayed.” He enjoyed music and playing “air guitar.” His family loved him dearly and had made many sacrifices to ensure his well-being. His mother, the main wage earner, quit her job, and her husband became the sole source of family income. The family had to move to a new neighborhood.

During his last 2 months, KD was continuously hospitalized for severe diarrhea. After 1 month, KD began to require ICU interventions for sepsis episodes. After four episodes in the ICU over the course of 3 weeks, his parents approached the ICU team because they felt that KD, who was intubated for fungal sepsis and general debility, was not going to get better; they requested comfort measures only. They felt that their boy was not benefiting from life-sustaining medical interventions. This was difficult for his medical care team to accept.

KD and his family were moved to the Butterfly Room, where they were joined by an extended family and a circle of friends, a total of 45 people. All monitors were discontinued, and all laboratory testing was discontinued. The desired limitations of medical interventions were documented in the chart.

A discussion with the extended family affirmed that the decisions made for KD were loving decisions. Their chaplain visited and affirmed their choices and the support of the church. Then, a discussion of what KD might look like after extubation, the uncertain time course to death, methods of controlling symptoms, and the principle of double effect were explained. Handprints and footprints of KD were made, his mother and father bathed him, and he was dressed in an outfit that the family had brought from home.

KD was held by everyone in a rocking chair; some people, such as his 7-year-old sister, needed to hold KD several times before they were ready. The family took as much time as they needed while the Butterfly Team (nurse, social worker, child life specialist, and physician) circulated among the group, listening with empathy and encouraging communication. The family was reluctantly ready to stop the ventilator after 4 hours of rocking. As usual, the care team stayed with the family.

KD immediately turned cyanotic and was gasping postextubation; 100% blow-by oxygen was administered, as well as 0.1 mg/kg. IV of morphine. After 5 uncomfortable minutes and no effect on his breathing effort, 0.2 mg/kg of morphine was given. Again, 5 minutes passed with no change; the morphine was again doubled. This process continued until KD relaxed and no longer seemed to be dyspneic. He remained cyanotic, which, despite forewarning, was upsetting to his family. He died 2½ hours postextubation.

Bereavement follow-up included attendance at KD’s visitation and funeral by members of the care team; donations by a local service group of a truckload of clothing, paper goods, and shelf food, as well as Christmas presents; phone
calls and mailings; and invitations to a yearly memorial service, as well as to support groups. Three years later, the family is doing well.

End-of-Life Decision-Making in Pediatric Oncology

I watched the monitors for his blood pressure and his pulse. It was taking more medicines to keep those stable. Every day I would look at those numbers and I recognized it was getting harder and harder. His heart was not really pumping on its own. It was really just those medicines. I said, “This is too hard on his body and I don’t think we should continue.” The doctor said to me, “You are making the right decision.” I said to myself, “God gave me my kid to watch over. I am here to see that nothing happens to him that is bad. I am here to watch over his best interests, and I am not going to make him fight through this just because of my selfishness.”—Father who had decided to withdraw life support on behalf of his 17-year-old son dying of leukemia

**Key Points**
- Decision-making for parents facing the terminal illness of a child is, in many cases, extraordinarily difficult.
- Personal and professional caregivers can influence the extent to which patients and parents participate in end-of-life decision-making.
- Children and adolescents may need assistance making decisions based on their cognitive development, and each patient should be assessed as an individual to determine his or her competence.
- Preferences for treatment should be balanced between the child or adolescent patient and the caregiver or surrogate.
- Nurses have a professional responsibility to facilitate informed patient decisions at the end of life.

Deciding to end a child’s life, and involving a child in the decision to end his or her life, are startling phrases, but we in pediatric oncology participate in those considerations with parents, patients, and other members of the health care team as a part of providing the highest-quality care for the child or adolescent with incurable cancer. Participating in end-of-life decisions is life altering for the child or adolescent and for the family, but it can also be life altering for the health care provider. Clinical anecdotes suggest that the way in which patients, family members, and health care providers complete end-of-life decision-making can color all of their preceding treatment-related interactions, and may influence how well parents emotionally survive the dying and death of their child. The manner in which end-of-life decision-making processes are completed may also contribute to the survival of health care providers as compassionate and fully competent professionals.

Despite the significant immediate and longer-term impact of participating in end-of-life decision-making for a child or adolescent with incurable cancer, guidelines for making or for facilitating such decisions have only recently become available. Preparation for participating in end-of-life decision-making is rarely a formal part of a health care provider’s education and is rarely addressed in preceptoring or mentoring relationships. There is clearly a great need for information that can be used to further develop, test, and refine such guidelines. The purposes of this chapter are (1) to offer a review of the current literature (both clinical and research-based) on end-of-life decision-making in pediatrics, with a special emphasis on pediatric oncology, and (2) to offer guidelines for the use of health care professionals in assisting children, adolescents, their parents, and other health care professionals in making such decisions. Table 52–1 defines key terms used in this chapter.
Background

Advances in pediatric oncology have significantly increased the survival rates of patients during the past decade. The disease once thought to be universally fatal for children and adolescents is now viewed as a life-threatening, chronic illness that is potentially curable for many. However, cancer remains the leading disease-related cause of death in children and adolescents, as ultimately 25% to 33% will die of their disease. Indeed, approximately 2200 children and adolescents die of cancer in the United States on an annual basis.

With treatment advances come more treatment options and more treatment-related decisions for patients, their parents, and their healthcare providers. Although certain decisions, such as whether to have a permanent venous access device implanted and which type to use, are made early in treatment, parents and healthcare providers report that the most challenging decision-making in pediatric oncology occurs when efforts to cure the cancer have failed.

A few parents report that end-of-life decision-making was not complicated for them because they had already decided what they would do if their child's cancer did not respond to treatment. However, the majority of parents and healthcare providers involved in the decision process describe this time as extraordinarily difficult. They attribute the difficulty to multiple and complex factors that must be considered, including the differing preferences of those involved in the actual decision-making or affected by it, and to intense emotions at a time when the parents' energy is depleted.

Neonatal and Other Pediatric Specialties

End-of-life decision-making in pediatric oncology has been influenced by clinical and research reports from neonatal and other pediatric specialties and organizations. The growing commitment by professional associations to include pediatric patients and parents in end-of-life decisions marks a notable shift in care philosophy. Expectations that patients and their parents should be involved in these decisions have been formalized in policy statements of organizations such as the American Academy of Pediatrics, the American Nurses Association, the American Association of Critical Care Nurses, the United Hospital Fund in its report on end-of-life care in New York, the International Society of Pediatric Oncology (SIOP), and most recently from the Institute of Medicine. In these published statements, the recommended patient and parental involvement is described as participative and mutual with healthcare providers. Legislative rulings and legal decisions in some states and Canadian provinces support the participation of adolescents or mature minors in medical decision-making and in creating advance directives. It is likely that in the next decade, regulatory bodies such as the JCAHO will become involved in directing or evaluating end-of-life care, including patient and parental involvement in end-of-life decision-making. It is also likely that such involvement will be considered an indicator of the quality of end-of-life care and be linked to reimbursement for such care as is now being proposed for adult cancer patients.

The actual extent to which patients and parents participate in end-of-life decision-making varies and can be influenced by the personal and professional preferences of the healthcare provider. For example, the way the healthcare provider frames or words information about treatment options may influence the way a patient and family perceive the available alternatives. Some advocate that the physician should assume the final responsibility for the decision, whereas others believe that the parents should be the primary decision-makers. Yet another view, which is not espoused by many authors, is that the adolescent patient should be the primary decision-maker, with his or her parents serving as consultants. Even fewer sources advocate that children should be the primary decision-makers, but several advocate that children as young as 6 or 7 should be involved in the decision-making.

The available reports on end-of-life decision-making that involves parents and health care providers are predominantly from neonatal settings. End-of-life decisions in these settings often reflect the presenting condition of the infant. The decisions primarily considered include (1) limiting care, (2) withdrawing life-support, or (3) withholding life-support for infants who are extremely premature or have severe congenital abnormalities. Most reports describe the decision-making as

</tbody>
</table>
having been initiated when the intensivist determined that the infant had no chance for survival or no chance for quality of life. In most cases, parents agreed with the recommendations of the intensivist or the infant’s attending physician. These descriptive reports are based on review of medical records. No information was obtained from parents about the factors they considered when making an end-of-life decision on behalf of their infant.

Two notable exceptions exist. In the first, Able-Boon and colleagues interviewed parents and health care providers of seriously ill infants regarding medical decision-making and the provision of health care information. The parents emphasized their need and desire to be honestly informed of their child’s health status. They expressed special appreciation of health care professionals who drew pictures to convey technical information rather than relying only on words. Parents also expressed a strong need for information that is coordinated by the health care team so that it is not confusing or contradictory.

The second study that recorded the values of parents in end-of-life decisions is the grounded-theory study in which Rushton interviewed 31 parents of 20 hospitalized neonates with life-threatening congenital disorders about their decisions for or against implementing or continuing life-sustaining measures for their infants. Rushton concluded that the parents made these decisions based on their understanding of what it means to be a “good parent” for a neonate with a life-threatening congenital disorder. According to these parents, the characteristics of good parents for such neonates include putting the needs of the neonate first, not giving up, not taking the “easy” way out despite the self-sacrifice involved, and courage to pursue a “good” outcome for the child.

Reviews of the medical records of patients who have died in pediatric intensive care units (PICUs) show that withdrawal of life-support was chosen in 8% to 54% of cases, and that limitation of supportive care (described as not escalating care efforts but providing hydration and pain comfort measures) was chosen in 26% to 46% of cases. The wide range of these percentages may reflect cultural, ethnic, or religious differences: the lowest rate of withdrawal of life-support reported was from a PICU in Malaysia and the highest rates were from PICUs in Europe, the United States, and the United Kingdom. Even within a single PICU setting, decision-making can reflect cultural differences. For example, the report from the Malaysian setting noted that Muslim parents declined end-of-life options at significantly higher rates than did non-Muslim parents. Reports may also reflect the research method used. For example, Meyer and colleagues relied upon surveys completed by parents to assess parental perceptions of pain control, decision-making, and social supports during their child’s dying in a PICU. Parents reported that in most cases (n = 56; 90%), the physician initiated the end-of-life discussion but in approximately half of those cases, parents had been privately considering an end-of-life decision. Factors identified by parents as influencing their decision-making included concerns about their child’s quality of life, their child’s chance of getting better, their child’s pain or discomfort, advice of hospital staff, attitudes of hospital staff, and advice of friends or family members.

Several medical record reviews of end-of-life characteristics of children dying of cancer have been recently completed. In general, the majority of these children and adolescents die of progressive disease with a medical order not to resuscitate (DNR). These characteristics indicate the child’s likely death had been discussed with parents or family members. However, despite parental involvement in decision-making, the factors that influenced the decision-making and how the end-of-life discussions were initiated or facilitated were not included in the published reports.

**Participation of Children and Adolescents**

Children and adolescents have not routinely been involved in making end-of-life decisions on their own behalf, largely because of doubt on the part of parents and health care providers that the child or adolescent has sufficient understanding of the clinical situation. This doubt is based in part on adults’ belief that children and adolescents are unable to appraise their well-being and are unaware of their life goals and values. Buchanan and Brock described children who are 9 years or older as competent to make certain decisions, but they did not study children’s competence in end-of-life decision-making. The same authors also indicated that children of that age may be competent to make some decisions but not others, and that competence thus depends on the specific decision. According to Ariff and Groh, a child’s competence to make medical decisions is an ongoing developmental process that parallels other cognitive, moral, and emotional processes and is influenced by environment and by physical and mental illness. The capacity to make an end-of-life decision cannot be determined, then, on the basis of the child’s or adolescent’s competence in a different situation or decision. Instead, competence must be determined for each specific decision at a defined time point and under specific circumstances. Recent cognitive studies on adolescent decision-making indicate that although adolescents are able to make decisions, they may be unaware of all possible options or may be unable to identify all possible consequences of those options. Therefore, adolescents may need assistance in identifying, considering, and selecting end-of-life options.

Experiencing a life-threatening illness such as cancer and seeing others suffer and die from it may help a child to understand death and his or her own end-of-life circumstances. Although they acknowledged that the competence to participate in decision-making differs with age and cognitive abilities, Burns and Truog recommended that children and adolescents be involved early in the process of medical decision-making, including end-of-life decisions. In fact, Burns and Truog warned that if a child or adolescent is not involved early in the decision-making process, his or her ability to express an opinion may be lost before it can be exercised. Leikin theorized that adolescents who have been treated for cancer have a clearer idea of the burdens and benefits of treatment options that are most acceptable
to them. The ethical perspective is that adolescents have a conception of what is good for themselves. The treatment experience itself contributes to the adolescents’ abilities to participate in end-of-life decision-making.

Our combined clinical and research experiences have convinced us that, as a general rule, seriously ill patients aged 10 years and older are able to understand that they are participating in decisions about their cancer-related treatment and their lives, and are able to understand the options and the likely outcomes. Of course, some younger patients may also understand these issues and be competent to participate in end-of-life decisions, whereas some older patients may be less competent. Because of these very possible differences in understanding, each child needs to be individually assessed for his or her competence to participate. An assumption that a child is or is not competent to participate made without the assessment is not in the child’s best interest.

Others have provided compelling support for the involvement of younger children in end-of-life decision-making. Nitschke and colleagues reported that patients as young as 6 years of age participated in end-of-life discussions in their pediatric oncology treatment setting. They described care conferences held with 43 families over a 6-year period in which children and adolescents with end-stage cancer, and their families, participated in discussions of therapeutic options, disease progression, lack of effective therapies, improbability of cure, and imminent death. The patients (who were 6 to 20 years of age) and their parents were offered the choice of Phase II investigational drugs or supportive care. According to this report, it was the patients who most frequently made the final decision. Fourteen chose further chemotherapy, 28 chose supportive care only, and 1 made no decision. Nitschke and colleagues also noted that patients younger than age 9 understood that they were going to die soon of their disease. The authors concluded that children with cancer do have an advanced understanding of death and recommended that children as young as 5 years of age have the capacity to make decisions about whether to continue therapy. This team did not investigate the specific factors considered by the patients, parents, and health care providers and did not describe ways in which providers may have attempted to facilitate patient and parent decision-making.

A health care team member who has established a relationship of trust with the child or adolescent and who has observed the child or adolescent in various challenging clinical situations is likely to be the best judge of competence in end-of-life decision-making. However, before initiating this assessment, the health care team should discuss the purpose and process of the assessment, first as a group and then with the patient’s parent or parents, and identify any areas of actual or potential disagreement between the team and the parents. Disagreements should be openly discussed, and participants should be allowed sufficient time to weigh the issues—another reason for initiating the end-of-life discussions in a timely manner. After the team and the parents agree on the intent and timing of the competence assessment, the team member, parent(s), and child or adolescent choose the location for the discussion. Most children younger than 11 years of age prefer to have their parents present for this discussion.

Determining the child or adolescent’s competence requires establishing whether he or she understands the seriousness of the medical condition and understands that a decision point is at hand. If asked to explain the seriousness of the situation, the child or adolescent will use words or describe events that have personal, symbolic, or literal meaning. The health care team can then use these same words to communicate with the patient about decision-making. Throughout the assessment, the child or adolescent will need reassurance from the health care team member that the serious situation is not the fault of the child or adolescent. The child or adolescent must also be able to indicate an understanding of the choices, including the potential consequences of each. In addition, the child or adolescent must show an understanding of how each choice made now could change future options. As McCabe and colleagues emphasized, the health care team member conducting the assessment must ensure that the child or adolescent does not feel coerced to make a certain choice. The team member should also ensure that the child or adolescent has access to the information needed to make a competent decision. The team member needs to allow repeated opportunities for the child or adolescent to review the options and discuss concerns and to do so in a manner that is not rushed, and to provide different mechanisms (verbal, written, drawing) to facilitate expression of concerns or preferences. It is especially important that the team member assess to what extent the child or adolescent wants to be included in the decision-making. That preference should be honored regardless of the personal preferences of team members.

Our experience is that children (some as young as 7 years of age) have definite preferences regarding whether to participate in a Phase I clinical trial. Preferences most commonly reflect a desire to be home, to play with a sibling or a friend, or to not feel sickly. Preferences regarding DNR status, although quite firmly expressed by some adolescents, tend to require more patient contemplation time. By the time this type of end-of-life decision-making needs to be considered, the members of the health care team are very familiar with the child and the family and already have established a style of interacting. However, it is generally useful to preface the assessment of patient preference with a statement that conveys the important nature of what is about to be said, such as, “May I ask you to be quite serious with me for a few moments? I want to tell you something important about your [insert here the term used by the child when referring to the illness]. And I want you to tell me something, too.” If the child conveys an inability to be serious at that moment, the team member needs to clarify whether that means the child only wants the “serious and important” topics to be discussed with the child’s family, or if it means the child wants to try to be serious at a later time. Clinicians are encouraged to allow repeated opportunities for the child or adolescent to review the care options or concerns, to provide a variety of mechanisms to facilitate the child’s
expressions (such as using words, drawing or writing), and to do so in a manner that is not rushed.

**Competence of Surrogates**

Concern about patients’ competence to participate in end-of-life decisions, although valid, may sometimes be exaggerated. As Levetown and Carter,61 wrote, it is relatively easy to usurp the autonomy of children and adolescents in end-of-life decision-making. This threat lends special importance to the use of guidelines for making end-of-life decisions. Guidelines could serve as formal reminders to health care professionals to consider the preferences of children and adolescents to the extent that is possible or advisable. Of equal or greater concern is the competence of parents and health care providers to make such decisions on behalf of the child or adolescent. Making these decisions competently requires an understanding of their own values, the patient’s values and goals, the treatment options, the likely outcome of each option, and the nature of the life-threatening illness. This imposes a short-term and a longer-term burden of unknown proportions on the parents and the health care providers.

There are few empirically based or theoretically based guidelines for involving children, adolescents, or their parents in end-of-life decisions. Instead, it is generally assumed that children younger than age 10 years are not competent to participate in such decision-making and that their parents are both competent and attentive to the best interests of their child.20,31,58 This assumption is crucial, because it tends to ensure that end-of-life decisions are made for seriously ill children and adolescents by their parents and health care professionals. Legal rulings and common health care practices support the role of parents as surrogates in this circumstance; it is rarely challenged, and health care providers or others replace parental authority only in exceptional circumstances.58 To feel competent, to be competent, and to be satisfied with their performance as surrogate decision-makers, parents and health care providers need opportunities to exchange information about the child’s preferences, the family’s preferences, the child’s chances of survival, the progression of the disease, and the intensity and intrusiveness of life-extending interventions and the likelihood of their effectiveness (including length of time gained). They also need to reflect on previous efforts to achieve cure and to question previous decisions. Competence of surrogates may also be affected by their realization of the likelihood of their child not surviving cancer. In one retrospective, descriptive study that included parent interviews and review of medical records, it was identified that physicians knew up to a year before the parents that the child would not survive.63 Participating in end-of-life care planning is unlikely if the reality of the child’s death is not yet in the parents’ or surrogates’ awareness. Competence of surrogate participation is also influenced by the challenges faced by health care providers when trying to accurately predict timing of the dying.64 However, only in a limited number of cases is the child’s dying unexpected. Because of that, some degree of planning for preferred model of end-of-life care (home, home with hospice, hospital, hospital with hospice) is possible.65-66 Matching the surrogates’ preferences for end-of-life care might contribute to decreasing the morbidity of bereaved survivors.

**Participation of Patients and Parents**

Previous studies indicate that the more informed parents become about their seriously ill child’s condition, the more they are able to participate in making decisions and advocating for their child.67,68 Parents report that information is most helpful when it is provided gradually and repeatedly.69 Stevens70 recommends that parents be allowed to make tape recordings or bring friends or family members to the treatment-related discussions to help them later recall the details of the discussion. Other investigators suggest that parents differ in how much detailed information they desire71 and in how much they want to participate in the actual decision-making72,73 during periods of crisis in their child’s illness. However, parental preferences about participation in end-of-life decision-making have not been well studied.

In an international feasibility study, parents from pediatric oncology settings in Australia, Hong Kong, and the United States were interviewed about their decision-making on behalf of their ill child. There were clear differences among the countries in parental preference for involvement in decision-making. Mothers in Hong Kong were reluctant to participate in end-of-life decisions because of either their gender (“Women cannot make these decisions.”) or their lack of expert knowledge (“I am only the mother. The doctor is the expert and he should decide.”).74 It remains unknown whether these parental preferences change between diagnosis and end of life. Regardless of their preference, all parents need reassurance from the health care team that their child’s condition is not their fault.70

The factors that parents consider at decision points in the treatment of their seriously ill child have only recently been studied. Using a phenomenological approach, Kirschbaum75 interviewed 20 parents of children who had died in the previous 6 to 12 months. The parents had all made life-support decisions on behalf of their ill child. A variety of diagnoses were represented, including trauma, cancer, septic shock, liver failure, and congestive heart disease. Nine factors were identified as having influenced the parental decisions: (1) wanting life as the principal good for their child, (2) avoiding suffering and pain, (3) considering current and future quality of life, (4) respecting the individuality of the child, (5) defining and redefining the family, (6) having spiritual beliefs and explanations, (7) believing in natural or biological explanations, (8) considering the child’s unique personality, and (9) having a favorable view of technology in health care.
In a retrospective study that conducted telephone interviews with 39 parents of 37 pediatric oncology patients who had died in the previous 6 to 24 months, Hinds and colleagues were able to identify the factors most frequently considered by parents in end-of-life decision-making. The end-of-life decisions that were reported most frequently by these parents were choosing between a Phase I drug study and no further treatment (n = 14), maintaining or withdrawing life support (n = 11), and giving more chemotherapy or ending treatment (n = 8). The factor most considered in the parents’ decision-making was “information received from health care professionals.” This information included facts, explanations, and opinions about their child’s disease status, likelihood of survival, and complexities of continued care. Other factors parents frequently reported were “feeling supported by and trusting of the staff,” which reflected the parents’ sense that the health care team listened and responded to their or their child’s concerns and respected the parents’ decisions, and “making decisions together with my child.” This factor reflected the parents’ comfort in having known and respected their child’s wishes.

The parents also completed a 15-item questionnaire about the importance of each factor considered in their decision-making.

| Table 52–2 |
| Guidelines for the Health Care Team to Use in Assisting Parents with End-of-Life Decision Making |
| 1. At the time of diagnosis and throughout treatment, actively seek opportunities to provide information to the parent about treatment and the patient’s response to treatment. |
| 2. At the time of diagnosis and throughout treatment, involve the parent in treatment-related discussions and decision-making. Be available to discuss and rediscuss decisions and related concerns. |
| 3. Encourage parents to talk with parents of other pediatric oncology patients. |
| 4. Verbally and nonverbally reassure the parents that they are “good” parents who are committed to the well-being of their child. |
| 5. Give assurances that everything that can be done to help the patient is being done and being done well. |
| 6. As the child’s disease progresses, provide clear verbal (and written, if desired by the parent) explanations of the child’s status. |
| 7. Inform parents of treatment options as they become available in the treating institution or elsewhere. |
| 8. Include more than one health care team member in end-of-life discussions with the parents. |
| 9. When discussing end-of-life options with parents, |
| a. Strongly emphasize the team’s commitment to the patient’s comfort and to providing expert care at all times. |
| b. Offer professional recommendations. |
| c. Describe how their child is likely to respond to each option (the child’s physical appearance, ability to communicate, etc.). |
| d. Give information about other support resources (ethics committees, social services, other health care professionals, etc.). |
| 10. When discussing end-of-life options with parents, anticipate |
| a. Parents’ vacillation between certainty and uncertainty about the decision. |
| b. Parents’ need for clarification and additional information to resolve their uncertainties. |
| c. Parent’s need for practical information about ways to explain the end-of-life decision to other family members. |
| d. Being asked to give personal advice. |
| 11. Allow parents private time to consider the options. |
| 12. Maintain sensitivity to any specific ethnic, cultural, or religious preferences during the terminal stage. |
| 13. Convey respect for the parents’ right to change decisions, when clinically feasible. |
| 14. Demonstrate commitment to maintaining the child’s comfort and dignity, and to affirming the parents’ role. |
| 15. Do not question the parents’ decision after it has been made. |
The parents rated eight items as “very important” at least 50% of the time. The highest rated factors included “recommendations received from health care professionals,” “things my child had said about continuing or not continuing treatment,” “information received from health care professionals,” “my child’s breathing problems,” and “sensing that my child was no longer himself [herself].” These findings clearly indicate that information and recommendations received from health care professionals are very important to parents who are making end-of-life decisions on behalf of their child, as is feeling certain of their child’s desires about treatment.

The same research team has prospectively studied end-of-life decision-making by conducting interviews of parents, physicians, and, when possible, the children or adolescents with incurable disease who had participated in making an end-of-life decision within the past week. The same factors noted in the retrospective study—related to trust, support, information, and advice—were also identified in the prospective study. In addition, parents cited these factors: wishing for the child’s survival, reassuring themselves of the correctness of their decisions, questioning certain statements or behaviors of health care professionals, and making decisions that would allow them to maintain communication with their dying child for as long as possible (Table 52–2).

**CASE STUDY**

**A Decision Agreement Between Parents and the Health Care Team**

A 12-month-old infant girl has been treated for an aggressive form of leukemia. It is clear that the disease is not responding to chemotherapy. The patient was transferred to the PICU when she began to experience respiratory distress. Initially, oxygen was administered by simple mask, but her breathing difficulties persisted and became more evident within a few hours. The possibility of endotracheal intubation was first discussed among the health care team members and then with the parents. During the meeting with the parents, the current symptoms of the little girl were discussed, the current disease status and its unresponsiveness to treatment were reviewed, and options of intubating or not intubating were considered. The parents then discussed the options privately with each other and in less than 30 minutes reached the decision that ventilatory support not be a part of their daughter’s medical care. The parents said that knowing that their daughter was not going to be cured of the leukemia and understanding that the ventilator would help reduce their daughter’s respiratory distress but not the leukemia were both factors that assisted them in making the decision. They credited their discussions with the doctors as key: “From the discussion we had with the doctors, we felt if it came to that point, the only reason for using a ventilator would be just to keep her breathing.” An additional factor identified by the parents as influencing their decision-making was support from the health care team. “Chaplain X and Dr. Y were real patient with us and understood the situation that we were in and did not seem to put pressure one way or another, or seem to think that we were making the wrong decision one way or another . . . they told us the decision was actually ours. They let us know that, but they were supportive and also gave us their opinions.”

**CASE STUDY**

**Disagreement**

An adolescent with incurable cancer had been hospitalized for 3 weeks, the past 8 days in the ICU. His physical deterioration and suffering had created anguish in his father and in the health care team. The attending physician discussed with the father the likelihood of the adolescent having a cardiac arrest, described the actions the team would take for a full resuscitation, as well as the varying levels of resuscitation approved by the treatment setting, which included a DNR option, and asked the father to express his preferences regarding resuscitation. The father initially chose the DNR status for his son and completed all of the official paperwork to implement that decision. During the next 12 hours, the father actively solicited from nursing and medical staff their definitions of DNR. He then contacted the attending physician to rescind his decision, choosing instead to have a full resuscitation order in place. He explained his decision change as, “When I saw that the nurses and doctors did not all define resuscitation in the same way, I decided that I would not leave that in their hands. I am my son’s father and I will be his father to the end.” This new decision was enacted and over the next 4 days, the young patient showed clear signs of dying. His father stayed with him in the ICU and witnessed the changes in his son’s physical appearance. He began commenting on those changes and on his son’s obvious suffering. Two hours before his son’s death, the father told the nurse that he did not want his son to be resuscitated. This information was immediately conveyed to the health care team and a brief discussion with the physician, father, and nurse was convened to affirm this decision.

**CASE STUDY**

**Reluctant Agreement Between Adolescent, Parents, and Health Care Team**

A 15-year-old male adolescent and former star pitcher for his high school baseball team had been aggressively treated for Ewing’s sarcoma for 13 months. The primary site was his upper right arm, his pitching arm. A limb-sparing procedure had been successfully completed but his disease had recurred and rapidly progressed. His pain was exceedingly difficult to manage and he openly spoke of his readiness to die. His
mother continued to press for treatment options. They were advised of an open Phase I trial and were made aware of the experimental agent in the trial, and the toxicity-finding purpose of the trial, but were also advised by the treating team to consider only symptom management care efforts. The mother strongly urged her son to enroll in the Phase I trial. In a private meeting with one of his nurses, the adolescent confirmed that his personal preference was to go home to die but that he had not told his mother about that because he knew she was not ready yet for his death. The nurse asked for his permission to advocate on his behalf with his mother, but he thoughtfully declined, stating that enrolling in the trial was his final gift to his mother, a gift that he wanted very much to give her. With personal regret, the nurse accepted his choice without discussion with his mother and the adolescent enrolled in the trial and completed three courses before his disease progressed. Although he continued to experience pain during those three courses, he remained certain of the importance of his decision because of its benefit for his mother.

Twenty patients participated in individual interviews about the end-of-life decision they had made. The factors most frequently considered in their decisions included “being influenced by relationships with others,” “information from my doctor or my parents,” “wanting to be done with treatment,” and “worrying about my family.” These factors convey the interconnectedness between children or adolescents with incurable diseases and their families and health care providers. All are affected by the decision-making process and the outcomes of the decision. This interconnectedness among the seriously ill child or adolescent, the family, and the health care providers contributes to more agreements on end-of-life decisions than disagreements. Although rare, disagreements between the patient and parent, or between parents and health care providers, do occur and are especially difficult for all involved. Disagreeing with a health care professional who is deemed essential for their child’s well-being and with whom a care alliance is desired is at best troubling for parents, but at worst, disruptive to relationships and problem solving. When circumstances exist that allow a delay in the contested decision-making, a consultation with an ethicist or ethics board can facilitate decision-making. Involving the family, the patient who is deemed competent to participate in end-of-life decision-making, and the health care team in the same meeting with the ethicist or ethics board is particularly helpful, as all perspectives can be considered. When a family and a health care team do not have agreement, special measures must be initiated by the team leaders to support team members in their efforts to continue to deliver excellent care to the patient and family. Measures can include brief meetings with an esteemed institutional leader who openly acknowledges the sizeable difficulty that the team is facing, having information-sharing or cathartic sessions with the ethicist, and developing strategies for handling similar future difficulties. Likewise, similar support measures need to be implemented for the family. In addition, regular opportunities to interact with the health care team (such as care conferences) need to be established so that trust between the family and team can be fostered.

**Case Study**

*Involving an Ethicist to Assist a Team in Anticipation of, During, or After an End-of-Life Decision*

A 7-year-old boy had a second recurrence of acute lymphoblastic leukemia. His leukemia was first diagnosed when he was 19 months old. The first recurrence occurred less than a year after completing the 3-year treatment protocol, and the second recurrence occurred 8 months after completing the treatment for relapsed leukemia. As his mother pointed out to the treating team, her son had had very few months in his life of feeling healthy. She conveyed reluctance to continue any curative efforts, preferring instead to have her son discharged from the inpatient unit so that she could take him home. The attending physician, an internationally recognized expert in the treatment of leukemia, strongly disagreed with the mother’s stated preference and offered her information on the likelihood of cure (admittedly low) and emphasized his desire to continue curative efforts. When the mother firmly declined the option of further treatment, the physician told the mother that he considered the discharge to be “against medical orders” and noted that in the medical record. A nurse on the team later approached the physician and proposed a meeting with the team and an ethicist to discuss the decision. The physician agreed and the full team met a week later with an ethicist. The physician honestly acknowledged his sadness about the child’s incurable disease, his liking of the child, and his concern that because the mother disagreed with his recommendation of further treatment, the health care team might think less of him as a physician. The team and the ethicist reacted with surprise at the last admission and conveyed instead their strong respect for him and his efforts to be a good doctor and for the mother’s efforts to be a good parent. The physician offered to write a letter to the mother expressing the team’s support of her and her child and that the child would always have complete access to all of the care setting’s resources. The mother telephoned the physician after receiving the letter to express her relief. Three weeks later, the mother brought her son to the hospital to die.

**Factors Considered by Health Care Providers**

The factors considered by health care professionals in end-of-life decision-making on behalf of children and adolescents reveal important similarities and differences between nurses and physicians. Current reports indicate that nurses are more likely to reflect on the moral balance of the decision, that is, the goodness or lack thereof of extending a child’s life if doing so
also extends or increases the child's suffering, whereas physicians first consider whether the child's life can be saved. This difference can create tension within the health care team and merits discussion by the team members. Nurses and physicians also identified a factor they both consider frequently in end-of-life decision-making for pediatric oncology patients: "respecting the patient's and family's preferences." This factor reflected the health care professionals' efforts to inform the patient and family of all options and then to respect the choice they made. In a survey completed by 21 health care professionals in pediatric oncology (16 physicians, 3 nurses, and 2 chaplains) regarding end-of-life decisions for patients with incurable cancer, the factors rated as most important included "discussions with the family of the patient," "thinking the patient would never get any better," "the belief that nothing else could help the patient," and "things the patient had said about continuing or not continuing treatment." Most of the participating health care professionals also indicated that they did not make end-of-life decisions alone but sought the input of other team members.

Strategies for Facilitating Child, Adolescent, and Parent Involvement

End-of-life decision-making is a process that very likely begins at the time of diagnosis, when the patient and the parents are exposed to the seriousness of the illness, the possible risks of treatment, and the uncertainty of short-term and long-term treatment outcomes. When faced with the actual decision-making, a few parents and patients express a preference seemingly without hesitation or anguish. They are likely to have gained an earlier understanding of the situation; often, patients and parents who observe others undergoing end-of-life experiences begin to reflect on their own lives. More often, however, patients and parents require time to think after becoming aware of the impending decision point and treatment options. In both the briefer and longer contemplation periods, the decision-making capability evolves as treatment continues and understanding of the patient's situation increases. As noted in the American Academy of Pediatrics guidelines on forgoing life-sustaining treatment, end-of-life decision-making is not a single event or one well-defined point in time.

It is essential that health care providers realize that the end-of-life decision-making process begins early in treatment and evolves with each interaction between the provider, the patient, and the parent, and with each observation of or encounter with other seriously ill patients and their parents (Figure 52–1). Each interaction provides an opportunity for the health care provider to build the patient's and family's trust in him or her as a source of information and support and as a care expert who can be relied on to do what is best for the patient. Each interaction is also an opportunity for the provider to facilitate parents' efforts to function fully as parents—a role that becomes increasingly uncertain as parents deal with unfamiliar decisions. Feeling competent in their parenthood is especially crucial to parents who face end-of-life decisions on behalf of their child. Believing that they have acted as "good parents" in such a situation is likely to be very important to their emotional recovery from the dying and death of their child.

Decision-making by patients and parents is influenced not only by their interactions with the health care team but also by the impressions they form through observations of and encounters with other patients and families in the care setting. As patients and parents learn about the treatment experiences and the positive or negative outcomes of other patients, they

---

**Figure 52–1.** The interaction and experiences of pediatric oncology patients, their parents, and the members of their health care team (HCT) from the point of diagnosis forward that influences end-of-life decision-making.
contemplate what it would be like to experience those situations themselves. A second type of personal experience that prompts this kind of reflection is an unexpected negative response to treatment, such as an adverse reaction or even disease progression, after positive responses. When patients and parents feel well informed by health care team members about disease response to treatment and are routinely involved in treatment discussions and other decisions, they are being prepared for end-of-life decision-making, should it become necessary.

A third experience that prepares the patient and parents for end-of-life decision-making is the patient’s experience of suffering and the parent’s experience of witnessing that suffering and being unable to adequately relieve it. In our research with parents of children and adolescents who are experiencing a first or second recurrence of cancer, parents and guardians are more likely to contemplate ending curative efforts when they see their child in pain, unable to enjoy favorite activities, places, and people, or unable to find comfort.71,73 Parents may react to the same experiences in different—even opposite—ways. The mother of a child treated for acute lymphocytic leukemia wrote in her guide for parents, friends, and health care providers that an end-of-life decision is an “intensely personal decision.”78 Some parents seek to exhaust all possible treatments, whereas others hope only for sufficient time to prepare themselves and their child for the dying and death. A study by Hollen and Brickle79 suggested that the socioeconomic status of parents of well adolescents helps to predict the quality of the parents’ decision-making about their teenage children. However, no similar data are available that identify relationships between characteristics of parents whose child is seriously ill and their end-of-life decisions on behalf of their child.

The Nurse’s Role

The American Nurses Association’s Position Statement on Nursing and the Patient Self-Determination Act13 asserts that nurses have a professional responsibility to facilitate informed decision-making by patients about end-of-life options. The statement does not specify patient age, but other wording, such as that describing the nurse’s responsibility for knowing state laws about advance directives, suggests that the statement is oriented toward adult patients. The document also asserts that the nurse is responsible for ensuring that advance directives are current and reflect the patient’s choices. The ANA makes equally explicit assertions about the nurse’s role in its position statement “Nursing Care and Do-Not-Resuscitate Decisions.”13 That position statement urges nurses to assume principal responsibility for ensuring that competent patients’ preferences regarding resuscitation are honored, even if those preferences conflict with those of other health care professionals and family members. Nurses are further urged to facilitate explicit discussions of the resuscitation order with the patient, family members, and health care team, and to document the decisions clearly.

Several general studies about how nurses, physicians, and other health care team members perceive end-of-life decision-making have revealed differences in role responsibilities and interpretations of care priorities.40,80–84 These differences contribute to tension among team members. It is important that team members be aware of official statements issued by each discipline’s professional association about role expectations.

*When considering whether the patient should be present during such discussions, evaluate the developmental stage of the patient and the severity of illness and symptoms at the time of the discussion.
For example, the Guidelines on Forgoing Life-Sustaining Medical Treatment issued by the American Academy of Pediatrics indicates that physicians are expected to provide adequate information to patients, parents, and “other appropriate decision makers” about therapeutic options and their risks, discomforts, adverse effects, projected financial costs, potential benefits, and likelihood of success. In addition, physicians are expected to offer advice about which option to choose and to

elicit questions from the patients and parents. Nurses should openly discuss expectations and team functions with other team members (Table 52–3) to prevent misunderstanding or disappointment about their perceived roles.

Guidelines for End-of-Life Decision-making in Pediatrics

End-of-life decision-making for children and adolescents who have been seriously and chronically ill necessitates consistent and careful attention to their most meaningful relationships. The relationships of obvious importance are the relationship of child or adolescent with self and with family. Less obvious but also meaningful relationships are those between the patient and the health care professionals, and between the family and health care professionals (those who provide care for the child or adolescent or for the family). Because of the importance of these relationships in end-of-life decision-making, separate (although overlapping) guidelines are provided addressing how members of the health care team can assist parents, patients (Table 52–4), and each other in making end-of-life decisions. The overlap in the guidelines reflects the parallel, and at times interacting, decision-making processes experienced by children, adolescents, and their parents. Health care professionals will be most effective in implementing these guidelines if they first reflect on their feelings and concerns about the dying and death of children and adolescents and about participating in end-of-life decision-making. Research findings to date consistently indicate that when the child or adolescent participates as fully as possible in end-of-life decision-making, parents and health care providers are more certain and more comfortable about the decision that is made. Their belief that the decision reflects the child’s or adolescent’s preferences helps parents and health care providers to make the decision and to recover emotionally from this painful experience.

Key Points
- Palliative care in the neonatal intensive care unit (NICU) is as much a part of family-centered care as any other aspect of care. Palliative care gives nurses the opportunity to do what nurses do best: nurture and care for the whole infant and family unit at a time of tremendous stress. It is the most intimate time that one can share with a family.
- Palliative care incorporates symptom management for the infant, and emotional, psychosocial, and spiritual support for the infant and family members. Family is defined by the parents and may include other children as well as grandparents and other close family members. The support is always provided in a cultural and developmental manner appropriate for each person. Palliative care is provided when a condition is life threatening and may or may not result in death.
- Palliative care is the antithesis of what most professionals and families think about within the context of infant care. The primary focus of infant care is and should be life-prolonging care. Yet palliative and end-of-life (EOL) care are a part of neonatal nursing. In 2001 there were 27,568 infant deaths in the United States, with an infant mortality rate of 6.8 per 1000 live births. Neonatal mortality accounts for about 60% of these infant deaths. Thus it is obvious that the death of a newborn can be a part of the nurse’s sphere of practice and requires that the nurse develop competencies in providing supportive palliative care, which may lead to a peaceful death.

American society does not have a word for a parent who has lost a child—another challenge for the nurse. For example, the term “widow” is used for the surviving female spouse, but what do we call the surviving parent? There is no term, but the loss in many cases is more profound than a spousal loss, only because western culture no longer expects children to die before their parents. In fact, the role of parent is often viewed as gone when a baby dies. One nurse, prepared in palliative care, responded to a grieving mother whose baby was not likely to survive to term, “You are a mother now, and you will always be a mother, regardless of whether or not your baby survives. You have a baby and that makes you a mother.” While this was comforting to the mother, it points out the lack of good alternative language to describe a parent who has lost a child.

Other cultures may have words or strategies to support parents who have lost an infant, but American culture labels the person a bereaved parent and talks about another child in the parent’s future or another child the parent may have.

This chapter presents the core values of palliative care within the context of providing culturally appropriate, individualized, family-centered developmental care (IFCDC) for infants receiving care in the NICU environment. The following case study will act as an exemplar of neonatal/pediatric palliative care.

To illustrate use of palliative care with the neonatal population, the following case study was supplied by team members from the Footprints Program (Continuity of Care Palliative Care Program), SSM Cardinal Glennon Children’s Hospital, St. Louis, MO (used with permission).

Case Study
Christian, a Newborn Patient with Holoprosencephaly

March 8, 2001: We arrived at the hospital about 7 AM. Within an hour we were told, “You’re going to have a baby today!” During the next 6 hours, everything went spiraling downward.
My doctor discovered I had hemolysis, elevated liver enzyme levels, low platelet count (HELLP) syndrome (my blood wasn’t clotting and my liver and kidneys were shutting down). I was prepped for an emergency cesarean section and wheeled into the operating room. My husband, Matt, waited anxiously in the hallway for news of our new baby and my health. I can only imagine the fear he felt as a group of nurses carrying a small bundle rushed out of the operating room. I awoke in the recovery room and asked to see my husband and child. About 30 minutes later, Matt came into the room and bravely told me about our little boy and his problems. Christian was being transferred to SSM Cardinal Glennon Children’s Hospital in St. Louis where he could be better evaluated. “Can I see him before he goes?” was all I could ask.

The transport team brought in a tiny 5-pound, 3-ounce, 17-inch baby boy with IVs, an oxygen mask, and monitors. Christian was handed to me and I cradled my son in my arms. Matt said this was the proudest moment of his life. We had our first family photo and handed Christian back to the team after so few minutes. We were supposed to be celebrating the birth of our child but instead were overcome with worry, grief, and fear.

Over the next few days, we talked with many specialists in the NICU at Cardinal Glennon. Christian was diagnosed with holoprosencephaly, a condition in which the brain does not separate into two hemispheres. Christian also had cleft palate, cleft lip, and blindness, and was in constant seizure. We were told he would most likely not live beyond 2 weeks to 2 months, or, if we were lucky, 2 years.

After discussion, we determined we wanted Christian to experience every moment he could while he was alive. First and foremost, we wanted to take him home. Our NICU staff identified a program in the hospital that could help us make that desire a reality. They referred us to the Footprints Program (SSM Cardinal Glennon Hospital, St. Louis, MO); which cares for children with life-threatening and terminal illnesses. The Footprints staff identified a continuity physician who would direct Christian’s care and gathered a team of our physicians, nurses, and chaplains to meet with Matt and me and our family members to make plans for Christian’s eventual homecoming. Together, we identified our goals and our fears and, with help from the team, developed a plan of care for our son that would give him the best quality of life. While the NICU staff taught us how to care for Christian’s basic physical needs, the Footprints staff contacted all of the care providers who would be involved in his care once he was home...home health/hospice providers and the emergency medical services (EMS) community in our town. Because we expressed fear at what others might think if Christian died at home so soon after birth, the staff also contacted our local police department to let them know that Christian was seriously ill and not expected to live. A plan was in place! But we had yet to learn that Christian was the strongest person we had ever met!

Christian came home after 13 days in the NICU, and while scary, each day became easier. We focused on Christian and with encouragement from the NICU and Footprints teams made memories that would last forever. We took him outside to experience the wind in his hair, the sun on his face, and cold water on his feet. The next few months brought many changes. We needed to replace the feeding tube with a g-tube. We heard him cry for the first time, and while sad, it also made us smile. We visited the neurologist, and the doctor stated Christian was a “completely different baby than in the NICU.” Christian was responding to his surroundings. He became a hospice dropout at the age of 6 months!

The Footprints team stayed very connected with follow-up phone conversations on a regular basis, encouraging us as Christian changed to redefine our goals and our hopes. We knew they were available to answer our questions at any time and always felt supported. We continued to give our son all of life’s experiences—trick-or-treating (we ate the candy), snow on his face, and time in church. We were allowed to be Christian’s parents and to leave some of the other more technical details to our care team. At a year, we met with the Footprints team and our physicians to reevaluate Christian’s care plan, still focusing on the best quality of life we could give him, while keeping him with us as long as possible. We were also more prepared at that time to discuss arrangements for the time of Christian’s death. Once again, we had a plan and all caregivers were notified of the revisions and new additions.

In spite of several serious cases of pneumonia, Christian celebrated his 2nd birthday, and he became a big brother. He lived to be 2 years, 8 months, and 2 days. We were able to hold him in our arms as his little body just wore out. His last moments were as we had wished, peaceful and at home with us. We are so glad we had a care plan in place. There were no arguments or questions. Arrangements basically fell into place. Our care plans focused on Christian’s quality of life, and helped us to focus on dignity at the time of his death. We were able to celebrate the life of our son each step of the way. The Footprints team continues to support us with phone calls and visits and is always available to help with any questions or issues we might still have.

Christian taught us about strength and hope, and what was truly important in life—love. Our lives are better—we are better—because Christian is a part of our family.

—Jennifer Anderson, Christian’s Mom

Case Summary

We wanted Christian to experience every moment he could while he was alive.

Stated by Christian’s mother, this goal is the essence of the best in neonatal palliative care. No one could predict the length of his short life. For this family, his life was much longer than the
predicted 2 weeks to 2 months. Thus, his life illustrates that neonatal palliative care must be planned in such a way as to meet the needs of the patient and family for whatever period of life the neonate has, in whatever environment that life is lived. The principles are the same regardless of the length or location of that life. Plan for death, support the parents, provide the best possible symptom relief for the neonate, honor the parents wishes, and at all times honor the life—while at the same time not denying that death is likely to occur prior to a usual lifetime of 70-plus years. With neonatal palliative care, perhaps even more so than adult palliative care, the critical element is for the health care team and family to know the goals for the brief life and not just about advance care planning choices. And as his mother described—create memories of that life lived.

Excellence in palliative care can provide a positive outcome for the family and neonate even though the neonate cannot be cured. Health care professionals can do much to make a difference. Let it never be said that “there is nothing we can do.”

Palliative and end-of-life (EOL) care is the antithesis of what most of us expect to provide to newborns. Yet this is a vital part of our neonatal skills. It is a privilege to be a part of birth and death, but it takes a professional who is adept at communicating, anticipating, and nurturing a family under tremendous grief to participate. It also requires acceptance that grief work extends to the health professional, and we must care for ourselves as we care for others.

### Core Principles and Philosophy of Care

As this case study points out, a shared interdisciplinary team approach, including the parents as part of the team, can make all the difference in how the end of life is experienced. As with any plan, there must be a shared understanding of how care is to be provided. Just as businesses and other enterprises have moved towards having a mission, vision, and core values or principles, so has palliative care. The mission, for example, of this text is to advance the knowledge of health professionals about palliative and EOL care. The vision of this book is that this text is to advance the knowledge of health professionals about palliative and EOL care. These core principles are the drivers of palliative care.

1. **Good Medical Treatment**

   • Your baby will have the best of medical treatment and nursing care, aiming to prevent illness or disease progression, to promote survival, to encourage growth and development, to prevent known potential complications, and to ensure comfort.
   • Your baby will be offered proven diagnoses and treatment strategies that inhibit disease progression, enhance quality of life, and promote living fully even though a condition is life threatening.
   • We will use medical and nursing interventions that are in accord with best available standards of care and practice and consistent with your wishes and values.

2. **Never Overwhelmed by Symptoms**

   • Your baby will never have to endure overwhelming pain, severe breathing distress, or other overwhelming symptoms.
   • We will anticipate and prevent symptoms when possible. When symptoms occur, we will evaluate and address symptoms promptly.
   • We will treat severe symptoms, such as breathing difficulty as emergencies.
• We will use sedation when necessary to relieve symptoms that cannot be relieved in other ways near the end of life.

3. Continuity, Coordination, and Comprehensiveness
• Your baby’s care will be continuous, comprehensive, and coordinated.
• We will be sure knowledgeable, caring, health care professionals care for your baby.
• We will make sure your baby and your family can count on an appropriate and timely response to needs.
• We will make sure you can count on access to health care professionals to answer questions.
• We will try to minimize transitions among services, settings, and personnel; and when transitions are necessary, we will make sure they go smoothly.

4. Well-prepared, No Surprises
• You and your family will be prepared for everything that is likely to happen in the course of your baby’s illness.
• We will let you know what to expect if the illness worsens—and what we expect of you.
• We will provide you with training and access to the supplies needed to handle your baby’s predictable care needs.

5. Customize Care, Reflecting Your Preferences
• Your wishes will be sought and respected and followed whenever possible.
• We will tell you about the alternatives for care and services for your baby, and support you in making choices that matter to you.
• If you wish, we will help your child to live out the end of life at home.

6. Consideration for Patient and Family Resources (Financial, Emotional, and Practical)
• We will help you to consider your family’s personal and financial resources, and we will respect your choices about their use.
• We will inform families about services available in the community and the costs of those services.
• We will discuss and address the concerns of family caregivers. When appropriate, we will make respite, volunteer, and home aide care part of the care plan.
• We will support families before, during, and after a loved one’s death.

7. Make the Best of Every Day
• We will do all we can to see that your baby and your family will have the opportunity to make the best of every day.
• We will treat your baby as a person, not as a disease. What is important to the baby and family is important to the care team.
• We will respond to the physical, psychological, social, and spiritual needs of your baby and family members.
• We will support you before, during, and after your baby’s death.

Using the mission, vision, core principles, and philosophy of palliative care as a backdrop, the neonatal and pediatric nursing community felt that the final step in formalizing a structure of care would be to construct precepts for the care. The Association of Pediatric Oncology Nurses (APON), National Association of Neonatal Nurses (NANN), and the Society of Pediatric Nurses (SPN) worked together to adapt the Precepts of Palliative Care, developed by the Last Acts Palliative Care Task Force, December, 1997. These precepts were originally written for the adult population and disseminated by the Last Acts Organization. The above organizations felt that newborns, infants, children, and their families represented a unique cohort of care where death was not expected or easily welcomed as a phase of the life cycle. The premise, however, is the same—that palliative care is comprehensive, holistic, and supportive, and it affirms life and regards dying as a profoundly personal process.5

So what does this mean for the neonatal nurse confronting a dying newborn or infant? It means that the nurse has to be present—to be fully attentive to the child and family, to separate his/her values regarding birth, life, and death from those of the family, and to clearly ask what it is that they need from their perspective. Of course, it means that the nurse must be ready to break the rules and turn over some control to the family, which is not something that most nurses feel comfortable doing. Nurses must adapt and individualize the care so that there is as much support for the positive development as possible for the infant and family. An IFCDC approach provides the context in which to render palliative and EOL care. This approach reminds the nurse that the families are parents first, and that they want to support their infant’s development and preserve their role as parents. It is only after that role is solidified that parents can become the caregiver to a child that may or will die. For culturally competent care to reflect the complexity of care that is much broader than ethnicity, the nurse must be sensitive to cultural, ethnic, and religious values.

Cultural Influences on Care

Cultural values and beliefs, both religious and ethnic, influence the family’s view of pain, suffering, and end of life (Table 53–2). The neonatal nurse must incorporate these values and beliefs into the plan of care if it is to be effective. Wong and colleagues6 and the Texas Children’s Cancer Center-Texas

<tr>
<td>under this general heading. Pentecostal is not a denomination, but a theological distinctive (pneumatology).</td>
<td>sinners after the age of accountability, which is not clearly defined.</td>
<td>appropriate, so is singing and scripture reading.</td>
<td>be explained. For example, a Pentecostal may have a problem with donating a heart to a “non-believer.”</td>
<td>see sickness as the will of God, thus one must “stand firm” in faith and accept the unseen reality, which many times may mean healing. As difficult as this position may seem, it must be noted that, when death occurs, Pentecostals may leap from miracle expectations to joyful hope and theology of heaven and resurrection without facing issues of anger or frustration due to unfulfilled expectations. Prayer, scriptures, singing, and anointing of the sick (not a sacrament) are appropriate/expected pastoral interventions.</td>
</tr>
<tr>
<td>Presbyterian</td>
<td>Baptism is a sacrament of the church but is not considered necessary for salvation. However, it is seen as an event to take place when possible, in the context of a worshipping community.</td>
<td>Family may desire visitation from clergy. Prayers for the dying, commendation of the dying, and prayers for the bereaved may be offered.</td>
<td>There is no formal statement regarding this issue.</td>
<td>Communion is a sacrament of the Church. It is generally celebrated with a patient in the presence of an ordained minister and elder. Presbyterians are free to make their own choices regarding the use of mechanical life-support measures. The Sacrament of Holy Communion sustains Catholics in sickness as in health. When the patient’s condition deteriorates, the sacrament is given as viaticum (“food for the journey”). Like Holy Communion, viaticum may be administered by a priest, deacon, or a sacramental minister. The church makes provisions for prayers for commendation of the dying that may be said by any of those listed above or by a layperson.</td>
</tr>
<tr>
<td>Roman Catholic</td>
<td>Infant baptism is practiced. In medical facilities, baptism is usually performed by a priest or deacon, as ordinary members of the sacrament. However, under extraordinary circumstances, baptism may be administered by a layperson, provided that the intention is to do as the church does, using the formula, “I baptise you in the name of the Father, the Son, and the Holy Spirit.”</td>
<td>Sacrament of the sick is the sacrament of healing and forgiveness. It is to be administered by a priest as early in the illness as possible. It is not a last rite to be administered at the point of death. The Roman Catholic Church makes provisions for prayers of commendation of the dying, which may be said by any priest, deacon sacramental minister, or layperson.</td>
<td>Catholics may donate or receive organ transplants.</td>
<td></td>

*Source: Adapted from Texas Children’s Cancer Center—Texas Children’s Hospital (2000), reference 7 (pp. 78–79).*
Children’s Hospital address cultural influence on care by outlining key aspects of health beliefs and practices that must be considered when providing any type of care. (For further information, see References 6 and 7.)

For example, when working with a Native American family, the nurse must consider that they may want to combine healing ceremonies from their tribal rituals with western medicine to alleviate suffering. In this instance, ethnic and religious beliefs are intertwined. But in other instances, religious versus ethnic values must be incorporated into care.

It must be remembered that not every family that identifies themselves as Methodist, for example, strictly adheres to all principles of that faith. The nurse must determine what role religion plays with each family. Additionally, we need to realize that for some cultures there is a biological birth and a social one. Social birth may not occur until it is clear that the infant will survive or until the infant has been given a name. How the family responds to the impending or possible death of the child will differ if the child is not considered a person until after a social birth.8

One example of religious belief affecting neonatal palliative care is that of an American Caucasian family strongly tied to the Catholic church. As their infant girl took a turn for the worst, the family was called. They immediately asked that she be baptized. The priest on call was unavailable and the family’s priest was 2 hours away. Rather than take the chance that no priest would come before the infant’s death, the nurse, a non-Catholic, baptized the baby. When the family arrived, they were reassured that yes, indeed, Angela had been baptized. The infant died peacefully in her parents’ arms long before either priest arrived. The family expressed comfort in knowing she was held within the religious arms of the church’s beliefs.

**Rights of Newborns and Their Families**

In today’s complex health care delivery system, many families feel they have no rights. The American Hospital Association (AHA) took this to heart and in 1973 developed A Patient’s Bill of Rights.9 Keeping this tradition in the adult community, neonatal nurses have long recognized that even the most premature infant has rights, as does the family (Table 53–3). The rights presented here need to be considered whenever neonatal palliative care is being rendered.

Why is it so important to adapt rights to neonates and their families? Because most neonatal health professionals recognize the unique needs of this population—their rights and their care needs. An infant has no history—as one family said, the infant does not know what the future possibilities are; there is no frame of reference. For the family, there are no memories of a past except prenatally, so palliative care is building a lifetime of memories. There are other aspects that are different as well. Table 53–4 summarizes these differences.

**Table 53–3**

**Palliative Care Plan**

Catlin and Carter10 developed a palliative care protocol that has been disseminated widely since 2002 (see Appendix 53–1). Based on their research in neonatal palliative care, it is one of the only evidence-based plans available. It incorporates all of the elements previously discussed in this chapter. This protocol exemplifies the care that was provided in the chapter’s opening exemplar—Christian’s story. Their respect for the family wishes and alleviation of the pain and suffering were addressed. A team-integrated approach to care was used.

Sometimes we underestimate what toll palliative and EOL care can take on us as caregivers. We often feel torn between spending quality time with a dying child and family and caring for our other patients. We are only human. We need to give ourselves permission to set priorities and to make the most of the time we do have with child and family. Sometimes a word, a gentle touch, a look across the room while providing care for another baby is enough for a parent to know we are there for them. While it is not ideal to be multitasking while caring for a dying child, it is the reality of today’s work environment. We also have to realize that sometimes we need to ask for help, to give someone else the opportunity to provide support when we cannot. Try to remember that for some parents this the first time they have lost a family member, let alone a child. They don’t know what to expect or if that “ad” in the newspaper with funeral arrangements costs anything. We have to anticipate these questions, but we also have to realize that some days we deal better with these situations.
than others. For example, if you have just had a baby yourself, it may be very difficult to care for a newborn who is dying. That is okay. But make sure that someone knows this and, if possible, get reassigned. Communication is the key for others to know what you need—whether it is a new assignment, to have more time with the child and family, or to attend the funeral. You need to make it clear what you need. We practice asking families “Tell me what you need” but often neglect ourselves.

### Table 53–4

<td>Patient is often in a highly technical medical environment.</td>
<td>Family fears that care at home is not as good as care at the hospital.</td>
</tr>
</tbody>
</table>

### Caregiver Issues

- Caregivers need to protect children, parents, and siblings.
- Caregivers feel a sense of failure in not saving the child.
- Caregivers feel a sense of “ownership” of children, even at the expense of parents.
- Caregivers have out-of-date ideas about pain in children, especially infants.
- Caregivers lack knowledge about children’s disease processes.
- Influence of “unfinished business” on style of care.

### Institutional/Agency issues

- There is less reimbursement or none for children’s hospice/home care.
- High staff-intensity caring is required for children at home.
- Ongoing staff support is necessary.
- Children’s services have immediate appeal to public.
- Special competencies are needed in pediatric care.
- Assess how admission criteria may screen out children.
- Address unusual bereavement needs of family members.

Adapted from Kuebler & Berry (2002), reference 37 (used with permission); and Children’s Hospice International, reference 18 (prepared by Paul R. Brenner).

### Summary

Neonates who would benefit from excellent palliative care could die minutes, months, or years after birth with a life-threatening anomaly or illness. Because the prognosis is so difficult to predict, the professional is called upon to focus on providing care that is often changing and challenges existing health care system structures. The period of life may be so unpredictable that the focus needs to be on excellent symptom management, while promoting development of the child and family within their community. Families and professionals have the difficult task of helping the child live as fully as possible while preparing for and accepting that the child may not live a long time. This requires a committed interdisciplinary team with community linkages as appropriate.

Regardless of the length of life or the place where that life is lived, excellent palliative care includes optimum symptom relief for the neonate, honoring the parents’ wishes, providing ongoing support to parents and family, planning for the death, and honoring the life by creating memories of the life. Even though the neonate cannot be cured, let it never be said that “there is nothing we can do.”

**APPENDIX 53–1**

### Neonatal End-of-Life Palliative Care Protocol*

The purpose of this protocol of care is to educate professionals and enhance their preparation and support for a peaceful, pain-free, and family-centered death for dying newborns.

### Planning for a Palliative Care Environment

To begin a palliative care program, one must realize that some institutions find it difficult to confront the issue of a dying child. So to begin to create a palliative care environment, there must be staff education and buy-in. This education must address cultural issues that affect caregiving. Ethical issues must be addressed either by the group creating the environment or by consultants who specialize in ethics.

For the family, staff must treat the family as care partners and not visitors. They must recognize that someone needs to be available 24/7 to address issues such as advance directives and symptom and pain management both in the hospital and at home if discharge is possible. There must be a mechanism to prepare the community for the child’s entrance home or to hospice. This preparation includes what is appropriate to say to friends, relatives, and visitors.

### Prenatal Discussion of Palliative Care

It is essential that fetal development and viability be discussed with all families as a part of prenatal care packages and classes.

---

and to all families receiving assisted reproductive therapies. As the course of prenatal care progresses, pregnant women should be made aware that newborns in the very early gestational periods of 22 to 24 weeks and birth weights of less than 500 grams may not be responsive to resuscitation or applied neonatal intensive care.

**Physician Considerations**

The families need honest, straightforward language. They need to know their options and it is essential that they understand what to expect. Usually the physician delivers this information, but the nurse is generally the one that can help the parents sort through feelings and grasp what they were just told. If this incident is sudden, such as an unexpected premature birth, then the family’s ability to comprehend and retain what is being said is limited. Reinforcement at a later time is advisable.

**Family Considerations**

Peer support from families that have experienced a similar infant illness or death may help the family cope. If the family finds out that the pregnancy is not viable, then it is up the health care team to help support their needs and to garner resources such as other family members, spiritual counselors, and friends. Helping the family to experience the normal parenting tasks such as naming the baby is very appropriate and helpful. This act helps the family gain some control and to be a parent first and build memories of that experience.

**Transport Issues**

It is best that mothers not be separated from their newborn infants. Transport is considered both traumatic and expensive, and if the newborn’s condition is incompatible with prolonged life, then arrangements to stay in the local hospital may generally be preferred. It is best to avoid transferring dying newborns to Level III NICUs if nothing more can be done there than at the local hospital. The local area is recognized as that location at which parents have their support system, rapport with their established health care providers, a spiritual/religious community, and funeral availability.

The key to whatever decision is made, referral or not, requires good, clear communication with the family and between the two institutions. The family should not feel they are being sent away or given the wrong message by the nature of the transfer, or even return from a tertiary center once a referral is made if there is nothing to be done. The family needs a consistent message if trust is to be developed.

**Which Newborns Should Receive Palliative Care?**

While many aspects of palliative care should be integrated into the care of all newborns, there are infants born for whom parents and the health care professionals believe that palliative care is the most appropriate form of care. The following list includes categories of newborns that have experienced the transition from life-extending technological support to palliative care. The individual context of applying palliative care will require that each case, in each family, within each health care center, be explored individually. These categories of newborns are provided for educational purposes and may engender discussion at the local institutional level.

- Newborns at the threshold of viability
- Newborns with complex or multiple congenital anomalies incompatible with prolonged life, where neonatal intensive care will not affect long-term outcome
- Newborns not responding to intensive care intervention, who are deteriorating despite all appropriate efforts, or in combination with a life-threatening acute event

**Introducing the Palliative Care Model to Parents**

Speaking to parents about palliative care is difficult. There is heartache from the staff and heartfelt sympathy for the parents. The following points are offered to help physicians and nurse practitioners facilitate the process:

- Let the family know they will not be abandoned.
- Assist the family in obtaining all of the medical information that they want. Tell them that the entire medical team wishes the situation were different. Let them know you will support them every step of the way and that their infant is a valued and loved member of their family.
- Hold conversations in a quiet, private, and physically comfortable space.
- Give them your beeper number or telephone number to call you after they have digested the information and have more questions. Offer the ability to have a second opinion and/or an ethics consultation.
- Provide parents time to consult the local regional center that works with children with special needs or their area pediatrician, who can provide information on projected abilities and disabilities.
- Offer to introduce them to parents who have been in a similar situation.
- When possible, use lay-person language to clarify medical terms, and allow a great deal of time for parents to process the information.
- The terms “withdrawal of treatment,” such as referring to the stopping of life support, or “withdrawal of care,” referring to the stopping of feedings or other supportive interventions, should be avoided. The exact treatment or care that is to be terminated should be specifically explained so that the intention is clear.
- Use terms such as “change in care” or “change in treatment.”
• Communicate and collaborate with parents at all times. Efforts should be made to clarify mutually derived goals of care for the infant. Give as many choices as possible about how palliative care should be implemented for their infant. Inform the parents of improved access to the infant for holding, cuddling, kangaroo care, and breast-feeding. Use of developmental care approaches such as these promotes the building of a relationship between the infant and parents.

• If the transition in care involves the removal of ventilatory support, explain that the use of ventilators is for the improvement of heart/lung conditions until cure, when cure is a likely outcome.

• Tell the parents that you cannot change the situation but you can support the infant’s short life with comfort and dignity. Explain that discontinuing interventions that cause suffering is a brave and loving action to take for their infant.

• Validate the loss of the dreamed-for healthy infant, but point out the good/memorable features he/she has. Help parents look past any deformities and work to alleviate any blame they may express.

• Encourage parents to be a family as much as possible. Refer to the newborn by name. Assist them to plan what they would like to do while the infant is still alive.

• Encourage them to ask support persons to join them on the unit. Facilitate sibling visitation. Support siblings with child-life specialists on staff.

• In daily conversation, avoid terms that express improvement such as “good,” “stable,” “better” in reference to the dying patient so as not to confuse parents.

• Prepare the family for what may happen as the infant dies.

• Introduce families to the chaplain and social worker early in the process.

• Parents who are educated in what to expect and who are encouraged to participate in, or even orchestrate, the dying process and environment of their infant in a manner they find meaningful

• Flexibility of the facility and staff in responding to parental wishes, such as participation of siblings and other family members, and including wishes of parents and families who do not wish to be present

• Institutional policies that allow staff flexibility to respond to parental wishes

• Providing time to create memories, such as allowing parents to dress, diaper, and bathe their infant, feed him/her (if it is possible), take photos, and hold the infant in their arms. If they wish to take the infant outdoors to a peaceful and natural setting, that should be encouraged.

• Siblings should be made comfortable; they may wish to write letters or draw for the infant. Snacks should be available.

• Allowing the family to stay with the infant as long as they need to, including after death occurs

• The process for treating the dying infant11–13 is well described in the literature and by the various bereavement programs.

• Parents should be assisted in making plans for a memorial service, burial, etc. Some parents might wish to carry or accompany the infant’s body to the morgue, or take it to the funeral home themselves. Issues such as autopsy, cremation, burial, and who may transport the body should be discussed, especially if the parents are far from home and wish to take the body back to their home area for burial. In some states, hospitals may release a body to parents after notifying the county department of vital statistics. The family must sign a form for removal of the body. The quality assurance department should be notified. Further discussion of autopsy and organ/tissue donation issues is included.

Specific skills are needed by the staff to provide palliative care. These include:

• A physician leader of the team who is familiar with family-centered care and the tenets of palliative/hospice care

• A trained nursing staff, clinical social workers, and clergy supportive of this manner of care

• Agreement to cease all invasive care, including taking frequent vital signs, monitoring, medical machinery, and artificial feeding

• Removal of all medications other than those to provide comfort or to prevent or treat a troubling symptom, with continued IV access for pain medication and anxiolytics

• Maintenance of skin care, participation in discussion on the appropriateness of feeding, and prevention of air hunger

Optimal Environment for Neonatal Death

When the decision is made that a newborn infant may be close to death, there are several components to optimizing the care. These include:

• Compassionate, nonjudgmental, consistent staff for each infant, including physicians knowledgeable in palliative care. If consistent staff is not an option in a particular unit, then agreement on the plan of care is essential, with proposed revisions to care discussed with the whole team.

• Nurses and other health care staff educated in providing a meaningful experience for the family while caring for the family’s psychosocial needs, including a period of time after the death
• Use of simple blow-by oxygen or suctioning if needed for comfort
• Continuous observation and gentle assessment by nursing staff as individualized by parent wishes
• Physicians’ notes describing the need for ongoing physician observation and nursing staff interventions to provide the needed level of care
• Appropriate palliative care orders on the chart

Location for Provision of Palliative Care

Location is not as important as the “mindset” of persons involved in EOL care. The attitude of staff, their desire to care for dying newborns and their families, their training in observation, support, and symptom management, and their knowledge of how to apply a bereavement protocol are more important than the physical location of the patient. Many agree that an active NICU may not be the optimal place for a dying newborn. Whether the infant is moved to a room off of the unit (e.g., a family room), onto a general pediatrics ward, or kept on the postpartum floor, the best available physical space with privacy and comfort should be chosen.

The families need help to make the decision of how and where the infant is to be given care. If families take the infant home, coordination with the EMS personnel may be necessary to prevent undesired intervention. Parents need to be instructed not to call 911 because in some places emergency medical technicians (EMTs) are obligated to provide cardiopulmonary resuscitation (CPR). A letter describing the diagnosis, existence of in-hospital do-not-resuscitate (DNR) order, and hospice care plan for home with the full expectation that the patient will die should be provided to the parents, their primary physician, home-health agency/hospice, and perhaps the county EMS coordinator. Generally, hospice nurses are allowed to confirm a patient’s death.

Ventilator Removal, Pain and Symptom Management

At times, cessation of certain technological supports accompanies the provision of palliative care. The following information addresses (1) how to prepare the family, staff, and facility for discontinuation of ventilator support, and (2) the process of removing the ventilator in a manner that minimizes discomfort for the infant and the family. The latter includes who will be present at the time of extubation. A plan must be worked out with the family about what medications and support will be given to alleviate pain and suffering and what they can expect the dying process to be like for their baby. Consideration of developmentally supportive care that is attuned to ambient light and noise as well as comfort measures are important. These should incorporate cultural considerations.

Mementos can be obtained by nurses, such as a lock of hair, hand or footprints in plaster, and photos and/or videotapes of the family together if this is culturally appropriate. If the infant has serious anomalies, photos of hands, ears, lips, feet, can be provided. Ear prints and lip prints are possible. Some parents have indicated that mementos of a newborn who died are not acceptable in their culture.

When Death Does Not Occur After Cessation of Aggressive Support

A private room somewhere in the hospital is recommended where nurses trained in palliative care are available. If the expected time for expiration passes and death does not take place, the infant could be discharged to home for ongoing palliative care services. The parents, NICU staff, and the hospice staff should meet to make plans for home care, including the investigation of what services are offered and what insurance will cover. Continued palliative care/hospice services with home nursing care is essential, including the possibility of ventilator removal at home.

If the infant is to go home, a procedure for dispensing outpatient medications should be in place. All needed drugs and directions for use should be sent along with infant so that parents do not have to go to a pharmacy to fill prescriptions. Identifying and communicating with a community health care provider who will continue with the infant’s home care needs is essential.

Some families and health care providers feel dying newborns should be fed, and if unable to suck, should be tube fed. Others feel that artificial feeding is inappropriate. However, withholding of feedings is an ethical dilemma for many health professionals and families and needs careful consideration. Recent research indicates that feeding can be burdensome and that an overload of fluids can impede respirations. In all cases, infants should receive care to keep their mouth and lips moist. Drops of sucrose water have been found to be a comfort agent if the infant can swallow, and they may be absorbed through the buccal membrane.

Parents who feel they cannot take the infant home should be assisted to find hospice care placement.

Discussion of Organ and Tissue Procurement and Autopsy

At some point in the course of care, organ and tissue donation and autopsy will need to be discussed. Prior to discussion with families, the regional organ donation center should be contacted to see if a particular infant qualifies as a potential donor. In some areas, only corneas or heart valves are valuable in an infant under 10 pounds, but in different locations, other organs (e.g., heart) or tissues may be appropriate. It is important to know if a newborn has no potential donor use and to communicate this respectfully. Parents often desire the ability to give this gift and may be doubly hurt if they are hoping for the opportunity to help others and are turned down.

The person who discusses organ/tissue procurement must be specially trained. While the physician usually initiates this, a nurse, chaplain, or representative from donor services may conduct the conversation with tact and compassion. The provider should be aware of cultural, traditional, or religious
values that would preclude organ donation for a specific family, as many cultures and religions would consider this desecration of the dead infant.

Suggestions Concerning Autopsy

Requests for autopsies are not required in all states, but may be considered appropriate in many instances of infant death. If the medical examiner or coroner is involved in the case, laws may require autopsy. Some providers feel that asking for an autopsy is important in order to potentially provide parents with some answers regarding their infant’s illness and death. The placenta may also be used for testing to provide information. In the discussion, parents may wish to know all or some of the following:

- Autopsy does not cause any pain or suffering to the infant; it is done only after death.
- The body is handled with the ultimate respect.
- Some insurance companies pay for a physician-ordered autopsy.
- Final results are returned in approximately 6 to 8 weeks, at which time the primary physician can meet with the parents, conduct a telephone conference, or communicate by letter to discuss the results.

Family Care: Cultural, Spiritual, and Practical

Family Needs

The hospital social worker is an essential component of supportive palliative care. Families may immediately need financial assistance, access to transportation, and a place to stay.

Practical Considerations. Parents of multiples in which some lived and one died will need special attention to validate their bereavement as well as to support their love for their living child(ren).

Time should be permitted for the parents to contact the needed authority in their culture and to plan any necessary ceremony, some of which may require special permission, for example use of incense.

Cultural Sensitivity. These support needs should be anticipated and provided as much as possible.

- When using a translator, simple words and phrases should be used so that the translator can convey the message exactly as it is given. It is most appropriate to use hospital-trained and certified translators to ensure accuracy.
- Whenever possible, written materials should be given in the family’s primary language, in an easy-to-read format, culturally and linguistically appropriate for the family.
- Culturally sensitive grief counseling and contact with a support group of other parents who have been through this is helpful.

Family Follow-Up Care

Families who have experienced a neonatal death will likely leave the facility in a shocked state. Families can be best be served by:

- Establishing contact with a social worker, chaplain, or grief counselor prior to discharge
- Receiving an information packet as described and a date for a follow-up discussion with the attending physician (which may be in conjunction with autopsy results)
- Notifying the family’s obstetrician of the death no matter how long after delivery it occurred
- A home visit by one of the staff or a public health nurse within a few days
- Phone calls weekly, then monthly, then at 6-month intervals if parents agree. Also providing contact on significant days such as Mother’s Day, the infant’s due date, or anniversary of death
- Invite family to a group memorial service held by the hospital for those who have lost pregnancies or infants in the past year.
- Keep in mind that subsequent pregnancy may be difficult and offer support at that time; include genetic counseling if indicated.
- Keep snapshots and mementos on the unit if parents do not wish to take them at the time, as some parents may reconsider later.

Ongoing Staff Support

The work of providing EOL care for newborns and their families is very intense. Staff needing support must not be limited to the nursing staff, and must include physicians and all health care and ancillary personnel who have interacted with the infant or family. Suggested support includes:

- Facilitated meetings of the multidisciplinary team during the process are needed, especially if some of the team members are reluctant to change to this mode of care.
- Debriefings after every infant’s death and after any critical incident will be helpful for the staff.
- Meetings or counseling sessions should be part of regular work hours and not held on voluntary or unpaid time.
- Moral support for the nurses and physicians directly caring for the dying newborn is required from peers as well as the unit director, other neonatologists, chaplain, and nursing house supervisor.
- Nursing staff scheduling should be flexible and allow for overtime to continue with the family or to orient another nurse to take over.
- If they wish, the primary nurse and physician should be called if not present at the actual time of the infant’s dying. With permission by the parents,
they should be allowed to attend the funeral if desired and to take time off afterwards if needed.

APPENDIX ACKNOWLEDGMENTS

Catlin and Carter wish to include the following acknowledgments for assistance in the development of this neonatal end-of-life palliative care protocol: We thank our reviewers Alex G. M. Campbell, MD, David Clark MD, Joel Frader, MD, John Lantos, MD and Bill Silverman, MD, and our Delphi methodology consultant, Dr. Carol Lindemann. The project was funded by the American Nurses Foundation Julia Hardy RN Scholar Award, with travel support from the Lambda Gamma Chapter of Sigma Theta Tau. We appreciate support from our institutions, Napa Valley College and Vanderbilt University College of Medicine, and from the IRB at Queen of the Valley Medical Center in Napa, California.

We sincerely thank our 101 participants for their time, wisdom, and commitment. Readers may contact us for participant names as space did not permit listing: acatlin@napanet.net; bcarter@ghsystem.com

Grief and Bereavement in Pediatric Palliative Care

It’s been a challenge for all of us since Sammy died. It’s so hard to understand why a child has to die . . . it just doesn’t seem right. I still cry a lot, and some days are harder than others. I get a lot of support from my mother and sisters, but my husband doesn’t have that kind of support from his family. And he doesn’t like to talk much about what happened. I think he works things out on the rugby field. My older daughter (age 8) seems to be doing okay now, but for a while, she wasn’t concentrating in school at all, and just didn’t seem like herself. The little ones (4-year old twins) . . . well, they ask the hardest questions, like “Will Sammy be here for Christmas?” They are just trying to figure out something that none of us can really figure out.—Mother, age 35, whose 7-year-old died of cancer 18 months ago

- **Key Points**
- Bereavement care for all family members is an integral component of pediatric palliative care.
- Grieving after a death is a normal process; however, some grief reactions become complicated, and nurses must assess for factors that put family members at risk for such reactions.
- Grief assessment begins at the time of diagnosis of a child’s life-limiting condition, applies to all family members, and continues into the bereavement period following the child’s death.
- Nurses have a responsibility to create supportive environments in which family members feel free to express their grief.
- Caring for dying children requires nurses to attend to their own personal and professional responses to death, dying, and bereavement as a basis for providing optimal care to families.

Effective and compassionate care for children with life-threatening conditions and their families is an integral and important part of care from diagnosis through death and bereavement. This guiding principle, one of seven put forth by the Institute of Medicine report on the status of palliative and end-of-life care for children and their families, emphasizes that care continues for the family following the child’s death. Though medical science has contributed significantly to the treatment of children with life-limiting illnesses or conditions, children still die from cancer, cardiac disease, respiratory conditions, genetic conditions, and more. Moreover, thousands of neonates die each year and thousands more children of all ages, particularly toddlers and adolescents, die as a result of trauma. Approximately 55,000 children die annually in the United States. Regardless of the cause of death, the death of a child is a tragedy, an incomparable life event that has an impact on all family members, friends of the family, and the community in which the family lives. A child’s death also affects the physicians, nurses, social workers, and other health care personnel who provide care for the dying child. The purpose of this chapter is to define common words associated with grief; to describe factors that affect the grief of family members, the effects of grief upon them, and the nurse’s role in helping grieving individuals and their families; and to discuss the needs of nurses who work in pediatric palliative care.

**Grief as a Process**

Death is a part of each individual life, something we all must face though we resist even the thought of our own mortality. The hoped-for pattern is that we experience deaths of others that are easier in earlier life, for us to build the skills to aid us with the more difficult deaths in later life. The death of one’s
child, though, sits outside of that hoped-for pattern. The grief associated with a child's death begins even before the actual death event, as the child’s parents and other family members anticipate the death and experience the child’s dying, and their grief continues long past the child’s death. Many parents feel they never “recover” from the death of their child. They may resume daily activities, adjust to life without their child’s presence, and find new pleasures in life, but most parents feel they remain vulnerable and feel they are not the same people they were before the child’s death.3 The death of a child, or any beloved person, is not something one “gets over”; rather, over time, one learns to integrate the loss into one’s life. Indeed, grief is a process that is not always orderly and predictable, and given that grief is the individual experience of each human being, it manifests in many diverse ways.

Grief, Bereavement, and Mourning

The term grief is often used to refer to the emotional response to a loss.5 But grief is much more than emotion—it is an overwhelming and acute sense of loss and despair; it is the personalized feeling and response that an individual makes to real, perceived, or anticipated death; it encompasses feelings, physical sensations, cognitions, and behaviors. Grief encompasses every domain of human life—physical, emotional, psychological, social, and spiritual. Sadness, anger, numbness, sleep and eating disturbances, inability to concentrate, fatigue, existential angst, and tension in interpersonal interactions are among the responses to a loved one's death.

Grief occurs when a loss is deemed as personally significant to the individual. For example, hearing the news about a child's death in a bicycle accident may produce sadness, but not necessarily a grief reaction. However, grief will ensue when it is learned that the child is your nephew. To a certain degree, who or what we consider to be personally significant is culturally defined. For example, in the contemporary United States, the death of one's child is expected to result in profound grief. In fact, a classic research study suggests that grief in response to a child's death is more intense than grief following the death of a spouse or parent.4

The term bereavement refers to the state of being bereaved or deprived of something. The word derives from an Old English word, “reave,” which means to plunder, spoil, or rob.5 This meaning implies that the loss object is a valued one, together with a suggestion of violence in the way in which the loss occurred. This definition is especially apt for bereaved parents, who often report feeling as if a part of them has been torn away. As the bereaved mother of a 22-month old who died following a brain aneurysm sighed:

When my son died, it was as if my heart had been stolen from my breast, and my arms that held him ripped from their sockets.

Mourning refers to the outward, social expression of grief, often through ritual and sometimes to the psychological process of adapting to loss.6 How one expresses a loss may be dictated by cultural norms, customs, and practices, including rituals and traditions. Some cultures may be very emotional and verbal in their expression of loss, others may appear stoic and businesslike. Religious and cultural beliefs may also dictate how long one mourns and how one behaves during the bereavement period. In addition, outward expression of loss may be influenced by the individual’s personality and life experiences.7

Types of Grief

It is important for nurses’ understanding of grief and bereavement and for the implementation of appropriate interventions to be aware of several types, or variations, of grief that have been described in the thanatology literature, including anticipatory grief, disenfranchised grief, and pathological grief reactions or complicated grief. How these concepts apply to pediatric palliative care is particularly important.

Anticipatory Grief

Anticipatory grief often occurs in advance of an expected loss. Rando6 indicates that anticipatory grief entails grieving not just for future losses, but also for losses that have already occurred and for current losses. It may be associated with the losses of expectations for a “normal” life that are associated with a particular diagnosis, with acute and chronic illness, or with death. For example, parents may fear the potential loss of health in their child when a child is being tested for unusual symptoms. All family members may grieve the expected loss of a part of the child’s body, mental function, or self-image; they may grieve the loss of the child’s and their own independence, choice, and dreams. Anticipatory grief occurs while the ill child is still alive, and this allows for hope. This is a subtle difference that makes anticipatory grief unique, and helps account for what parents often describe as an “emotional roller coaster,” particularly for parents of children with long-term chronic illness. Their experience of witnessing the child’s physical deterioration and worsening of symptoms, interspersed with remissions, “good” days, and seeming progress toward health lays fertile ground for emotional ups and downs and hope for the child’s recovery. Over time, however, the focus of hope changes, and nurses can play a critical role in facilitating the expression of that hope. Initially, parents of children with cancer, for example, focus their hope on the possibility of cure. Each exacerbation chips away at the hope for the child’s full recovery, and family members hope for longer remissions. Eventually, they hope their child will be able to live until he reaches a particular milestone, such as graduation, a special birthday, or the next holiday. As the child’s condition worsens, parents may hope that their wish to care for their child at home
will be possible, and that their child will not suffer at the end. Hope is life-sustaining; health care providers should support family members in their hope, refraining from crushing hope with overdoses of facts. In response to a mother’s proclamation that her child will overcome a serious illness, the nurse can empathize, “I certainly do hope so.” The death is anticipated, but it has not occurred, and in the parents’ eyes, there is a chance, no matter how small, that it might not occur:

My son has been to the PICU three times. At his first transfer to the PICU, my sorrow was beyond description. At that time, I thought I would never see him again. But my son has fought against his cancer every time. Whenever he came back to the ward from the PICU... I remember recently that day was 3 days before his 13th birthday... it was so amazing and I prayed thanks to God for allowing me to hope for his life again.

For more information on hope, the reader is referred to Chapter 26.

Though painful, anticipatory grieving does present an opportunity for families to begin to think about their future without the child. It can help family members begin to face the existential questions that arise when a child is dying. It can help families begin to the process of reorganizing their fractured lives. Anticipatory grieving can also take its toll, especially when the child’s illness endures. Rando9 interviewed parents whose child had died from cancer, and suggests there is an optimal length of anticipatory grief of 6 to 18 months. A shorter time did not give parents enough time to prepare for the loss, and a longer period had a debilitating effect on them.

Unacknowledged grief before the death may inhibit communication and preparation for death which, in turn, may contribute to strong feelings of subsequent guilt and regret.1 However, anticipatory grief does not mean the grieving that occurs after the child’s death is somehow easier or less painful for parents and other family members. Health care providers cannot assume that family members whose child died following a long-term illness grieve “less” than those whose child dies suddenly and unexpectedly. In fact, every child’s death is unexpected. Even when parents know their child will die, the actual moment of death is often unexpected, as reflected in parents’ words: “I knew the end was near, but I really thought he would make it until his brother got home from college.” Or, as the 7-year old sister wept following her brother’s death a few days before her birthday: “But, he was coming to my party.”

Disenfranchised Grief

Disenfranchised grief acknowledges the social context of grief. It refers to the grief that persons experience when they incur a loss that is not or cannot be openly acknowledged, publicly mourned, or socially supported.3,11 Those at risk include, for example, classmates, team mates, teachers, coaches, school bus drivers, crossing guards, or past boyfriends/girlfriends of the child or adolescent who died—those whose relationship with the now-deceased child/adolescent is not regarded as significant. Also feeling disenfranchised are those grieving a terminated pregnancy or a neonatal death where the significance of these losses may not even be acknowledged, or if it is, comments such as “You can try again” reflect insensitive misunderstanding of the parents’ grief. Families of children with serious cognitive or physical limitations, from progressive neurodegenerative illnesses, for example, may experience disenfranchised grief when others perceive the child’s death as a “blessing” rather than a loss for the family. Disenfranchised grief also occurs when bereaved persons are not recognized by society as capable of grief or needing to mourn. Young children, mentally challenged children or adults, and abusing parents whose actions have caused the child’s death are often disenfranchised in this way.

Complicated or Troubled Grief

The processes of grief and mourning are normal and healthy aspects of human living. However, all human processes can go awry, especially in particularly difficult situations, and such grief is sometimes referred to as “complicated” grieving. However, as everyone who has experienced the loss of a loved one knows, all grief is complicated. It’s just that, sometimes, grief is more complicated than at other times. But common terminology differentiates complicated from uncomplicated grief, with the latter referring to the typical feelings, behaviors, and reactions to loss; complicated grief refers to a response to loss that is more intense and longer in duration than usual.12 Worden13 has outlined four basic types of complicated grief: (1) chronic grief is characterized by grief reactions that do not subside and continue over long periods of time; (2) delayed grief is characterized by grief reactions that are suppressed or postponed, and the family member consciously or unconsciously avoids the pain of the loss; (3) exaggerated grief occurs when the family member resorts to self-destructive behaviors such as suicide; and (4) masked grief occurs when the family member is not aware that behaviors that interfere with normal functioning are a result of the loss.

Those who are mourning the loss of a child are at risk for complicated grief. Other risk factors include: preexisting difficulties in the relationship with the deceased (such as between a parent and a delinquent daughter); the circumstances of the death (such as traumatic death through suicide or homicide); chronic illness; the survivor’s own history of depressive illness; multiple losses or history of troubled grief reactions to previous deaths; difficulty with the dying process; when the death is socially negated; or a lack of social support system or faith system.

Factors Affecting the Grief Process

Family responses to grief vary widely and depend on a multitude of factors. Some of these factors may be obvious, some less apparent, but all influence how individual family members cope
with the pain of a child’s death. Influencing factors fall into three broad categories. Individual variables have to do with attributes of the bereaved, including the relationship between the child who died and other family members; environmental factors have to do with the social, familial, and cultural environments; and situational factors pertain to the characteristics of the death. All factors interact with one another to provide the context of grief.

**Individual Factors**

Individual, or personal, characteristics that affect the grief process may include history and relationship with the child, previous exposure to death, dying, grief and loss, developmental level, and temperament and coping styles.

**History and Relationship with the Child.** Each parent, sibling, or grandparent has a unique history and relationship with the deceased child. Histories among siblings are closely intertwined because siblings often develop special bonds that are unlike any other. The closer two siblings are to one another before death, the more behavior problems the surviving sibling may have following the death. Similarly, grandparents and children barely know one another. Some histories among the children and other family members will have been predominantly troubled, filled with tension and conflict and others filled with laughter and harmony.

**Previous Experience with Death.** Past experiences with death and the learned response to loss also affect how each family member will grieve a child’s death. Other deaths of a similar nature may have occurred in the family, such as when more than one child suffers from the same life-limiting genetic disorder. How previous losses were handled in the family will influence the current situation.

In the R. family, for example, when Grandfather R. was 10 years old, his older brother was killed in a car accident. No one explained to the grieving child what had happened, he was not allowed to attend the funeral, and following the death, regretted that he had not been the one to die because he felt his brother was so much smarter than he. As a young boy, he decided unconsciously that he would hide his pain behind a wall of silence; he seldom displayed or talked about emotions. When Mr. R’s grandson died from cancer at age 11 years, Mr. R was flooded with memories and sadness. His previously learned coping through silence and withdrawal resulted in his being unprepared for how to help his distraught son and himself with the current loss.

**Developmental Level.** When we think of “developmental level,” we often think only of children and adolescents. But development is a lifelong process; therefore, the developmental level of each grieving individual must be considered. Young parents who are facing the death of their child have not typically experienced many life crises; elderly grandparents may be struggling under the burden of having faced too many. A teenage mother, struggling to be independent from her parents, faces new challenges when she must rely on them for assistance because her baby becomes ill and dies. A midlife father, anxious about his family’s financial future following his son’s long-term illness, agonizes deeply over the expenses of his son’s funeral and feels guilty about his feelings. A grandmother who overcame breast cancer at age 65 laments over why her 20-year-old granddaughter was the one to die from cancer.

**Personality and Coping Style.** Individuals of all ages vary in temperament and personality, and styles of interacting with the world are evident in even the youngest children. Some youngsters are naturally more extroverted; they talk easily with others and eagerly seek out resources and sources of support and comfort. Others are more introverted; they keep their thoughts and feelings to themselves and may prefer the solitude of reading or quiet play. Doka describes styles of grieving among adults that occur along a continuum, with “instrumental” grieving at one end and “intuitive” grieving at the other. Most people fall in the middle, but describing the extremes of the continuum clarifies the differences and may be helpful in understanding how parents and other family members manifest their grief. Intuitive grievers fit the pattern of how we think individuals “should” grieve. They express strong affective reactions, their expression mirrors their inner feelings, and their adaptation involves expression and exploration of feelings. In contrast, the grief experience for instrumental grievers is primarily cognitive or physical, expressed cognitively or behaviorally, and adaptation generally involves thinking and doing. Gender, culture, temperament, and a variety of other factors influence grieving styles. Caution is advised against assuming that mothers are more intuitive in style and fathers more instrumental. Both parents must be assessed individually to determine where on the continuum their style rests. It is important, as well, to remember that these terms represent differences, not deficiencies, in grieving styles. Most parents in pediatric palliative care are young and likely inexperienced with illness, hospitals, technologies, dying, and death. Consequently, they typically have few skills for dealing with significant loss.

**Environmental Factors**

Environmental factors include the role of the deceased child in the family and various aspects of the family itself.

**Role in the Family of the Child Who Died.** Ordinal position often defines children’s roles in the family. When a child dies, shifts occur among the other children. For example, Jose was the eldest of three sons. When he died, his father told Marco, the middle son, that he was now the “oldest.” The three boys had shared very close relationships, and now they felt their father was “forgetting” Jose by no longer regarding him as the eldest.
Children also play particular social, spiritual, and physical roles in the family; the child’s absence leaves their role unfilled and resultant adjustments can be difficult for remaining family members. Jose had been the “leader”—Marco did not want to assume his brother’s leadership role. As well, how the child defined the other members of the family affects their grieving. Again, Jose particularly liked to joke about his “little” brother who was growing to be taller than Jose. Marco had enjoyed the teasing and did not want to displace his admired older brother. Tension grew between father and sons.

**Family Characteristics.** Even before their child dies, families have characteristic ways of being in the world, of solving problems, of managing crises, of interacting with one another, and of relating to those outside the family. When a child is seriously ill and dies, families respond in the ways that are typical for how they manage other life events. These ways of coping are more or less functional. Earlier research with families of adult patients and with pediatric patients documented eight dimensions of family functioning: communicating openly, dealing with feelings, defining roles, solving problems, using resources, incorporating changes, considering others, and confronting beliefs. These dimensions occur along a continuum of functionality so that family interactions tend to vary along the continuum rather than being positive or negative, or good or bad. In families where thoughts and opinions are expressed freely without fear of recrimination, where a wide range of feelings is expressed and differences tolerated, where roles are flexible, where problem solving instead of blaming is the pattern for dealing with challenges, where families are able to ask for and receive assistance from others, and where beliefs and values are confronted and examined, the children and all family members are better able to manage their grief and support one another. The nurse’s role is to assess each family’s way of functioning, and to realize that some families are more difficult to assess and work with than others. For example, some families may not wish to share information in the presence of their children, others do not wish to discuss matters with any relatives in the room, while other families include everyone in most discussions. Thus, it is important for the nurse to gather information over time, and to talk with more than one family member to appreciate the varied perspectives. When families are less functional, practitioners may want to offer potential resources one at a time, with considerable attention paid to the possible disruption that would result from each suggestion. In more functional families, a list of possible options can be presented and considered all at once. The vast majority of families value the opportunity to tell their story, and thus listening becomes a central aspect of caring for all grieving families.

**Social/cultural Characteristics.** No one grieves in isolation from others. Individual responses are shaped by distinct social and cultural circumstances, and, in turn, each grieving person plays many roles in shaping family and community responses. Friends, extended family, and community support also influence how the family unit and individual family members function and come to terms with a child’s death. A friend with a sensitive presence and listening ear can be of significant support to a grieving parent or sibling. Or, when grieving parents are challenged by the responsibilities of parenthood, a kind and supportive aunt or uncle can help to maintain a normal routine and a safe and understanding environment for the surviving siblings.

Individuals and families grieve within broader cultural contexts. Some turn to culture and tradition to find support and comfort in the answers, rituals, ceremonies, behavioral prescriptions, and spiritual practices they provide. Others do not strongly identify with the beliefs and mores of their cultures of origin, even when other members of their own family may do so. Too often culture is thought of in prescriptive ways, as if to say that we expect a member of a given community to express and process grief in the manner typical of that group. Surprisingly little attention has been paid to learning about the experiences of families from diverse cultural backgrounds when their child is seriously ill and dies. This seems a remarkable oversight, since it is broadly recognized that cultural values, beliefs, and practices play a central role in shaping how families raise and care for their children not only when they are healthy, but especially when they are seriously ill. It is important to find out what each individual family member believes about the nature of death, the rituals that should surround it, and the expectations about afterlife. As well, we must remember that our modern health care systems, hospitals in particular, have their own cultural mores, which may be in conflict with the cultural beliefs and practices of families in pediatric palliative care.

Watching a child fall sick and die is a crisis of meaning for families, and it is through their cultural understandings and practices that families struggle to explain and make sense of this experience. In fact, though research is sparse on the topic, there are some universal themes across cultures. One is the use of ritual and ceremony, and the other is the struggle for meaning and the questions that come to all bereaved families, whether they are whispered or cried out loud: “Why did my child (my sister, my brother, my grandchild) have to die?” “Where is the child now?” and “Will I ever see her again?” Spiritual or religious rituals may help families find meaning when their child dies, but for some families, some such rituals have the potential to interfere with the expression of grief.

**Situational Factors**

Situational factors refer to characteristics of the situation or the circumstances surrounding the child’s death. These variables include, for example, characteristics of the child’s illness, such as its duration, and of the death, such as the cause and place of death, and the extent of involvement in death-related events.

**Characteristics of the Child’s Illness and Death.** Where or when a child died, decision-making about the death, memories of sights and sounds, degree of medical intervention, and the cause of death are all subject matters that families discuss during bereavement while exploring their grief. Ideally, the
location (home or hospital) of a child’s death is based upon the family’s specific needs and requests, but circumstances (insurance issues, nursing shortages, transportation issues) may preclude achieving this goal. Long-term outcomes for bereaved parents and siblings of home-care deaths suggest an early pattern of differential adjustment in favor of home-care deaths.20,21

Decisions at the end of life, such as withdrawal of life support, may have been made with parents feeling they had insufficient understanding of the situation. Lasting images or smells may be comforting or concerning to families depending upon their associations. In fact, pain or other distressing symptoms the child might have experienced provide powerful material for families to struggle with during their grief. A full code that ends with the child’s death is very different than if a child slips into death from an unconscious state. Years of treatment followed by death is experienced very differently than one in which a child dies quickly.

Involvement in the Illness and Death-related Events. Growing consensus supports informing children about their medical condition and involving them in discussions and decisions about their care, appropriate for their levels of cognitive and emotional maturity.22–24 The same is true for involving siblings in the care of the ill child and in the events surrounding the death, such as the funeral, memorial service, and burial rituals. In one study, children who were more involved in such activities had fewer behavioral problems following the death.14 At the same time, practitioners must consider not only the individual child’s capacity for involvement, but also the family’s values about discussions of death, medical care, and children’s roles.

Models and Theories of Grief

From Freud to the current day, several theories and models have been developed that offer conceptual frameworks for how grief manifests in human beings. It is not the purpose of this chapter to provide an in-depth description of these various theories and models, since that content is covered elsewhere within this text. But, since nursing practice is guided by such theories and models, it is important to outline the development of thinking about bereavement as a basis for implementing best practices. Theories and models of grief can be categorized into stages and phase models, medical models, and task models.

Stage and Phase Models of Grief

Models of grief based on stages and phases work on the premise that there is a beginning and an end to the grief process, with some amount of sequential progression through grief. Among stage theorists are Lindemann,25 Bowlby,26 Engel,27 Kubler-Ross,28 Parkes,29 and Rando.30 Common patterns among these theories are the sequential nature they suggest and the emphasis of the physical, emotional, behavioral, social, and intellectual impact of grief.

Medical Models of Grief

Some models of grief liken the process to that of healing secondary to disease, injury, or psychiatric illness. Lindemann,25 Engel,27 Parkes,29 and Rando30 are among those who discuss issues of symptoms, management, or need for clinical attention with complicated forms of grief. Beverly Raphael31 urges that although pathological complications in grieving may be more readily equated with illness, the medical analogy is more difficult to sustain with uncomplicated grief. The overall process is articulated as a form of healing that might include issues such as helplessness, resistance to the reality of the death, preoccupation with the deceased, or identification with the deceased.

Stage and medical models have been subject to numerous criticisms in recent years. In particular, they do not capture the diversity of how we experience grief, either from an ethnocultural approach or from the perspective of the individual. Both types of models erroneously suggest that we come to an end in our grieving as we complete uniform or predictable stages or at last recover or reach “acceptance.” In truth, the questions of what happens after death or what is the meaning of life are never-ending existential mysteries for all of us. And these models imply that grief is a passive response to loss, when, in fact, grief is hard work.

Task Models of Grief

Lindemann25 was the first to coin the phrase “grief work,” and he identified three tasks: relinquish attachment to the deceased, adjust to life without the deceased, and develop new relationships. Parkes and Weiss33 and Worden13 have also developed task models, with a central theme being the need to loosen ties to the deceased. Attig34,35 describes the work of grieving as an active process of relearning the world, including physical surroundings, social surroundings, aspects of self, and the relationship with the deceased.

Of interest, the only model that specifically addresses grief in children is Bowlby’s model, but not only do his three phases suggest a time-limited process, they also downplay the potential long-term impact of childhood bereavement. Attig’s model of relearning the world may come the closest to describing how adults, as well as children and adolescents, relearn the world by summing the many smaller tasks that together make up the complex nature of living with grief. A bereaved parent may return to normal life functioning, but is never finished loving or remembering his or her child. Even if the characteristics of that grief modulate over time, there may well be some form of heartache when that child is present in parental thoughts decades after the death. In the words of a bereaved mother, “I buried my child in my heart. I will always be with him anytime and everywhere.” Attig asserts that we relearn the world as whole beings, not all at once, but rather piecemeal in distinct and growth-filled encounters. Such a description aptly applies to bereaved children—they cannot take in the whole event at once, and only over time, with their whole beings, do they relearn their worlds.
A central question is how parents and other family members manage the relationship with the child who died. Given that the child is no longer physically present, what do parents, grandparents, aunts, uncles, siblings, or friends do with the bonds, feelings, thoughts, and past experiences with that child? Research studies document that grievers do, indeed, maintain lasting connections with the deceased. In fact, nurses can do much to facilitate these ongoing connections by offering to assist the family to obtain a memento of their child, such as a lock of hair, a foot or handprint, a photograph taken in the hospital, a piece of artwork, or a poem written by the child.

Impact of Grief and Bereavement on Family Members

Dying Children

Children react to their own dying as they do to most of life's experiences—within their cognitive and emotional capabilities. They live and die as children, but often with much apparent wisdom, sometimes seeming to surpass that of their adult caregivers. One of the earliest studies of seriously ill children indicated that very ill children are, indeed, aware of death and are more anxious than children hospitalized for nonserious illnesses or nonhospitalized children. Bluebond-Langner, based on her ethnographic study of dying children, subsequently described a process of how they become aware of their own impending death (Table 54–1). The children may experience a wide range of feelings, including but not limited to anger, anxiety, sadness, loneliness and isolation, and fear. Behaviors may include avoiding the deceased fellow friends' names or staying away from their belongings; reducing attention to non–disease-related chatter and play; being preoccupied with death and disease imagery, particularly in play; engaging in open talk about the death only with selected persons; feeling anxious about weakened body functions and doubts about going home; evading talk of the future; being concerned with things being done right away; regressing, such as refusing to cooperate with relatively easy, painless procedures; or having estranged relationships with others, demonstrated by anger or silence.

Of course, we need to recognize individual variations within the above patterns, but this work provides some background

| Stage I: | An ill child's parent is shocked to face the disastrous diagnosis of his or her child. Ill children cannot be answered honestly as to what is happening to them because their parent, and even health care providers, tend to hide the worst information. Children feel that all answers from adults are not fully understandable. Children feel as if they are in the dark—“in a fog.” Lastly, ill children conclude that others’ responses are not like they were before, when they were sick with a simple disease. They guess themselves that they are “seriously ill,” or “very, very sick.” |
| Stage II: | When status is uncertain, the children may see their relatives crying even though they are becoming accustomed to the hospitalization with the serious disease. The children also feel that their family members give them special treatment. In addition, they still suffer from some procedural pain. They are less socialized with healthy peers, and they would rather have an opportunity to join a group of ill children in any treatment setting. Through play and talk with fellow patients, they get to learn about their disease and acquire information related to the disease experiences. |
| Stage III: | Based on the characteristics of chronic or life-threatening conditions, children experience remission and recurrence by turns. Every relapse repeatedly baffles them. They may continually take cues from their parents’ behavior, often overhearing conversations between health care providers and their parents about their disease process. Their knowledge on the purposes and implications of specific treatment procedures is markedly increased. In particular, health care staffs’ refusals to elaborate or vague responses such as “Well, we will see . . .” or “I don’t know . . .” erode the provider’s credibility. Experiencing several recurrences, many seriously ill children begin to think that their sense of well-being is fading. |
| Stage IV: | They are increasingly aware of being different from their healthy peers. In particular, their world is rapidly transformed by the disease culture due to their disease. The biggest problem to them is the deprivation of the school experience. As sick children, they doubt they will ever get better. To them, the illness is seen as a permanent condition. |
| Stage V: | They know the limitations of medication to cure their disease. Gradually, they can estimate a definite end, death. |

Parents

Parent-child relationships are not contractual, but sacred. They are unique and complex. The connectedness between parent and child has its roots in the biological and emotional bonds and attachments that precede birth. It grows as the parent begins to know and care for the child. The child is a parent’s link to the future.39 Parental grief is all-consuming, affecting every aspect of parents’ existence.

Parents often struggle with guilt following their child’s death due to deep-rooted feelings of responsibility for their child’s welfare. Since parents are responsible for protecting and sustaining their children, shielding them from all danger, many parents feel they should have protected their child from illness and death. When children die from an inherited disease such as cystic fibrosis or sickle cell anemia, parents know their child’s condition results from their unknowingly passing on the genetic material. When the child dies, parents may still carry the burden of knowing they “gave” their child a terminal illness. Parents whose child died from an accident may also feel guilty for abdicating their protective role. Bereaved parents may cling to irrational guilt since it is often easier to accept blame, with its fantasy of control, than the total loss of control with which they must grapple. Or, they may blame someone else for their child’s death. Sometimes this guilt is targeted toward a partner or spouse, another child or family member. Nurses need to be aware of these dynamics and help a family find an appropriate place for their anger and blame.40

Parents, as individuals, may have different styles of grieving as described earlier. Nurses can help by acknowledging the “normality” of a variety of grieving styles and encouraging parents to understand each other’s ways of grieving. Differences in bereavement response also may lead to a strain on the couple’s sexual intimacy. Sexual abstinence is frequently reported by bereaved couples due to a lack of sexual interest; others seek out comfort through sexual intimacy. Again, pointing out that such reactions can be expected may help couples realize the “normalcy” of their reactions. A long-standing myth is that divorce rates among bereaved parents are very high. In fact, it is not higher than the national divorce rate. And, when divorce follows a child’s death, it is usually due to problems that existed before the child’s illness or death.

Nurses must also be cognizant of the special needs of bereaved parents who cope with additional stressors in their everyday lives. Single parents, or same-sex parents may not have as many options for support as married parents in a heterosexual relationship.

Moreover, nurses must pay attention to the indirect grief of parents who witness or coexperience the death of other terminally ill children in the same clinical setting as their child.41

Grandparents

The grief of grandparents is two-fold: they have to bear their own grief, as well as bear the agony of the grief of their own child, the parent of the deceased child. Grandparents can be a source of considerable strength for parents and siblings, or they can be an additional source of stress. Their advice may be sought but then ignored; often their practical help is accepted, but their own grief is barely acknowledged.2 Grandparents may experience considerable helplessness and frustration; they question the meaning of life as they struggle with the “lack of order” of having the young one precede them in death.

Siblings

Siblings have been called the “forgotten griever.” They have been typically ignored when a brother or sister dies, not for lack of parental concern, but because their parents are so overcome with grief, they have little energy to devote to the needs of their surviving children. The impact of a child’s death on surviving siblings is manifested in four general responses, best characterized in the words of the children themselves:14 “I hurt inside,” “I don’t understand,” “I don’t belong,” and “I’m not enough.” Not all children who have a brother or sister die experience all four responses, but most children through to adolescence demonstrate all responses to varying degrees.

“I Hurt Inside.” The first response includes all the emotions typically associated with grief—sadness, anger, frustration, loneliness, fear, guilt, restlessness, and a host of other emotions that characterize bereavement. Unlike adults who are able to talk about their responses, children manifest their responses in various behaviors, such as withdrawing, seeking attention, acting out, arguing, fear of going to bed at night, overeating, or undereating. In response to children who are hurting inside, nurses need to allow, and even encourage, the expression of the hurt the children are feeling. They may endeavor to share their own thoughts and feelings with the children to let them know that they are not alone in this situation. If adults do not allow children to express their feelings, siblings learn there is something wrong with such feelings. When adults are impatient with children, or belittle their expression, siblings learn to stifle their feelings.

“I Don’t Understand.” Children’s difficulty in understanding death is greatly influenced by their level of cognitive development. However, once children know about death, their cognitive worlds are forever altered. If they are not helped to understand what has happened in clear, simple, and age-appropriate ways,
children make up their own explanations that usually involve taking responsibility for the death and their parents’ distress. Without explanations, they become more frightened and insecure. Nurses must have a solid grasp of children’s cognitive development, provide appropriate explanations for events that happen, and be open to questions from children.

“I Don’t Belong.” A death in the family tears apart the usual day-to-day activities and patterns of living. Parents are overwhelmed with their grief, with making arrangements, and with caring for their other children. Surviving children are overwhelmed with the flurry of activity and the depth of emotion surrounding them. They often feel as if they don’t know what to do; they may want to help, but they don’t know what to do, or, if they try, their efforts are not acknowledged. They begin to feel as if they are in the way, or as if they are not a part of what is happening. They feel different from their peers as well, and begin to feel as if they don’t belong anymore. Nurses can play a critical role in including siblings in illness- and death-related events, such as encouraging or teaching the child to participate in certain treatments (for example, by holding their sibling’s hand or blowing bubbles together during painful procedures). After death, the nurse can help the parents by modeling what to say to the children.

“I’m Not Enough.” Assuming that they are somehow responsible for their parents’ distress, siblings may feel as if they are not enough to make their parents happy ever again. They may feel that their deceased brother or sister was the favorite child, and they should have been the ones to die instead. Some siblings respond by striving to be as good as they can be, trying to prove that they are worthy. They must be made to feel special just for being themselves, and by not comparing them to their deceased brother or sister. Moreover, siblings may not want to burden their parents with their grief, knowing their parents are already overladen. Nurses can assist siblings to feel special by asking them questions about their lives and reassuring them of their value and unique characteristics or abilities.

Adolescents

Teenagers who are dying, or who are the siblings or friends of another child, are often overlooked. They face a particularly complicated situation when they encounter death and bereavement because adolescents are typically engrossed in achieving independence and in proving their invulnerability. Serious illness and grief catches them by surprise, as they seldom have developed the coping skills necessary to deal with their reactions. As well, many adults believe it is difficult to help adolescents cope with death because adolescents are reputed to turn away from adults and to talk only with other adolescents. This is not entirely true, as these young people often seek out and value the input and support of adults they respect, such as a teacher, a nurse, or a friend’s parent. Moreover, when adolescents turn to their peers, if they do, they may often find that their peers have no significant resources to offer because they too are inexperienced with death.

Dying adolescents with a terminal disease struggle against physical pain, are sensitive to their parents’ reactions, and have a strong desire to have relationships with their friends regardless of their illness status: “I couldn’t say anything with my Mom. She pretends to smile to me, but I know how she feels so sad whenever looking at me. I want to come out and share my emotions with my friend at least. But, now there is nobody around me.” In such cases, nurses are in a position to help an adolescent’s family members to understand adolescent cognitive and psychosocial functioning. Self-help support groups for teens, either in person or via the Internet, often prove valuable to grieving adolescents. Adolescents are often open to writing, art, or music. Adults may come along on such journeys, or share the results, but they should take care to follow the adolescents’ lead, respecting confidentiality and permitting them to interpret the significance of their work in their own way.

Assessing Grief

Bereavement care is interdisciplinary in nature, focusing on assessment of the comprehensive pattern and character of the whole family, as well as of individuals within the family. Grief assessment focuses on the ill child, other family members, and their significant others. Grief assessment begins when the child is admitted to the hospital or at the time of diagnosis of acute, chronic, or terminal illness. It is ongoing throughout the course of the child’s illness and comes to the forefront during the bereavement period after the death. Nurses, in particular, play a central role in a family’s initial bereavement experience. Most children’s deaths still occur in the hospital; nurses are most often present at the time of death. If not with the child at the moment of death, the nurse is usually the first one called to the child’s bedside. The nurse’s words and actions at that time leave indelible imprints upon parents. Even years after their child’s death, parents recall vivid memories of the nurse’s gentle approach in offering privacy, giving a hug, sharing the sadness, allowing families the amount of time they want with their child before leaving the hospital. Unfortunately, other parents remember the nurse who spoke abruptly to them, or rushed them away because their child’s room had to be made ready for the next patient. In even these brief interactions, nurses can do so much to prevent this devastating experience from being any worse than it already is for the family.

In assessing grief, clinicians should keep in mind the range of factors that impact upon the grief of family members, while noting those factors that put individuals and families at risk for disenfranchised or complicated grief. The passage of time is not a useful consideration in assessing grief responses; instead, we must assess the degree of intrusiveness into each individual’s life and the extent to which family members can carry out their usual activities.
Helping Bereaved Families

Grief assessment leads to a plan of care with the goal of facilitating and supporting the grieving process. Understanding grief as a normal, human process that is individually expressed enables practitioners to present an accepting, nonjudgmental attitude that helps create a respectful and trusting milieu. The approach to children or other family members experiencing anticipatory grief is the same as for family members whose child has died, but the focus of some interventions may differ. For example, prior to death, families should be offered information about the signs and symptoms of disease progression and the dying process; following death, the focus may be on listening to family members review the course of the child’s dying.

Grief Interventions

For Families

Bereaved individuals need an opportunity to express their grief in a supportive environment. Nurses have a responsibility to create such an environment for parents and other family members following a child’s death so that they feel it is okay for them to express whatever they are feeling. Such comments as “It must be very difficult for you right now” give permission for expression. The form of expression may vary among family members; some will verbalize, others will cry, some may leave the room. Still others may express anger, and others appreciation.

Nurses may fear “saying the wrong thing” to a family member, or may fear not knowing what to say, or feel they must have the “right thing to say.” Attitudes are conveyed through words and more importantly, through actions. Thus, it is usually best to say very little, avoiding clichés and euphemisms that can be so distressing to grieving individuals. It is not appropriate to encourage anyone to “Keep a stiff upper lip” or to “Look on the bright side.” It is disrespectful, and even cruel, to say “He is no longer suffering” or “You are young—you will have more children.” These messages, whether given directly or indirectly, may compound the pain by making family members think the clinicians do not understand their loss. Instead, sit or stand quietly close to the family, let them know they can stay with their child for as long as they would like, comment on the child’s special qualities and acknowledge your own sadness about the child’s death. Offering to help in practical and concrete ways is also helpful. However, rather than asking if “there is anything I can help you with,” offer to do specific things, such as making phone calls or getting them a glass of water. Most family members have a need to share their story, telling and retelling anecdotes about the child and the events of his living and dying. Listening to their stories is probably the most helpful action. For some families, reviewing what happened with their child with the care providers is critical.

Follow-up phone calls or visits with the providers who cared for the child are much appreciated by families.

Many family members who are unaware of the normal manifestations of grief can find some comfort in knowing that their pain is normal. Providing information about the common facts of grief can be helpful; having written materials to send home with families is even better. Understanding that each person’s grief experience is unique helps family members understand that there is “no right way to grieve.” It also helps them to realize they are not “bad” or “crazy” if they express their grief differently from other family members; it also may prevent family member from telling other family members how they “should” grieve. Clinicians should identify any need for additional assistance and make referrals as needed. For example, a family member may have spiritual concerns that would be best addressed by the pastoral care person; a social worker may assist with funeral arrangements or financial concerns. In addition, the nurse should make referrals to bereavement specialists, psychologists, or physicians as needed.

For Children

Since grief is a human response, children and adults alike feel denial, anger, sadness, guilt, longing in response to a loved one, and experience lack of sleep, lack of appetite, and difficulty concentrating and maintaining usual patterns of interaction with others. However, most children have limited ability to verbalize and describe their feelings; they also have very limited capacity to tolerate the emotional pain generated by open recognition of their loss. Moreover, children’s cognitive developmental level interferes with their ability to understand the irreversibility, universality, and inevitability of death, and to understand the reactions of their parents. They also deeply fear being different in any way from their peers, and so are often unable to find comfort, as adults do, in sharing their discomfort with their friends. As play is the work and the language of childhood, children are able to express their feelings through their play, as well as music and art. A summary of grief reactions in children, according to age level, and corresponding suggested interventions, is presented in Table 54–2.

For Parents

Before the child’s death, an important emphasis for clinicians is to facilitate connections between the parents and the ill child and their other children, as well by helping them develop memories and keepsakes that they can hold and cherish long after the death. The earlier these can be collected, the better, so they reflect a longer period of time with the child and not simply the final days of life. Facilitating communication between family members and the caregiving staff, as well as among family members themselves, also creates positive memories and optimal coping. Informing parents about the dying process, and helping them with the concept of appropriate death consistent with patient, family, cultural, and spiritual goals is necessary. Assisting with planning funeral or memorial services

also can be helpful, particularly for families who have limited support systems.

After the child’s death, follow-up by the clinicians who cared for the child is much appreciated by families. Such follow-up also allows ongoing assessment (See Table 54–3 for questions to ask during an initial follow-up telephone call). Parents, overcome with their own grief, may need assistance in dealing with the needs of their other children; encourage parents to enlist the support of aunts, uncles, or good friends in this regard. For parents who are willing and interested in finding additional support, provide a listing of parental support groups and other parent bereavement resources in the community, such as Compassionate Friends, a self-help organization to help parents and siblings after the death of a child (http://www.compassionatefriends.org).

Bereavement Programs

The development of pediatric palliative care programs, including bereavement programs, in health care institutions has increased notably in the past decade despite budget and other resource concerns. Still, the dearth of consistency and excellence in both the training of professionals and the offering of services to families results in many gaps in the experiences of families. Such gaps must be addressed, especially for families of children who had a chronic illness that meant frequent trips to the hospital, sometimes over many years, and resulted in the development of close relationships with staff members. Such families worry that the staff will forget their deceased child; some families want to maintain an ongoing relationship with those who cared for their child. Thus, during the transition after the child’s death, families and staff have to navigate the changing relationship. A bereavement program within pediatric palliative care, or as part of an agency-wide program, can be of considerable service to both families and staff. Such

Questions for an Initial Follow-up Telephone Call to Parents Who Have Experienced the Loss of a Child or Perinatal Loss

“Your might recall that you were told that someone from the hospital would call you in (number) weeks...”

“Is this a good time to talk?”

“Are there any issues that you have been thinking about that perhaps I could follow-up on for you?”

“Have you been back yet for a postpartum check-up?”

“Some parents have noticed a change in their sleeping or eating habits. Has this been a problem for you?”

“How has (name of other parent) responded to your loss? Sometimes it is hard for both parents to talk about it. How has it been for you?”

“Do you have other family members or friends that you have been able to talk to? What types of things have they been able to do for you?”

“Do you have plans to work outside of your home? The first few days at work can be especially difficult. Have you thought about how it might be for you?”

“Did you receive any information on support groups for parents?”

“Are there any other materials you received in the hospital that you have questions about?”

“Are there any other questions I can answer for you?”

“During the call you stated that...”

“I will call you again on (date).”

a program facilitates referral of families to grief therapists as needed, ensures that all families are made aware of the available services, such as support groups, memorial services, or grief workshops. These services also facilitate bereaved families connecting with the staff who cared for their child, and most importantly, with one another as a source of support. The existence of a bereavement program gives a clear message that an institution and its staff are committed to the care of families.

The Nurse: Death Anxiety, Cumulative Loss, and Grief

Professionals who help children and families with the serious illness and death of a child are witness to numerous heart-wrenching scenes, and are constantly reminded of the frailty and preciousness of life. Working with dying children can trigger nurses’ awareness of their own personal losses and fears about their own death, the death of their own children, and mortality in general. Historically, nurses and other health care professionals were taught to desensitize themselves to these experiences and to maintain an “emotional detachment.” This approach, which still exists today in many situations, results in the nurses’ use of defenses to allay their fears, including focusing only on physical care needs, evading emotionally sensitive conversations with children and families, and talking only superficially about topics that are comfortable for the nurse. These behaviors result in emotional distancing, avoidance, and withdrawal from dying children and their families at a time when children most need intensive interpersonal care and active involvement by the nurse. Death anxiety occurs when clinicians are confronted with fears about death and have few resources or support systems to explore and to express thoughts and emotions about dying and death. Thus, rather than a “desensitization” of oneself, professionals are encouraged to sensitize to this powerful human material. Caring for dying children requires nurses to explore, experience, and express their personal feelings regarding death. Personal death-awareness activities and exercises, discussion of belief systems about death/afterlife with friends and colleagues, self-exploration, and reflection may promote an understanding and acceptance of death as part of life. The process is complicated by cumulative loss, a succession of losses experienced by nurses who work with patients with life-threatening illness and their families, often on a daily basis. When nurses are exposed to death frequently, they seldom have time to grieve one child before another child dies.

Harper has put forth a model of how professional caregivers learn over time to move through the pain of providing this kind of care. Her five-step model (Table 54–4), about caring for dying children, starts with intellectualization of the experience, and is characterized by attainment of knowledge and anxiety about performance. She goes on to describe caregivers moving through emotional survival, depression, and emotional arrival. Finally, and only after working through the personal pain of grief work, caregivers arrive at a place of deep compassion for families, characterized by self-realization and self-actualization on the part of the caregiver. Self-awareness about one’s own personal history of loss is necessary to know one’s own set of beliefs about death, dying, and the afterlife. Without this awareness, our own beliefs and cultural/spiritual biases can interfere with the experience of the family. For caregivers, strong coping techniques, good self care and ongoing education and support are necessary components to not only do the work, but also to avoid burnout.

Several factors influence nurses’ adaptation to the inherent grief in pediatric palliative care. They include the nurses’ professional training and other training in dealing with dying, death, and grief; nurses’ personal and professional history of loss and possible unresolved issues of dealing with grief; personal and professional life changes; and the presence or absence of support systems.

In one study of nurses’ experiences following the death of a child, participants described two types of distress. Moral distress resulted when the nurses knew the child’s death was imminent and were required to carry out painful treatments they perceived as unnecessary. Grief distress occurred in response to the child’s death. Both types of distress resulted from lack of open communication within the care team and lack of consideration of the nurses’ viewpoints. Thus, systems of support are critical to nurses’ coping with the stress of working with seriously ill children and their families. In addition to helping bereaved families, as mentioned earlier, institutional bereavement programs also serve the needs of staff. Programs can be structured to offer help in debriefing after a death, validating staff feelings, offering support groups, and encouraging informal support through the one-one-one sharing of experiences with coworkers, peers, or pastoral care workers. The presence of a supervisor, mentor, or instructor during the care of the dying, when a family member visits, or during the time of the child’s death can greatly decrease anxiety and provide immense support to the nurse, particularly to novice nurses in pediatric palliative care. Education that enhances knowledge and skills in end-of-life care can promote competence and self-confidence. Education that describes families’ experiences can be invaluable because it empowers clinicians to offer care that is more sensitive to the needs of families, more humanistic, and more family centered and thus, more rewarding to staff. Nurses have responsibilities for acknowledging their own personal and professional limitations, seeking assistance, and engaging in self-care activities.

Pediatric palliative care is a challenging field, one that demands finding the balance between providing compassionate quality care and personal satisfaction as a professional nurse. In addition, working with dying children and their families provides meaning to life. Working with these children helps to develop a clear perspective of what is really valuable; it helps us grow as persons and professionals. From the children and their families, we learn that death is part of life, that human beings are remarkably resilient, and that hope is everlasting.

### References

Key Points

- Pain assessment depends on the child’s age and cognitive developmental stage.
- Analgesic doses are initiated according to the child’s chronological age and body weight (milligrams or micrograms per kilogram).
- Pain management plans are based on the child’s past experiences, developmental level, present response, and physical, emotional, and cultural factors.
- The child and parent are the unit of care. Parental involvement is key to successful interventions. Parents/caregivers must be included in assessment and pain management plans.

Pain, a source of suffering, is present in many children—those who are facing a potentially life-threatening illness and those who are not. Expert pain management is a necessary part of pediatric palliative care.\(^1\) It is possible for very young children to feel and express pain. A child’s ability to communicate pain is influenced by age and cognitive level.\(^2\) Even a preverbal child can communicate pain. To effectively manage an individual child’s pain, the nurse first must be aware of the possibility of pain, sensitively observe the child, and use developmentally appropriate, objective assessments. Developmental factors (physical, emotional, and cognitive) play an important role in both pediatric pain assessment and pain management. Through knowledge of these factors and an awareness of how they affect an individual child, it is possible for nurses to effect better management of each child’s pain (Table 55–1). Despite a significant increase in interest and in the study of pediatric pain and its control over the last 20 years, there often remains a gap between what is technically possible and what is clinically practiced.\(^3\)

Definitions of Pain and Other Relevant Terms

There are two very useful definitions of pain. The first states that pain is “an unpleasant emotional experience associated with actual or potential tissue damage or described in terms of such damage.”\(^4\) The second, which stresses the subjective nature of pain and was stated by Margo McCaffery, RN, in 1968, is that “pain is whatever the experiencing person says it is, experienced whenever they say they are experiencing it.”\(^5\)

Nociception is “the perception by the nerves of injurious influences or painful stimuli.”\(^6\) This term is frequently used in discussions of pain in the neonate because of the challenges in evaluating the newborn’s ability to be conscious to the perception of pain. A neonate is a newborn baby who may be preterm or up to 1 month of age.\(^7\)
### Table 55–1
Questions to Answer When Evaluating a Child with Pain

<table>
<thead>
<tr>
<th>Useful Questions</th>
<th>Clinical Implications of Answers</th>
</tr>
</thead>
</table>
| What is the chronological age of this child? | Age-related physiological development affects pharmacokinetic and pharmacodynamic effects of medications.  
In the neonate, normal neuroanatomical and neurobiological developmental processes occur and allow for transmission of painful stimuli. |
| What is the developmental stage of this child? | Developmental age helps determine  
• How a child might express his or her pain  
• Which assessment tools may be useful  
• What cognitive-behavioral techniques might be considered |
| • Neonate  
• Infant  
• Toddler  
• Preschooler/young child  
• School-age child  
• Adolescent | |
| What type of pain does this child have? | The particular situation can guide the clinician to a developmentally appropriate assessment tool and a situation-specific pain management plan that includes both pharmacological and nonpharmacological interventions. |
| • Acute pain  
• Chronic pain  
• Procedural pain | |
| Does this child have a chronic illness? | Certain painful conditions have disease-specific, validated pain assessment tools. For example, the Douleur Enfant Gustave Roussy (DEGR) scale is available to assess prolonged pain in 2- to 6-year-olds with cancer. |
| Is this child neurologically impaired? | Cognitively impaired children may process information and communicate distress differently from normally developed children.  
Besides knowing the science, and the individual child, it may help to know other children with similar conditions. |
| | New pain assessment tools for children with intellectual disabilities are being validated to look at generic, procedural, and surgical pain. |
| Does this child and do the parents of this child speak the same language as the health care providers? | Find ways of obtaining translators  
Some pain assessment tools are available in translated versions  
It may be worth having pain assessment tools translated into languages common to certain practice settings. |
| What is the underlying cause of this pain? | If the underlying cause is treatable, the pain may be reduced or eliminated |
| What is the weight in kilograms of this child? | Dosage of analgesics is expressed in milligrams or micrograms per kilogram.  
For some medications, the starting dose depends on the child’s being larger or smaller than a set weight |

(continued)
Pediatric Pain: Knowing the Child Before You

One term that is frequently encountered in the subject of pediatric pain is procedural pain. Procedural pain is pain that is caused by procedures (e.g., needlesticks, heel punctures, lumbar punctures). All children who interact with the health care system potentially experience procedural pain.

Conscious sedation has been defined by the American Academy of Pediatrics as "a medically controlled state of depressed consciousness that (1) allows protective reflexes to be maintained; (2) retains the patient's ability to maintain a patent airway independently and continuously; and (3) permits appropriate response by the patient to physical stimulation or verbal command" (p. 1110).

Prevalence of Pain in Children

Clinicians working with children in the general pediatric area will encounter pain in children who are undergoing immunizations and procedures and those who have pharyngitis, oral viral infections, otitis media, urinary tract infections, headache, or traumatic injuries. Conditions such as meningitis and necrotizing colitis can cause pain in children. Children who experience chronic diseases such as cancer, human immunodeficiency virus (HIV) infection, sickle cell disease (SCD), juvenile chronic arthritis (JCA), and cystic fibrosis (CF) also will have pain. Definitive studies focusing on the prevalence of pain in the pediatric population are lacking. At best, we have studies that look at the incidence of pain in various disease subpopulations. Children with certain conditions are prone to particular pain syndromes. Nurses working with children need knowledge of the pain syndromes they may commonly encounter in the populations they work with and need to feel comfortable assessing and managing those particular pain syndromes.

Etiology of Pain in Children

Neuropathic Pain

Neuropathic pain is less common in children than in adults. Many of the neuropathic pain syndromes seen in adults are not seen as frequently in children. Children may experience neuropathic pain from migraine headaches, scar neuromas after surgery, phantom limb pain after amputations for trauma, tumors, meningococcemia, and complex regional pain syndromes (reported in preteen and teenage girls). Although diabetes is increasing in incidence in the pediatric population, it is rare to see a child who has diabetic neuropathy, a syndrome that takes years to develop. Brachial plexus avulsion, an injury that sometimes occurs to babies during childbirth, is thought by some to be less disabling and painful in babies than when it occurs (for other reasons) in adults. It is not clear whether this is due to inadequate assessment of infants or to the physical developmental functions of babies.

Burns

Burns, thermal injuries caused by hot liquids, flames, and electricity, are among the most common causes of injury to children and are associated with pain. This injury, which destroys the skin, can have significant morbidity and mortality depending on the extent of the burn. Intact skin is necessary for protection against bacterial infection, fluid and electrolyte balance, and thermoregulation. Treatment of severe burns is associated with
significant pain. Undertreatment of this pain can make it difficult for the child to cooperate with burn treatment. It is postulated that use in children of an individualized pain management plan with high-quality pain control components, such as intravenous opioids, local block, or even general anesthesia, can avoid the development of a postburn hyperalgesia syndrome caused by continuous or repeated stimulation of nociceptive afferent fibers.11

Cancer

As recently as 1998, the World Health Organization (WHO) stated that 70% of children with cancer will experience severe pain during their illness.12 The types of pain in children with cancer, whether caused by procedures, by the disease or tumor, or by anticancer treatment, have been well described for many years.12–15 A study by Ljungman and colleagues16 of children receiving treatment for cancer revealed that procedure- and treatment-related pain were significant problems initially and that procedure-related pain gradually decreased but treatment-related pain remained constant. In addition, children with cancer may have pain for unrelated reasons, such as acuteappendicitis.17

All children with cancer are at risk for procedural pain. Most procedure-related pain involves needle puncture. This procedure may be necessary for obtaining blood supplies, accessing implanted venous devices, administering intravenous chemotherapeutics, or giving intramuscular or subcutaneous medications. Lumbar punctures (using a spinal needle) or bone marrow aspiration (involving insertion of a large needle into the posterior superior iliac spine) are variations of needle puncture.13 Some children develop prolonged post–lumbar puncture headaches.12 Despite significant efforts to avoid needlesticks in the pediatric population, sometimes a needle puncture is necessary and cannot be avoided. Removal of tunneled central venous catheters or implanted ports also causes procedural pain and must be addressed by clinicians caring for the children undergoing this procedure.13

For some children, it is the experience of tumor-related pain that leads their parents to seek medical attention and eventual diagnosis. This pain can be nociceptive or neuropathic. Nociceptive pain can be somatic, caused by tumor involvement with bone or soft tissue, or visceral, caused by tumor infiltration, compression, or distention of abdominal or thoracic viscera. Neuropathic pain can be caused by tumor involvement (i.e., compression or infiltration) with the peripheral or central nervous system.

Most children who receive a diagnosis of cancer, no matter what the stage, will receive some sort of anti-cancer treatment. Frequently this treatment causes some sort of pain, either acute or chronic. Surgery leads to acute, postoperative pain. Removal of limbs may lead to the development of phantom limb sensations and pain. This experience is thought to decrease over time in children.13 Radiation therapy may lead to an acute dermatitis or pain. Children undergoing chemotherapy are at risk acutely for mucositis pain and gastritis from repeated vomiting (if nausea and vomiting are not successfully controlled)14 and chronically for neuropathic pain from certain chemotherapies. Children who have been treated with high doses of steroids are at risk for development of avascular necrosis, a disabling condition that eventually causes the affected bone to collapse. Some chemotherapies, such as vincristine, asparaginase, and cyclophosphamide, can cause pain or painful conditions such as peripheral neuropathy, constipation, hemorrhagic cystitis, or pancreatitis. Complications of intravenous chemotherapy administration may lead to pain from irritation, infiltration, extravasation, tissue necrosis (if vesicants are used), or the development of thrombophlebitis. Children receiving intrathecal chemotherapy may develop arachnoiditis or meningeal irritation, also painful conditions. The child who is immunocompromised, whether from chemotherapy or from disease, is at risk for infection and infection-related pain. Skin, perioral, and perirectal infections are common. Children seem to be at less risk for acute herpes zoster and its related pain.13 Bone marrow transplantation may lead acutely to severe mucositis and potentially to chronic graft-versus-host disease, which may manifest as severe abdominal pain if it effects the gastrointestinal system.13

Medications used to prevent or modify side effects of primary disease treatment can have painful effects. Use of corticosteroids in disease treatment may lead to bone changes that cause pain.12 Colony-stimulating factors may lead to medullary bone pain shortly after administration and before the onset of neutrophil recovery.

Nurses caring for patients receiving new treatment protocols need to be alert to the development of pain syndromes associated with particular agents. For example, in recent years, the use of 3F8, an anti-ganglioside monoclonal antibody, in the treatment of advanced neuroblastoma has significantly improved survival but causes an acute episode of neuropathic pain affecting random body parts during infusion.13 As more is known about the effects of new treatment agents, more effective preventive measures can be taken to improve the quality of life of children undergoing potentially life-sustaining or life-extending therapy.

As children live longer with cancer, they may live longer with pain. Pediatric tertiary care centers, such as Children’s Hospital of Boston, have reported a variety of chronic pain problems, including causalgia of a lower extremity, chronic lower extremity pain caused by a mechanical problem with an internal prosthesis, and avascular necrosis of multiple joints in long-term survivors of childhood cancers.13

Human Immunodeficiency Virus Infection

Children with HIV infection may experience pain for a variety of reasons, including disease, treatment, and procedures. Some factors are quite similar to those associated with cancer-related pain, and some are unique to HIV disease. For example, children with the acquired immunodeficiency syndrome (AIDS) may have abdominal cramping pain due to AIDS-associated diarrhea.9
Sickle Cell Disease (SCD)

One of the most common genetic diseases in the United States, commonly affecting individuals of African, Middle Eastern, Mediterranean, and Indian descent, is highly associated with a variety of painful conditions. SCD is characterized by a predominance of hemoglobin S (HbS), which becomes sickle shaped (as opposed to donut shaped) after deoxygenation. It is this stiff, sickle-shaped red blood cell that becomes trapped in small blood vessels, leading to vaso-occlusion, tissue ischemia, and even infarction.17

Some of the many painful states that are commonly associated with SCD include acute painful events, acute hand-foot syndrome, acute inflammation of joints, acute chest syndrome, splenic sequestration, intrahepatic sickling or hepatic sequestration, avascular necrosis of femur or humerus, and priapism. The reader is directed to the American Pain Society’s Guidelines for the Management of Acute and Chronic Pain in Sickle Cell Disease28 (pp. 3–7) for a review of the clinical signs and symptoms of these and other common SCD pain states, their underlying causes, and special features or considerations. These episodes can vary in frequency and severity among and within individuals with SCD. Although most would be considered to be frequently recurring acute pain episodes, some, such as those caused by vertebral collapse or avascular necrosis of the femoral or humeral heads, can lead to chronic, debilitating painful conditions. A child with SCD may require hospitalization for pain control. A multicenter study by Platt and associates19 showed that 39% of patients with SCD had no pain episode that required hospitalization, whereas 1% had to be hospitalized for pain more than six times in a single year. For patients 20 years of age and older, being hospitalized more than three times per year for pain is associated with an increased incidence of death.18

Juvenile Chronic Arthritis (JCA)

In 2002, at least 285,000 children in North America were affected by JCA, a condition associated with acute and chronic pain and dysfunction. Disease severity or activity does not predict the intensity of pain that a child with JCA may experience. Children with arthritis may have fewer joints affected and may report less pain, compared with adults. A small percentage may even have painless arthritis. The goal of JCA treatment is to manage the pain and to lessen future problems with joint destruction. A child with JCA may experience procedural pain, acute treatment-related pain (e.g., gastritis), or chronic pain from compression fractures or avascular necrosis.20 Cassidy reported that chronic pain syndromes in pediatric rheumatology have increased during the last 25 years.21

Cystic Fibrosis (CF)

CF, an eventually fatal genetic disease that is diagnosed in 1 of every 3000 live births, has a different trajectory than other lethal childhood diseases. Throughout their lives, children with CF simultaneously receive preventive care to preclude future complications, therapeutic care to reverse the progress of current lung disease, and palliative care to relieve symptoms. Because of advances in medical science, individuals with CF are living longer and longer. Although they are most frequently cared by pediatric specialists, individuals with CF may live to be 20, 30, or even 40 years of age. A study by Robinson and others22 retrospectively reviewed the care received by 44 patients older than 5 years of age with CF before their deaths from respiratory failure. Thirty-eight patients received opioids for chest pain or dyspnea or both. Although the pain present was not thoroughly described, the fact that it was noted is significant information for those who care for CF populations.

Other Conditions Associated with Pain in Children

Other conditions children experience that may be associated with pain include muscular dystrophy and other degenerative neurological diseases and severe dermatological conditions. Unfortunately, the prevalence, distribution, and description of pain syndromes in many life-threatening illnesses in children have yet to be determined. This shortcoming may be a result of assessment difficulties in infants, preverbal children, and children with communication impairments. Or, it may be a consequence of the often single-minded focus on cure. As clinical interest broadens to also include increased attention to the comfort of these children, it is hoped that the pain and its treatment will be better defined and practiced.9

Physiology and Pathophysiology of Pain in Children

Important factors relevant to the physiology and pathophysiology of pain are well covered in Chapter 6. Those working with children need to be aware of the normal neuroanatomical and neurobiological developmental processes that occur in neonates and allow for the development of transmission of painful stimuli (Table 55–2). It is possible to assess the severity of pain and the effects of analgesics in neonates. Neonates who do not cry, move, or show other behavioral response in response to painful stimuli may still be experiencing pain. It has been shown that increased neonatal morbidity may result from prolonged or severe pain. It has been shown that neonates who experience pain may respond differently to pain later on (e.g., pain from inoculation) than do those who have not experienced previous painful events.7

Assessment of Pain in Children

The assessment of pain in children is a dialogue between the clinician, the child, and the parents. Through a series of questions, the nurse learns who the child in front of him or her is and how best to address this individual child’s pain. To do this, nurses assessing pain in children, from preterm neonates through adolescents, need to be aware of barriers and other

influencing factors that play a role in accurate, developmentally appropriate assessment.

Barriers to pain control in children are similar to those in adults. They primarily relate to (1) lack of assessment; (2) inadequate analgesics; (3) incorrect attitudes or misconceptions by patients, their families, or health care providers about pain and its management; and (4) issues related to systems. Table 55–3 reviews these barriers in detail.

To best assess and manage a child’s pain, the nurse must ask a series of questions that lead him or her to better know who a particular child is. One of the first questions is, “What is the child’s chronological age and what is his or her developmental stage?” Is this child a neonate, infant, toddler, preschooler/young child, school-age child, or adolescent? Nurses who work exclusively with children know that the answers to these questions have a huge impact on how a child is approached. Nurses who do not may find the review of developmental stages and factors relevant to pain useful (see Table 55–2). The following two case studies may also be helpful.

### Case Study

**Michael, a 7-Month-Old with Severe Mucositis**

Michael is a 7-month-old with severe mucositis, and his story illustrates the challenges present in caring for a preverbal child with pain. He is admitted for pain management and total parenteral nutrition (TPN). When the nurse performs the initial assessment, Michael’s parents report that they had been giving him acetaminophen when he looked uncomfortable but it didn’t appear to help him. Michael is awake, crying in his mother’s arms; his mouth is open, and he is drooling thick secretions; he is tachycardic and tachypneic. Michael is prescribed a dose of intravenous morphine. When the nurse assesses him 30 minutes later, he is sleeping and appears to be more comfortable. He is later placed on patient-controlled analgesia (PCA), and after 48 hours he is playful and interactive.

### Case Study

**Jenna, a 7-Year-Old Undergoing Abdominal Surgery**

Older children like Jenna, a 7-year-old who is on day 2 after abdominal surgery, can give more detailed pain-related information during assessment. The nurse is called into Jenna’s room because her mother reports that Jenna is experiencing incisional pain. After ascertaining that Jenna is not developmentally delayed, the nurse uses the Numerical Rating Scale to assess her pain. Jenna rates her pain as a 7 out of 10. Her vital signs are within normal limits with the exception of her heart rate, which is 123 bpm. Thirty minutes after receiving the prescribed dose of morphine, Jenna appears

  *Misconception: infants and children do not feel pain in the same way as adults do*  
  *Misconception: Children unable to provide useful, accurate information about the location and severity of their pain*  
  Lack of knowledge about how to assess pediatric pain†  
  Challenge of pain assessment in preverbal or noncommunicating children  
  Choosing the correct population specific tool  
  Need for comprehensive assessment with pain etiology and contributing or modifying factors identified  
  Need to select most appropriate medications, doses, dosing intervals, and route of administration for situation  
  Nurses or parents may not administer the complete dose ordered or as frequently as ordered  
  Prescriber’s reluctance to send children home with the effective opioids that the child received while hospitalized‡  
  Pain control in children too difficult or time-consuming*  
  Lack of knowledge or incorrect knowledge of pharmacokinetics and pharmacodynamics of analgesics, especially opioids†  
  Lack of knowledge of the consequences of unrelieved pain†  
  *Misconception: Children can tolerate pain better than adults can (this can lead to heightened pain and anxiety about pain control)*†  
  *Misconception: Children are at higher risk for development of chemical dependency from opioid analgesics and the use of opioids should be postponed despite severe pain*†  
  Fear of opioid-related side effects and lack of knowledge about how to manage them can also prevent appropriate use of opioids in children†  
  Need for systematic re-evaluation and reassessment of pain management plan’s effectiveness†  
  No systematic, evidenced-based approach to pain management despite rigorous approach to other aspects of a child’s care, including disease diagnosis and treatment  
  Lack of appropriate use of nondrug therapies to complement or supplement the pharmacological interventions† |

(continued)
comfortable, her heart rate is 100 bpm, and she rates her pain as a 2 out of 10.

Other influencing factors that may make the assessment of pain challenging are language or cultural differences between the child or family and the health care providers; the presence of chronic health conditions, development disabilities, cognitive, sensory, or motor impairments; and severe emotional disturbance. Factors that can complicate the communication between a child and the health care team increase the likelihood of suboptimal pain control.

In learning who an individual child is and what would work best in managing his or her pain, the nurse needs to talk with both the parents and the child. Although parents have varying abilities to recognize pain and its severity in their child, there is probably no one more sensitive to changes in their child’s behavior or more motivated in looking out for the health and well-being of a child than his or her parents. Hester and Barcus developed a series of questions for both the child and the parents that reviews the pain experience of a particular child. With the child, the nurse explores what pain or hurt is to this particular child, whether he or she communicates the pain to others, what relieves the pain, what the child finds helpful, what the child wants to avoid from others when he or she is in pain, and anything unique to how the child is when in pain. With the parents, the nurse explores the language a child uses and the behavior the parents observe when their child is in pain. The nurse reviews what painful experiences the child has had, how the child reacts, what tends to relieve a child’s pain (including what the child does and what the parents do for the child), and any other special information about the child when he or she is in pain. By using this questionnaire, a nurse is better able to get a complete picture of the child in pain.

Choosing an appropriate tool that will be useful in particular clinical situations can be challenging at best. In choosing a tool, the developmental age of the child should be considered first, and then the type of pain or medical situation or illness that the child will be experiencing. Attempts at measurement of pain include physiological measures, behavioral observations, and self-report measures. Physiological measures may reflect the response to the stress of pain and not the pain itself. Although they are far from ideal, physiological measures are often used in situations in which the child is unable to report pain for himself or herself. Acute pain is often associated with increases of 10% to 20% in noninvasively measured blood pressure, heart rate, or respiratory rate. These changes may not be present in the child with chronic pain.

Observational pain assessment tools, also used when a child cannot self-report pain, are criticized for possibly measuring distress behavior instead of pain behavior. Observational or behavioral scales are most often used in preverbal or cognitively impaired children. The pain behaviors specific to certain conditions may be useful, such as the observation of guarding, bracing, and active rubbing in children with JCA.

Self-report measures, by far the most preferable, can be obtained in some children as young as 3 years of age and generally by 6 years. Most pediatric self-report tools are not multidimensional and measure only pain intensity. To adequately report detailed ratings of pain intensity, a child, usually of school age or older, must understand the concepts of order and numbering. To test this knowledge, a child could be given six different sized pieces of paper and asked to place them in order from smallest to largest. If a 0-to-10 scale is used, with 0 being no pain and 10 being the worst possible pain, older children and adolescents may be asked to rate their pain with an number and then asked, “Do you consider your pain to be none, slight, moderate, severe, or excruciating?” The comparison between the child’s numeric pain rating and the categorical pain rating ideally will show some general agreement. Readers attempting to narrow their choices of pain assessment tools are referred to detailed reviews of pediatric pain assessment tools found in several references.

In any one practice setting, it may be necessary to use several tools because of the broad range of child development and cognitive disabilities that may be present. In the ongoing stress of pain and illness, a child may regress cognitively and

---

emotionally, which may necessitate the use of a simpler tool. This may also happen when a child is rendered cognitively impaired from medications administered. At present, there is a need for research that can make pain assessment tools more generalizable, with improvement of both specificity and sensitivity.

Assessment for pain begins with screening for the possibility of pain. This can occur in a systematic way every time a child enters a health care system, though the use of documentation tools that ask about the presence of pain. In addition to the collection of this information in an initial nursing database, hospitalized children may be screened more than once a day for the new development of pain or for the presence of unsatisfactory pain control. The so-called QUESTT approach to pediatric pain assessment is a self-explanatory one that summarizes the points stressed in this section and also leads to action and re-evaluation. A slightly adapted version consists of the following:

- Question the child and parent.
- Use pain rating scales appropriate to developmental stage of the child and to the situation at hand.
- Evaluate behavioral and physiological changes.
- Secure parents’ involvement.
- Take the cause of pain into account.
- Take action and evaluate results.

In every practice setting, a child with pain needs reassessment on a regular ongoing basis to improve or maintain the management of his or her pain.

**Management**

No matter what the practice setting, one of the main principles in pediatric pain management is to anticipate and prevent pain whenever possible. If that is not possible, the next principle is to minimize the pain by treating the underlying disease (if possible), using pharmacological and nonpharmacological modalities as appropriate, and choosing the least painful necessary procedures.

### Pharmacological Management

Nurses working with children with pain must be aware of age-related physiological trends that are relevant to analgesic action and have an impact on dosage prescribed. The physiological processes that are involved include the body compartments, hepatic enzyme systems for medication metabolism, plasma protein binding, renal filtration and excretion of medications and their metabolites, and metabolic rate, oxygen consumption, and respiratory function. Some of these developmental physiological changes and their clinical implications are presented in Table 55–2. Tables 55–4, 55–5, and 55–6 suggest starting doses for opioids and nonopioids that reflect these developmental aspects of pediatric pharmacology.

Although studies indicate that with proper age-related adjustments and dosing children can safely receive pain medication, it is important to bear in mind that approximately 50% to 75% of medications used in pediatric medicine, including analgesics, have not been adequately studied to provide appropriate labeling information. Clinicians who treat the pain of children have diligently tried to extrapolate data from experience with adults to determine what medications should be used and at what doses in children. This uncontrolled, undocumented, and unsystematic practice of off-label use, although well intended, is a systems problem that does not allow for medications used in children to be studied with sound scientific and ethical principles. It does not allow for the definition of age-dependent differences in pharmacokinetics and pharmacodynamics or for the establishment of which adverse events in children are similar to those in adults and which ones are unique to pediatric patients. This situation frequently occurs because of a result of lack of resources. The pediatric market is but a small segment of the total pharmaceutical market, and there is limited financial incentive to study medications in children.

There are three main groups of medications used to treat pain in children: (1) nonopioids (acetaminophen, nonsteroidal antiinflammatory drugs [NSAIDs], and aspirin), (2) opioids, and (3) adjuvant analgesics. Use of these medications depends on the severity and cause of pain in an individual child. The nonopioids and opioids are most helpful in the treatment of

nociceptive pain, and adjuvant analgesics work best for specific neuropathic pain. A general review of these medications and their use is presented in Chapter 6. What follows in this section are factors that are most relevant to the use of these drugs in children.

In 1998, the WHO published guidelines for cancer pain relief and palliative care in children. They stressed four key concepts of analgesic use in children: “by the ladder, by the clock, by the appropriate route, and by the child” (p. 24). "By the ladder" refers to approaching a child’s pain based on the presenting severity of pain, with steps clearly delineated for mild, moderate, and severe pain. For mild pain, nonopioids are indicated, with the addition of an adjuvant analgesic if a neuropathic contribution to the pain is suspected. If a child presents with or progresses to moderate pain, the nonopioid is continued (if not contraindicated), an appropriate adjuvant is used as a routine analgesic or antipyretic in neonates, infants, or children. Dosage guidelines for aspirin in neonates have not been established.

"By the clock" reflects the concept that for pain that is almost continuous a child will benefit most from nearly continuous analgesics administered on a regular schedule. This method promotes better pain control and decreases a child’s anxiety regarding uncontrolled pain. "By the appropriate route" promotes the administration of analgesics by the simplest, most effective, least painful route. For most children this is the oral route, but for some situations other routes may be more effective. "By the child" indicates the need for individualization of each child’s analgesic regimen. Starting doses listed on tables are just that—starting doses. Each child’s dose must be titrated up or down based on his or her response. If uncontrolled pain is present, opioids should be titrated upward until analgesic relief is obtained or unmanageable side effects occur.

Although the WHO guidelines were developed for the control of cancer pain, the four concepts can be applied to the use of analgesics in children in other painful circumstances.

### Use of Nonopioids in Children

Nonopioids (acetaminophen, NSAIDs, and aspirin) have a ceiling effect and cannot be safely titrated beyond the dose per weight given at drug-specific intervals. Pediatric dosage guidelines for commonly used nonopioid analgesics can be found in Tables 55–4 and 55–5.

Aspirin is not routinely used as an analgesic in infants and children because of the risk of Reye’s syndrome associated with its use in this population. The most widely used mild analgesic for children is acetaminophen. The recommended dosing of acetaminophen in children is based on the dose-response for antipyretic effects, because the pediatric analgesic dose response is unavailable. Currently there is no safety data on long-term acetaminophen use in children. NSAIDs have been shown to be safe and effective analgesics for children. Children using NSAIDs have been shown to have greater weight-normalized clearance and volumes of distribution than adults but with similar drug half-lives. Large-scale studies looking at the efficacy and risk-benefit and cost-benefit ratios of selective cyclooxygenase-2 inhibitors in children have yet to be done.

### Use of Opioids in Children

It takes until the age of 2 to 6 months for the weight-normalized clearance of many opioids to reach mature levels. Pharmacokinetic studies of morphine show an average serum half-life of

*The maximum daily doses of acetaminophen for infants and neonates are a subject of current controversy. Provisional recommendations are that daily dosing should not exceed 75 mg/kg for infants, 60 mg/kg for full-term neonates and preterm neonates of >32 wk postconceptional age. Fever, dehydration, hepatic disease, and lack of oral intake may all increase the risk of hepatotoxicity.

†Higher doses may be used in selected cases for treatment of rheumatological conditions in children.

‡Dosage guidelines for neonates have not been established.

§Aspirin carries a risk of provoking Reye’s syndrome in infants and children. If other analgesics are available, aspirin should be restricted to indications for which an antiplatelet or antiinflammatory effect is required, rather than being used as a routine analgesic or antipyretic in neonates, infants, or children. Dosage guidelines for aspirin in neonates have not been established.

Source: Berde and Sethna (2003), reference 29, with permission.
9 hours in preterm neonates, decreasing to 6.5 hours in full-term neonates and finally reaching 2 hours in the older infant. If not carefully monitored, neonates may be more likely to develop side effects from morphine due to decreased renal clearance of metabolites. The respiratory reflex response to hypoxemia, hypercapnia, and airway obstruction does not reach full maturity until 2 to 3 months after birth in both full-term and preterm infants. This can lead the nonintubated neonate receiving opioids to be at higher risk for ventilatory depression.29 Neonates receiving opioids or other agents that can compromise cardiorespiratory function must be continuously monitored in a setting that can quickly provide airway management. Those receiving prolonged opioid therapy may benefit from the use of continuous infusions to avoid the variation.

9 hours in preterm neonates, decreasing to 6.5 hours in full-term neonates and finally reaching 2 hours in the older infant. If not carefully monitored, neonates may be more likely to develop side effects from morphine due to decreased renal clearance of metabolites. The respiratory reflex response to hypoxemia, hypercapnia, and airway obstruction does not reach full maturity until 2 to 3 months after birth in both full-term and preterm infants. This can lead the nonintubated neonate receiving opioids to be at higher risk for ventilatory depression.29 Neonates receiving opioids or other agents that can compromise cardiorespiratory function must be continuously monitored in a setting that can quickly provide airway management. Those receiving prolonged opioid therapy may benefit from the use of continuous infusions to avoid the variation.
in plasma concentrations that occurs with bolus dosing. In neonates receiving synthetic opioids, the administration of infusions over several minutes or of small, frequent aliquots is recommended to avoid the adverse effects of glottic and chest wall rigidity that are associated with rapid bolus injection of medications such as fentanyl and sufentanil.7

When using opioids with infants, children, and adolescents, the goal is to control pain as quickly as possible. Repeated administration of small, ineffective doses that prolong the pain and worsen pain-related anxiety is to be discouraged. For moderate to severe pain, it is appropriate to use opioids such as morphine, fentanyl, and hydromorphone in optimal doses titrated to an individual child’s response.24 Initial pediatric opioid dose guidelines can be found in Table 55–6.

The following case illustrates how opioids can be given and adjusted for the benefit of an individual child.

**CASE STUDY**

**John, a Child with Neuroblastoma**

John, age 3 years 6 months, had progressive metastatic neuroblastoma. When his parents were told that his disease had returned and there was an experimental treatment available that would not cure him, they decided against the treatment. Their goal was for John to be comfortable and to keep him at home and hopefully alive until the birth of his new brother. When John started to complain of bone pain, his parents wanted him to receive pain medication. Opioid-naïve, he was started on morphine 0.1 mg/kg intravenously every 3 to 4 hours. As John’s disease progressed, so did his pain, and his morphine dose was escalated every 48 to 72 hours. He was eventually started on a morphine PCA pump, with dose escalation every 48 hours. Finally, the day arrived, and John became a big brother. At this point, he slept most of the day but had a few good hours of interaction with his family. He was able to hold his brother. His dose of morphine at that time was 200 mg/hour, with rescue of 75 mg every 10 minutes as needed. John died 7 days later, but his parents were thankful that he was relatively comfortable and was able to meet his brother.

**Use of Adjuvant Analgesics in Children**

Adjuvant analgesics are a heterogeneous group of medications that include psychostimulants, corticosteroids, anticonvulsants, antidepressants, radionuclides, and neuroleptics. Much of the evidence supporting their use in specific targeted pain syndromes comes from the adult literature. However, there has been some initial work looking at the use of adjuvants in children. The use of methylphenidate and dextroamphetamine in adolescents with cancer was reported to be safe, efficacious, and tolerable by Yee and Berde.31 Intraarticular injection of corticosteroids is one of the mainstays of initial treatment of most children with JCA.34 Although gabapentin has been studied as an anticonvulsant in children, it has yet to be investigated as an adjuvant analgesic in children despite widespread use as such.2 It is recommended that a child have baseline hematological and biochemical laboratory studies and an electrocardiogram performed to rule out Wolff-Parkinson-White syndrome and other cardiac conduction defects before initiation of tricyclic antidepressants and at periodic intervals if the child receives long-term therapy or exceeds standard dose/weight guidelines.32 One case has been reported of the use of 131 iodine-meta-iodobenzylguanidine to treat a boy’s bone pain caused by neuroblastoma.35 Future research in the use of adjuvant analgesics in the pediatric population is needed.

**Use of Local Anesthetics and Other Anesthetic Techniques**

In the past, local anesthetics were not widely used in children because of concerns regarding cardiac depression and seizures. Today, they can be administered by a variety of routes and have acceptable safety as long as the maximum recommended doses are adhered to. For bupivacaine, with or without epinephrine, the maximum recommended dose is 2 mg/kg for neonates and 2.5 mg/kg for other children. The maximum recommended dose for lidocaine in neonates is 4 mg/kg without epinephrine or 5 mg/kg with epinephrine. For children, the maximum recommended dose of lidocaine with epinephrine is 5 to 7 mg/kg.29

Intradermal administration of lidocaine can be used for skin anesthesia if painful punctures will occur. The lidocaine can be buffered with 1 part sodium bicarbonate to 10 parts 1% or 2% lidocaine to avoid the stinging effects of lidocaine administration. Several preparations of local anesthetics can be obtained for topical or transdermal administration to control procedural pain. Of these, eutectic mixture of local anesthetics (EMLA) is available as a cream or anesthetic disc. One hour before puncture, the EMLA cream is placed over the potential site with an occlusive dressing applied to prevent or minimize puncture pain. Lidocaine/adrenaline/tetracaine (LAT) or tetracaine/phenylephrine may be applied to open wounds for suturing, providing skin anesthesia for approximately 15 minutes. LAT, because it contains adrenaline that causes vasoconstriction, must not be placed on distal arteries (located on tip of nose, earlobes, penis, fingers, and toes). “Numby Stuff” is a commercially available product that uses a novel delivery system, iontophoresis, to deliver 2% lidocaine and epinephrine 1:100,000 approximately 10 mm into the skin. It takes approximately 10 minutes of use before dermal anesthesia is achieved. This device may be somewhat frightening to young children, who may not like feeling its mild current.8

The use of regional nerve blocks in anesthetized children to provide improved postoperative analgesia has expanded over the last 20 years.29,36 This technique, which involves the injection of long-acting bupivacaine or ropivacaine into nerves that innervate a designated area, can also be used to provide local...
anesthesia for surgical procedures such as circumcision or reduction of fractures.6,24

Long-acting anesthetics (e.g., bupivacaine, ropivacaine) can be given intraspinally (epidurally or intrathecally) in children. Administration of epidural medications (opioids, local anesthetics, clonidine) can effectively control pain in children, including preterm neonates.24,29 They are often given for postoperative pain control after specific procedures or in children with chronic pain who have not been helped by effective systemic therapy.29 The use of epidural analgesia in children requires special education and training on the part of the physicians and nurses. Careful calculation and administration of epidural medications and close postadministration observation are necessary to prevent serious complications. Nurses play a key role in setting the institutional standards for use of intraspinal analgesics in children.27,29

The following case illustrates the effective use of intraspinal analgesics in an adolescent.

**Jacob, a 15-Year-Old with Metastatic Cancer**

Jacob, a 15-year-old Orthodox Jewish boy with osteogenic sarcoma metastatic to the spinal nerve roots, was at home receiving hospice care. Because his pain was not well controlled, he was admitted on a Sunday for better pain control. An epidural catheter was placed for severe neuropathic pain, and Jacob became more comfortable. Jacob and his family were eager for him to be discharged home on Friday morning so that they could be together for the Sabbath, which begins at sundown every Friday. His doctors and nurses believed it would be better for him to stay a few more days while they titrated his analgesics. However, because of cultural issues in this family, they agreed to discharge Jacob home to the hospice nurses who were caring for him and his family. Jacob remained at home for the rest of his life, and his parents were grateful for their time with him.

Nonpharmacological Management

Nonpharmacological pain management interventions include psychological, physiatric, neurostimulatory, invasive, and integrative techniques. Components are frequently combined as part of a pediatric pain management plan; they are dependent on the comprehensive pain assessment of an individual child and are based on the presumed etiology of pain. In considering which nonpharmacological interventions might be beneficial, the nurse needs to look at several factors, including the child’s and family’s past experience with nondrug interventions. What has worked well and what has not? Are there religious or cultural issues or concerns that would make certain interventions not appropriate? Is the proposed intervention consistent with the developmental level of the child? What is the present cognitive status of the child? Has the stress and fatigue from a prolonged illness made it difficult for the child or family members to concentrate, follow directions, or learn new information? Also, the nurse should consider teaching potentially useful techniques before the skills are needed.37

Psychological interventions can include patient and family education, cognitive interventions, and behavioral techniques such as writing in a pain diary. Pain diaries may be especially useful in working with children who have recurrent or chronic pain, and their use has some value in pediatric pain research.38 Children who enjoy writing may benefit from a private place to express themselves. Young children who have not mastered the written word may find drawing about their pain and pain experiences helpful.

The value of cognitive techniques such as distraction and relaxation is well established in children. Across studies, distraction has been shown to reduce children’s behavioral distress during procedural pain, although it has a variable effect on pain intensity. Various distractors have been used for children’s pain management, including bubble-blowing, party blowers, puppetry, video games, and listening to music. The distractor is more likely to be effective if it is age-appropriate and complementary to the interests and preferences of the individual child.39 Nurses working with infants and toddlers, to the age of 2 years, may distract them with mobiles, rocking, stroking, or patting. Children from 2 to 4 years of age may find blowing bubbles, breathing, puppet play, or storytelling useful distractions. Four- to six-year-olds like these activities and may also like television shows and talking about favorite places. School-age children can be distracted with these activities and may also be receptive to humor, counting, or thumb squeezing. Progressive muscle relaxation exercise is used most effectively in older children and adolescents but can also be taught to children as young as 5 years of age. Guided imagery, which ideally incorporates all of a child’s senses, can help children “escape” to a safe favorite place unique to that child. Sometimes children like to imagine doing a favorite activity, such as swimming or skating.40

More research is needed regarding the efficacy and acceptability of the use of some complementary or integrative approaches (e.g., acupuncture) in children with pain before these modalities can be routinely recommended. Such data can potentially establish other credible choices for assisting children with pain as well.9

Nurses caring for children with pain have both collaborative and independent functions when implementing nonpharmacological interventions. Psychological interventions that a nurse should feel comfortable initiating include patient family education and cognitive techniques such as distraction, relaxation, positive self-statements, and pain diaries. An individual nurse might initiate the use of music as a distraction or distraction technique. Independent physiatric interventions can include movement and positioning and swaddling of neonates. Collaborative efforts may involve massage, vibration, or use of superficial heat or cold. (Protecting the child’s skin by placing the heat or cold source in commercially available animal wraps or using towels decorated with favorite characters may make the experience more enjoyable for young
children. The nurse needs to know which members of a child’s primary team are knowledgeable in the use of nonpharmacological techniques and which special consultants are available to help if needed.9 Child life specialists can be a resource for employing distraction and other psychological pain management techniques in children.9 Cognitive techniques such as biofeedback and hypnosis, although potentially useful for children with chronic pain, require the use of trained instructors for initiation.41

The resources available to the nurse (including time available to initiate a particular intervention, education in a particular technique, availability of patient/family educational materials, and availability and affordability of particular devices) play a role in what techniques are initiated with an individual child.40 The Institute of Medicine noted that the teaching of cognitive behavioral techniques, despite their demonstrated effectiveness, is not done in as rigorous or consistent a way as is observed for other clinical modalities.9 More detailed information regarding the use of nonpharmacological pain relief methods with children can be found in a variety of sources for those wishing to expand their practice.5,6,41

Procedural Pain Management

Procedural pain is a widespread experience for most children interacting with the health care system. Nurses who know how to successfully address procedural pain, using both pharmacological and nonpharmacological techniques, can help a very large number of children. Procedural pain is the one area in the pain literature that is much better developed for children than for adults, who may also experience this problem. The goals of successful procedural pain management include minimizing pain, maximizing patient cooperation, and minimizing risk to the patient.42

Anticipation is the key word. Having procedures performed by technically competent individuals can reduce both risk of pain and risk of harm. The medical personnel involved must be knowledgeable in both pharmacological and nonpharmacological pain management appropriate to the child and the situation. Both children and parents need appropriate information regarding what will happen and how they can decrease stress.24

How pain is avoided or managed the first time a child undergoes a particular procedure influences how the child anticipates and copes with subsequent procedures. It is recommended that pain and anxiety be maximally treated the very first time a child undergoes a procedure.43 Depending on the procedure and the individual child, this can be as simple as providing information and topical analgesics or vapo-coolant immediately before needle punctures or as complex as administering conscious sedation with the combination of an opioid analgesic and a benzodiazepine. A recent review of the effectiveness of conscious sedation for anxiety, pain, and procedural complications in young children suggests that its use should be considered and advocated if a child is experiencing a heightened stress reaction.44 It is important to bear in mind that the use of anxiolytics or sedatives alone does not provide analgesia but does render a child unable to communicate distress.24

It is useful to discuss coping strategies with the child and parents, if possible, long before the medical procedure. This enables them to mentally rehearse ways in which they can cope with the situation when it occurs.39 Review of the literature by Christensen and Fatchett45 revealed that distraction, relaxation, and imagery are effective for children in decreasing anxiety and pain associated with painful procedures. Therapeutic play and orientation to the room and equipment may help to promote patient cooperation. Risk can be minimized by having all equipment, supplies, and staff ready and available for both routine and emergency care.

Other things the nurse can do to facilitate comfort for children during stressful procedures include inviting the caregiver to be present and attending to environmental factors. This includes using a treatment room whenever possible; creating a pleasant environment; minimizing noxious noises, sounds, and sights; and maintaining a calm, positive manner. Attending to these details can not only increase the comfort of the parents and the child but also that of the health care personnel involved.46 Finally, during and after the procedure, the nurse needs to provide ongoing assessment of pain and anxiety and work to collaborate and modify the treatment plan if suboptimal control of either occurs.

Where Improvement Is Needed

All children are vulnerable to inadequate pain assessment and management. Those most vulnerable include the preverbal child, the cognitively or neurologically impaired child, immigrant children, and children without homes or consistent caregivers. System issues that interact with the barriers discussed earlier also need to be addressed (see Table 55–3).2 For example, children cared for in pediatric tertiary care centers may find that health care professionals in their home environment lack up-to-date information about pain assessment and comprehensive pain control in children.9

Long-term follow-up and outcome expectations and monitoring are important in preventing, anticipating, and alleviating pain in the pediatric population. Implementing a successful pediatric pain management program is more complicated than just selecting a pain assessment tool and requires a commitment of resources.26 To follow up in a systematic way and promote the timely and adequate use of appropriate medications and behavioral interventions for children, initiatives have been started that work to develop and implement evidence-based pediatric pain assessment and management protocols.5,47,48 Disease-specific guidelines have been developed for children with SCD18 and JCA,20 and a position paper has been published by the Association of Pediatric Oncology Nurses for pain management of the child with cancer at the end of life.49 It is hoped that pain will receive this kind of attention in other pediatric populations.
To start to improve the process of pain management, it is necessary to collect information about the present process, to develop an awareness of all the various factors that may either promote or deter achievement of the desired outcome. The literature reveals several efforts to collect baseline information about pain management and areas for improvement.\(^5\)\(^6\)\(^7\) One area to consider is that of pain medication errors. Sources of errors in pediatric medication administration include dilution errors, milligram-microgram errors, decimal point errors, and confusion between a total daily dose and a fractional dose.\(^7\)\(^8\) Through application of the quality improvement process, nurses can play an important role in improving pain control for both the individual children they care for and other children that they may not be directly involved with.

**Summary**

Despite the significant increase in knowledge about assessment and management of pain in infants and children, too many suffering children do not receive proper treatment. In today’s age of “powerful, invasive medicine, we can save more lives, but any wrong choice turns medicine into torture, inflicting avoidable sufferings on patients” (p. 2).\(^9\) To prevent suffering for children and their families, nurses and other health care professionals must apply the most up-to-date techniques of pain assessment and management to all children they care for, especially from the time a child receives a diagnosis of a potentially life-threatening illness through his or her survival or death. By application of an integrated treatment plan that is based on the developmental level of the individual child, involves his or her family, and uses both pharmacological and nonpharmacological interventions, optimal pain control is possible.\(^2\)

The Experience of the Nurse in End-of-Life Care in the 21st Century

Once you do hospice nursing you are never the same—love it or hate it, it brings mortality straight into your face.—A hospice nurse

Key Points

- Hospice palliative care nursing can be both stressful and very rewarding.
- Caregivers may see their work as a job, a career, or a vocation, and their perceptions of stressors and ability to cope may vary accordingly.
- Hospice palliative care nursing is whole-person care in that the whole person of the patient and caregiver must be considered in the process of truly caring.
- To care for others effectively, we must care for ourselves.

The discipline of hospice palliative care nursing began more than 30 years ago. The author has been involved in the field as a researcher, educator, and practicing clinician since before its early days and has written what might be seen as snapshots of stress and coping in hospice palliative care at various points over the past three decades.1-7 This chapter focuses on the experience of hospice palliative care nursing at the beginning of the 21st century.

Method

The literature from the first 4 years of the new century was reviewed. Early in 2004, hospice palliative care nurses were interviewed in two settings: an inpatient palliative care unit in a large teaching hospital in Canada (N = 6) and a free-standing hospice with an inpatient unit, a hospice home care team, a palliative care home care team, and satellite units on the west coast in the United States (N = 16). The nurses were asked to comment on the stressors and satisfactions of hospice palliative care; how their stress was manifested; what, if any, role spirituality played in their personal lives and clinical practice; and how they coped in their role in hospice palliative care. In addition, nurses on the Canadian Hospice/Palliative Care Nurses Listserv were invited to respond and to describe their experience of palliative care, its stressors, and coping mechanisms they had found to be effective. Between late 2003 and early 2004, 23 nurses and one music therapist responded. Some nurses gave responses from their units or their community practices, as well as personal experiences. Colleagues from abroad wrote, telling some of their stories, and discussions were held with colleagues at the International Workgroup on Death, Dying and Bereavement Meeting in March 2004. To all of these people who shared their experiences and wisdom, the author is deeply grateful. Although not every respondent can be quoted, each interview has contributed to this chapter.
To ground this chapter in the reality of clinical practice and to show the process of the career of practitioners in the field, the chapter opens with excerpts from a letter received in response to the author’s request to members of the Hospice/Palliative Care Listserv.

Hello Mary,

... It is now 23 years since I first heard you present at a conference (in Calgary). I have been drawn to this work since that life-changing conference, and have been involved directly and indirectly with hospice palliative nursing for over 20 years. But more importantly, I know many nurses and health professionals who have remained active and committed to this work at a frontline level. This is an amazing feat and, to me, flies in the face of prevailing perspectives of death saturation, accumulated losses, and burnout. This phenomenon truly warrants further investigation, discussion, and research.

I was delighted to see a qualitative study by Webster and Kristjanson’s last year that proposed that hospice palliative care has exhilarating and vitalizing components. I think their research extends our understanding on the nature of palliative practice. Although I have not seen discussion yet in the literature, I suspect that one linkage between the notion of vitalization and hospice palliative nursing is located within nurses’ opportunity to bear witness as their dying patients engage in their search for meaning. As Davies and Oberle write, “finding meaning is strength-giving.” Indeed it is. I contend it is strength-giving not only for the patient/person who is living with dying, but for the nurse who journeys with that individual and family. Work-life conditions drove me away from direct care at a hospice, in search of an educator role, and the right to go to bed at night, to preserve my health and sense of well-being. To this day, I mourn the loss of my capacity to directly provide nursing care to dying persons and their family.

As you prepare to update the important chapter on stresses related to hospice palliative nursing, I hope that you can find a way to represent and articulate the other perspective related to the impact of this work: its capacity to inspire and inspirit the palliative care nurse. —Deanna Hutchings, RN, MN; Victoria, BC

Frameworks for Viewing Hospice Palliative Care

In their powerful book, Crossing Over: Narratives of Palliative Care, which describes the experience of palliative care in two settings in the United States and Canada, Barnard and colleagues stated, “Palliative care is whole-person care not only in the sense that the whole person of the patient (body, mind, spirit) is the object of care, but also in that the whole person of the caregiver is involved. Palliative care is, par excellence, care that is given through the medium of a human relationship” (p. 5). These authors documented the experiences of patients, families, and caregivers during some of their finest and not so fine moments. The reader comes to understand the humanity of all involved. Figure 56–1 reminds us that the caregiver as much as the patient will one day also face personal death.

A more recent study of nurses in a European academic palliative care setting (n = 14) was undertaken to gain insight into the fact that many nurses were leaving feeling frustrated by the far-reaching medical orientation on the ward and unable to provide the care they wanted to give. These nurses were not neophytes. They were typically oncology nurses, 35 to 53 years of age, who had been working on this unit from 6 months to more than 4 years. They raised questions about the benefits and burdens of the medical treatment with which they collaborated. This study challenges whether the assumptions of Barnard are completely generalizable at this point in time and may shed light on some of the conflicts hospice palliative care nurses are experiencing in the early years of the 21st century.

In order to understand the process that hospice palliative care nurses might experience in adapting to their role, the work of Georges and associates is compared with that of Bernice Catherine Harper. Dr. Harper is a social worker whose initial work involved supervising other social workers at City of Hope Hospital in California. Her model proposes that “learning to be comfortable in working with the dying patient and his family must be preceded by a growth and developmental process or sequence including cycles of productive change, observable behavior, and feeling” (p. 124). The stages of her model are described in depth in Chapter 2 (see Figure 2–1).

Striving to Adopt a Well-Organized and Purposeful Approach versus Striving to Increase the Well-being of the Patient

The study by Georges and associates showed a different pattern of practice from that described by Harper and by Barnard and coworkers. Georges’ group observed that the concept of palliative care demands that relationships with dying patients and their family members must be grounded in a real encounter and shared mutual understanding, and not in self-conscious use of

Figure 56–1. The very thing that we fear, we carry within us right now—our corpse. (Milarepa). Source: Mary Pocock, http://www.keylight.org (accessed February 28, 2005).
psychosocial skills and techniques. Harper states that health professionals must learn to cope with the anxieties which arise from such interpersonal experiences, coming to grips with their own feelings about mortality—both theirs and the patient’s.12 Palliative care is defined as a moral practice, based on hope and acceptance, that creates freedom and space for individual patients.14

That palliative care goes beyond the management of physical symptoms is well known but can be illustrated by the fact that 57% of 814 new referrals to the McMillan Nurses in the United Kingdom were for emotional support.15

Georges and colleagues11 found that on the unit they studied, which was having trouble retaining nurses, two methods of practice described the nurses’ actual activity. The first and more prominent method was “striving to adopt a well-organized and purposeful approach as a nurse on an academic ward” (n = 12); the second was “striving to increase the well-being of the patient” (n = 2).

**Striving to Adopt a Well-Organized and Purposeful Approach in an Academic Setting**

Several of the nurses adopted an academic attitude, underpinning their nursing practices with a scientific and professional rationale. They felt that it was important to use a “scientific” classification system of nursing diagnosis, to formulate nursing interventions in relation to the diagnosis, and to work within the limits set by the policy of the ward and the hospital. These nurses were very concerned with appropriate bed utilization and attempted to make discharge arrangements at an early stage in order to avoid unnecessary occupation of beds. The authors noted that, for these nurses, carrying out the nursing process in a professional manner was more important than investing in their relationships with patients.

**Developing a Professional Attitude.** A professional attitude refers to the rational approach of nurses, which is principally directed to gaining information about patients’ symptoms and gaining insight into their problems. These nurses had a more detached attitude and tended to focus on identified tasks and problems. For example, when giving information to patients, nurses may pay much attention to clarity and completeness while failing to consider the emotional impact of the message.

**Striving to Remain Objective.** These nurses described patients’ health problems in a formal language. They avoided speaking about problems that could not be labeled well, because they were not sure members of the multidisciplinary team would understand them. They argued that being objective was more in accordance with current professional developments in the field of nursing. They used diagnostic instruments to establish their observations. This allowed them to feel more comfortable speaking with physicians, to feel they were seen as being more trustworthy, and hence to be involved in the decision-making process. These nurses consciously strived to avoid allowing their feelings to have an impact on the way they responded to situations.

**Being Task Oriented.** These nurses were mostly committed to improving the situation of patients by solving or reducing their problems. They found it important to see that their interventions actually did improve the situation. If it was not possible to find a solution for patients’ problems (e.g., to achieve sufficient symptom control, especially pain) nurses felt powerless and felt that they had not been able to achieve something meaningful for their patients.

**Avoiding Emotional Stress.** Coping with the emotional aspects of palliative care was a leading theme in the interviews with these nurses. The stress they experienced seemed to be related mainly to their appraisal of, and approach to, palliative care. Some said that the gravity of caring for dying patients would inevitably lead to burnout, so they did not plan to work too long in palliative care. These nurses tended to distance themselves from patients by focusing on tasks and the treatment of symptoms. Some nurses explained that their experience had taught them to remain more professional and detached, while others decided consciously not to invest too much in their relationship with patients because it would be too demanding. This way of coping is not only found in Europe. Kelly and coworkers16 wrote of dealing with death on the bone marrow transplantation (BMT) unit. They found that nurses often deny the difficulty of BMT, their emotional attachment to the patient, and the quality of the patient’s life. They suggested that denial of emotion, if not appropriately reflected upon as a necessary strategy for dealing with very uncomfortable events, avoids a context in which understanding and ways of coping may be developed.

**Embracing a Practitioner-Focused Perspective.** It seems difficult for nurses to distance themselves from their own beliefs and to learn to be available to discern the perspective of patients and the meaning of the situation for them. Working in accordance with rules, these nurses emphasized the need to respect important rules of the ward. For example, if patients mentioned that they were considering euthanasia, some nurses explained that they first had to follow the procedures of the organization and then went on to explain them to the patient. “These nurses, by being mainly directed to using a rational and ‘scientific’ approach to their tasks, could fail to meet the real needs of patients and to pay sufficient attention to the development of a compassionate attitude. This perception, which was very much present on the ward, is mainly characterized by a distant approach towards patients and a well-developed self-awareness to work on one’s own development as a professional.”11

**Striving to Increase the Well-being of the Patient**

Nurses who practiced under the second model, of striving to increase the well-being of the patient, felt that it was important to use their individual capabilities, such as being sensitive to patients’ concerns, and they adapted their approach to individual patients. They found that, when fully aware of the needs of patients, it was not difficult to explain them to other caregivers.
Care appeared to be a central concern for these nurses and a main source of satisfaction. They were aware that, thanks to their caring attitude, they could mean something to patients, even if only for a short time, and they felt this to be rewarding.

Adopting a Humble Attitude. In order to act in accordance with the needs of patients, these nurses tried to put their own considerations aside and to find a way to cope with their own emotions. They strove to adopt an unobtrusive approach and to show their availability to patients without forcing anything, even without expecting patients to answer their “invitation.”

Giving Attention to Patients and Their Experiences. The approach of some nurses seemed to be shaped by their sensitivity to the feelings of patients. Being aware of patients’ experiences is related to individual efforts to discover and understand what patients experience and why they react as they do. To be conscious of patients’ experiences requires being really present. Some nurses, for example, were concerned that giving inadequate or incomplete information to patients could badly affect the direction of their decisions about further treatment. By their sensitivity to the experiences of patients, they became more connected with them and tried to really help them, even if they had to “break the rules.”

Being Available. Being available, truly present, appeared to be a major virtue of nurses that allowed them to perceive the troubles and needs of a patient. They spoke about being sensitive to unspoken messages and about trusting their intuition. Being receptive to what is going on helped them see how they could contribute to the well-being of patients.

Valuing a Caring Attitude. The meaning nurses assigned to their work was based mainly on their experience as nurses and on their daily encounters with patient care. They developed a caring attitude based on authentic relationships with patients.

Remaining Attentive and Thoughtful. In order to find solutions to the problems they were confronted with, these nurses used self-reflection, striving to adopt a patient-centered attitude and to improve their caring attitude. They were also attentive to the context of their work, particularly to what should be changed so as to make it easier to express a caring perspective.

Trying to Accept and Cope with Emotional Strain. Nurses recognized that by caring for patients whose life was limited they were exposed to painful moments. However, they tried to accept emotionally difficult situations as a part of their own reality and did not attempt to avoid them. They strove to remain “authentic” and to stay close to patients even if they could not alleviate their problems.

Harper’s Model of Cumulative Loss and the Caregiver

Bernice Harper’s\(^{12}\) work has been extensively described in Chapter 2. According to her model, there are six stages of adaptation experienced by the nurse caring for dying patients. These stages include intellectualization, emotional survival, depression, emotional arrival, deep compassion, and the Doer. To view Harper’s model, called the “Line of Comfort-ability,” the reader is referred to Figure 2–1.

Reflections on a Comparison of the Two Models

A comparison of Harper’s work\(^{12}\) with that of Georges’ group\(^{11}\) shows that, although Harper’s model is very useful to describe the career path of some nurses in palliative care, there may be others who do not progress in the manner that Harper describes. From her perspective, these nurses may never have evolved beyond the first stage of comfort-ability. They are still involved in an intellectual approach to their role and are defending against allowing emotions to intrude. However, the nurses in the category striving to increase the well-being of the patient could be seen to be in Harper’s stage IV or higher, in which they have “the control to practice the art of one’s science” (p. 71).

Part of the reason for the split between the two approaches to nursing may be the bureaucratization of hospice palliative care. As Byock\(^{17}\) noted, Max Weber, the renowned German sociologist, observed that, although social movements evolve to meet the needs of the time, they continue only through the process of bureaucratization. “Routinization is part and parcel of a social movement’s success; with it comes stability, confidence and bureaucracy.”\(^{18}\) Some of the issues being confronted by the nurses in the Georges study\(^{11}\) can be seen as related to the bureaucratization and standardization of palliative care. Both Doyle\(^{19}\) and Kearney\(^{20}\) warned earlier that palliative care specialists needed to avoid becoming merely symptomatologists. The field needed to recognize that

We are, in the presence of death, working toward health—that balance of body, mind and spirit that is so much more than freedom from disease. For that reason I believe we have no choice but to be alert to and responsive to human spiritual needs.\(^{19}\) [It is] as though the dragon (that is the patient’s distress) also guards a treasure—something essential for that particular individual’s healing at that moment in time. It is suggested that if we in palliative medicine fail to accept this view, a view which allows that there may also be a potential in the suffering of the dying process, if we sell out completely to the literalism of the medical model with its view that such suffering is only a problem, we will be in danger of following a pattern which could lead to our becoming ‘symptomatologists’, within just another specialty.\(^{20}\)

An alternative explanation for nurses’ maintaining distance from patients is that the nurses previously practiced a more patient-centered approach to nursing but stopped doing so because of their emotional reactions, for which they may not have had appropriate help and mentoring.

A nurse with many years of experience felt that she used to get overinvolved with her patients, but now she guards against that happening. She became very involved emotionally with a woman dying of amyotrophic lateral sclerosis:
She asked me to tell her when it was time to let go—when she got real close. One day she was not able to move. She could only blink one eye. She was lying in semi-Fowler’s position, keening in her throat. I didn’t know if her problems with shortness of breath were because of fear. I got her to the inpatient hospice unit. The next day she was still doing it, so I knew she wasn’t there yet. I came out of her room and talked with the doctor and nurse. They planned to increase her morphine. I don’t know what was on my face, but the chaplain asked, “Are you OK?” I said, “No.” That was the first time it ever hit me like that. The next day she was better. Her breathing was quieter and gentler. Every day I’d go and say good-bye. That was my way of saying that she could let go. After several days she was still there—she had will. I asked the family if they had told her it was OK to go. I guessed that I would have to say it. I bent over and whispered in her ears, “It’s OK to go now.” She died that night. I had some feeling that maybe I hadn’t done it soon enough and I had guilt. I don’t want to be God, tell them it’s OK to die. I didn’t think that was my place, but I did it occasionally.

Now I’ve changed my job in order to still be able to remain in hospice. I didn’t want management, but I had to back off because of several people I became very involved with. I needed to take a breather. I’m breathing here in extended care, with team support. There was an opening on nights. I took it tentatively. It’s working for me. I don’t have obligations at home, and I enjoy having some time off during weekdays. I’m not trying to escape from the intensity. I still go through intense moments. The intensity is good. . . . Now I’ve switched to nights. It provides a level of involvement that I can deal with that doesn’t drain me so much.

Today some nurses may be straddling the fence between a deep involvement in patient care and feeling challenged by bureaucratic issues; others may be carrying on their practice in the manner that Harper describes, whereas others may be practicing a type of nursing that might be more common to that seen in traditional medical settings. The nurse in the above anecdote had clearly evolved through some of Harper’s ways in which stress may be expressed.

Meier and colleagues21 described what might happen in physicians, and these comments hold true for nurses as well (p. 3007):

Seriously ill persons are emotionally vulnerable during the typically protracted course of an illness. Physicians respond to such patients’ needs and emotions with emotions of their own, which may reflect a need to rescue the patient, a sense of failure or frustration when the patient’s illness progresses, feelings of powerlessness against illness and its associated losses, grief, fear of becoming ill oneself, or a desire to separate from and avoid patients to escape these feelings. These emotions can affect both the quality of medical care and the physician’s own sense of well-being, since unexamined emotions may also lead to physician distress, disengagement, burnout, and poor judgment.

These authors provided a model of reflective practice for physicians to use to increase their awareness and improve their clinical practice.

This next section of this chapter discusses some of the stressors currently experienced in hospice palliative care and the ways in which stress may be expressed.

Stressors in Palliative Care

This letter received from one of the nurses on the Canadian Hospice/Palliative Care Listserv gives a perspective of palliative care in a somewhat rural area of Canada and summarizes much of the stress and satisfaction received by hospice palliative care nurses.

Well, as I was traveling around over the past two weeks throughout [the area I cover], I asked the nurses what they thought the stresses were in working in palliative care. . . . The community nurses—probably the most unsatisfied of all nurses, due to the awful working conditions [listed the following]:

- No full time positions, therefore no security
- Limited number of visits [they are allowed to make] . . . even if they think there are more needs
- Feeling of lack of support by a team; difficult to get together to debrief; isolated practitioners out on the road; no 24-hour care available; difficulty in being able to reach a physician when needed; lack of family doctors, so patients have to go to the hospital
- Emotional strain and need for more support
- Need for more pain clinics or access to pain specialists
- Dying children
- Families treating them either really nicely or really badly (One nurse told that she was not allowed to heat up her tea in the microwave, sit too close to the patient, etc.)
• Funding issues
• Communication between hospital and community
• Late referrals from city hospitals when patients come back to community means little time to establish relationships and crisis pain management
• Difficulty keeping the family doctor involved during treatment, so that he or she will be up-to-date when the patient is at the end of life

However much as it sounds like their work is terrible, these nurses love their patients. It is just that they have to be so incredibly flexible, astute in their perceptions of the situations and understanding of the difference in families’ reactions. This story just recently happened and shows the incredible courage and fortitude of nurses:

A patient had been dying slowly in the hospice suite in the community, but the goal was to go to hospital at the end, because the hospice is not staffed for end-of-life care yet. However, when the time came, the hospital was full and couldn’t take her. The hospice nurse found the lady in the emergency department and, when it became inevitable that she couldn’t be admitted, told the paramedics to take the lady back to the hospice suite. She got on the phone, notified the physician, called the community agency for any help they could give, rallied her own nurses and volunteers (this meant using up every last cent in her budget), and made the patient comfortable in the lovely environment of the hospice. The community nurse pulled out all the stops and got as much nursing help as she could also. The patient lived for several days, much to the amazement of the staff. One thing that she had requested before she died was to renew her wedding vows, and, sure enough, the staff got that organized very quickly and she died 12 hours later.

What a story of amazing flexibility and drive, all to make the end of life the best they all could for this woman.

Generally speaking, even though these nurses carry many stresses in their palliative care work, there are many dedicated ones who wouldn’t work in any other field. Hats off to them, but we as managers and advocates must speak up for them to make their work life better.

A Model for Understanding Occupational Stress

Maslach and associates\(^2\) reviewed the research on burnout over the past three decades. Previous research had focused on the Person-Environment Fit model.\(^2\) More recent research has focused on the degree of match or mismatch between the person and six domains of the job environment. The greater the gap or mismatch between the person and the environment, the greater the likelihood of burnout. The greater the match or fit, the greater the likelihood of engagement with work. Mismatches arise when the process of establishing a psychological contract leaves critical issues unresolved or when the working relationship changes to something that the person finds unacceptable. Mismatches lead to burnout. Six areas of work life come together in a framework that encompasses the major organizational antecedents of burnout.

Workload—Excessive workload exhausts the individual to the extent that recovery becomes impossible. Emotional work is especially draining if the job requires people to display emotions inconsistent with their feelings. Workload relates to the exhaustion component of burnout.

Control—Control is related to inefficacy or reduced personal accomplishment. Mismatches often indicate that individuals have insufficient control over the resources necessary to do their work or insufficient authority to pursue the work in what they believe is the most effective manner.

Reward—Lack of reward may be financial if one does not receive a salary or benefits commensurate with one’s achievements, or social, if one’s hard work is ignored and not appreciated by others. The lack of intrinsic rewards (e.g., doing something of importance and doing it well) can also be a critical part of this mismatch.

Community—This mismatch arises when people lose a sense of personal connection with others in the workplace. Social support from people with whom one shares praise, comfort, happiness, and humor affirms membership in a group with a shared sense of values.

Fairness—This mismatch arises when there is not perceived fairness in the workplace. Fairness communicates respect and confirms people’s self-worth. Mutual respect among people is central to a shared sense of community.

Values—Individuals may feel constrained by their job to do something that is unethical and not in accord with their own values. Alternatively, there may be a mismatch between their personal career goals and the values of the organization. People can also be caught in conflicting values of the organization, as when there is a discrepancy between a lofty mission statement and actual practice, or when the values are in conflict (e.g., high-quality service and cost containment do not always coexist).

Burnout arises from chronic mismatches between people and their work settings in some or all of these areas. Preliminary evidence suggests that the area of values may play a central mediating role for the other areas. Alternatively, individuals may vary in the extent to which each of the six areas is important to them. Some people may place a higher weight on rewards than on values, or some may be prepared to tolerate a mismatch regarding workload if they receive praise and good pay and have good relationships with colleagues.

The recent research on hospice palliative care nursing is now reviewed within this framework.

Workload

Hospice nurses initially prided themselves on having the time to spend with patients that was conducive to the best patient care. Current issues with managed care, the nursing shortage,
and fiscal restraint have changed this situation in many settings.\textsuperscript{24} A study in the Netherlands found that direct patient-care activities had an impact on stress through a heavy workload of complex care, a shortage of staff, and an experienced lack of competence.\textsuperscript{25} Papadatou and colleagues\textsuperscript{26} found that nurses working with critically ill and dying children in Hong Kong and Greece felt unable to provide quality care because of the shortage in nursing personnel. This added to their stress. However, in a study of hospice nurses in the United Kingdom, Payne\textsuperscript{27} found that, despite that fact that workload was a frequently reported stressor, it was not related to burnout, suggesting that some stress may be necessary for optimal functioning.

Several of the nurses interviewed for this chapter commented on the issue of workload. A selection of comments follows.

A Canadian nurse working in a rural setting stated,

\textit{Stress. . . . . that’s the word of the year, I think. It seems that while the workload is increasing, funds continue to decrease. We are all trying to do more with less . . . and it’s beginning to show.}

A nurse in a large palliative care program commented,

\textit{I’m stressed out by being overloaded with 14 to 15 patients. There is a high acuity level with each patient. We don’t have enough time to deal with each patient. I try not to carry my frustration into the next person. Too much work, not enough time. The workload is unmanageable. I’ve worked for 10 years in hospice. We have to keep doing more, faster with less. There is a push for productivity, what your case load is, how fast you can work, how little overtime you can bill for.}

A palliative care nurse who had worked in many settings commented on the role strain that she had felt in a previous position:

\textit{It would be 3:00 A.M. I’d be driving in west Texas avoiding the cows in the road. There were no streetlights. I would be winging it and praying for good directions. I’d be going to the drug store meeting with the pharmacist in the middle of the night. Hopefully I’d have a good doctor who would cover me. I’d hope and pray that I wouldn’t have to go back and pronounce the person soon after I left. I’m a single Mom. I’d bring the kids when I was on call. I’d pile in pillows and the dog and try to make it fun. We’d go to a restaurant or a park. The kids would ask, “Mom, are you on call? Are we going on an ’excavation’?”}

**Control**

Current research suggests that restructuring of high-demand, low-control jobs may enhance productivity and reduce disability costs.\textsuperscript{28} Recent practices in hospice led by fiscal constraints have raised increasing concern. Nurses are sometimes expected to perform procedures in the community for which they have not been prepared and for which no supervision is provided. When people are expected to assume responsibility with inadequate training, they have difficulty functioning.

Nurses report being in situations, both in the hospital and in the community, in which they feel responsible for alleviating the pain of a palliative care patient yet do not have a physician willing to order the medication they feel is sufficient to control pain.

I’m the admitting nurse. I have so many hours to get a patient on the service. I can’t predict if the doctor will call back. He may not call back until the next day. It can happen that I am at X Hospital. The patient is going home. I call his doctor and tell him that the patient is short of breath and there isn’t an order for Ativan. The doctor may not call back until tomorrow. We could use our hospice doctor, but I don’t want to make the referring doctor angry.

In addition, with the earlier discharge of sicker patients, nurses with limited experience may be expected to care for seriously ill palliative care patients in their home, without access to physicians skilled in effective palliative care and symptom management.\textsuperscript{29} Dr. Neil MacDonald\textsuperscript{30} testified before a Senate Subcommittee on End-of-Life Care in Canada that the opinion of Quebec oncologists and palliative care physicians in one study was that the big problem in managing cancer pain was the reluctance on the part of physicians to use opioids and the misunderstanding of patients about the use of pain medications.

An American nurse said that when she reported that a dying patient was in severe pain and she felt that he needed to have his medication increased, the physician asked who he was treating—the patient or the nurse?

Issues of control can also be related to physical safety. Nurses reported feeling unsafe when they were making visits to deserted country homes in the middle of snowstorms without access to cell phones or other ways of communicating if there is trouble; visiting in unsafe areas of the community, where the nurses do not feel safe during the day, and particularly at night; and visiting in homes where the family dynamics are such that nurses do not feel physically safe. If there are no organizational policies about how to handle these situations, staff can feel quite stressed.\textsuperscript{24}

Nurses may also feel out of control if they begin get emotionally involved with patients and families without sufficient supervision and support. Barnard and coworkers\textsuperscript{31} noted the need to give full weight to both the promise and the fear of intimacy in palliative care and referred to palliative care as challenging caregivers to leap into the confrontation with the forces of chaos and disintegration (p. 26):

\textit{We live in the tension between the promise of intimacy and the fear of our own undoing. Surprised by intimacy, we are exhilarated and lifted beyond ourselves, as if we have not only made contact with another person...}
but also with another dimension of living. At the same time we are brought face to face with forces of chaos and destructiveness, internal as well as external, and we fear that we ourselves shall be destroyed.

These feelings can lead caregivers to feel out of control and to experience significant role strain.

Nurses also feel out of control because of the timing of patient referrals:

Patients are referred later and sicker. They are more acute. You don't have the time that you used to have. Ten years ago we had patients for a couple of months on average. Now it is just weeks. The doctors don't refer until later because there is a fear of referring too soon with reimbursement. There are more treatment modalities. Patient's families want them to try more. There is less time for me to do what I need to do, which is (1) palliate symptoms, (2) prepare people for impending death, (3) be a supportive presence so they aren't so afraid, and (4) establish a trusting rapport.

An inpatient male nurse commented:

Patients come when you can't control it, they poop when you can't control it, want ice when you can’t control it. There are other jobs with more control. I came into nursing kicking and screaming to do hospice nursing. I spent a lot of time looking for something fulfilling to do with my life. I thought, “If there is a purpose to life, then I should be able to find it.” I came to terms with being a man in nursing. I love my job. I’m here on my day off. There is so much work. Someone poops when I have to do paperwork.

Nurses can also feel out of control if they believe that they do not have the necessary education to handle problems with patients and families. White and colleagues asked respondents to rank-order 12 topics that comprise end-of-life care competency that they wish they had learned in nursing school. Almost two thirds of the respondents ranked one of three competencies highest: how to talk to patients and families about dying (30%), pain control techniques (28%), and comfort care nursing interventions (9%).

Older nurses (born before 1946) were 40% more likely than were nurses born after 1946 to rank how to talk to patients and families about the dying process as number 1. “Baby boomers” nurses (born between 1946 and 1964) were 28% more likely than were the other age groups to rank how to talk to patients and families about the dying process as number 1, followed by “generation X” nurses (born after 1964) at 27%. This difference by age group might be related to the times when these nurses were educated and the prevailing attitudes about nurses’ roles in communicating with patients and families about dying. In addition, longer life spans and demands for end-of-life care are greater now than when older nurses received their education. One might have hoped that ongoing education and maturing would have helped the older nurses to be more comfortable dealing with these issues, but that did not seem to be the case.

Reward

Funding issues were a problem for many programs. Participants in the Australian study reported that economic pressures resulted in less staff support, competition between services for funding, inadequate funding to provide services in areas of need, lack of support for psychosocial needs including bereavement care, and experienced staff’s leaving palliative care. Nurses in a Canadian study reported difficulty with resource allocation issues, but the majority of their concerns were related to their inability to provide quality care because of financial constraints and staffing cutbacks.

An American nurse noted some of the difficulties with the financial reward of hospice palliative care nursing:

The money isn’t very good in a not-for-profit hospice, but I can cope with the pay. I could make more, though, in a for-profit hospice.

Community

Team communication problems have been a significant part of hospice palliative care and, to a lesser extent, the field of oncology since the early days of these specialties. The research on this subject has been reviewed elsewhere. Team issues have been documented in numerous studies and across many cultures.

Lack of cooperation and discipline occurs when teams have coordination without cooperation. If team members are ordered about without consultation or participation, they will not give their best effort and will fail.

Studying hospice nurses in the United Kingdom, Payne found that dealing with death and dying, inadequate preparation, and workload were slightly more problematic than were conflict with doctors, conflict with other nurses, lack of support, and uncertainty concerning treatment. However, in that study conflict with staff contributed to both the emotional exhaustion and depersonalization subscales of the Maslach Burnout Inventory.

Community can also refer to the community in which caregivers live. Palliative care workers in rural Australia spoke of the difficulty involved in being expected to work beyond normal working hours and of the lack of anonymity in a small rural community.

Fairness

Rivalries between hospice and other settings of care and between different hospice programs have long been an issue. Rivalries are encountered as programs try to determine with which agencies, if any, they will have preferred partner arrangements. Other settings have developed palliative care programs in an apparent move to avoid referral to hospice and to gain access to
funding that might be made available for dying persons. In addition, there are financial barriers, including reimbursement systems that provide only for the options of cure or certain death.

Whedon, an oncology nurse whose practice changed to pain and symptom management, observed (p. 27),

Patients without a care provider; unwilling to forego beneficial palliative chemotherapy, radiation, or surgery; or with a prognosis that was not absolutely certain to be 6 months or less, were caught in the middle. This part of the path felt treacherous; we had no trail markers, no compass, and darkness was about to fall.

Values

Webster and Kristjanson did a small qualitative study of caregivers in various professions working in palliative care. They spoke of the importance of being allowed to bring personal values to the workplace and of being encouraged in their personal growth.

Oberle and Hughes did a qualitative study of 7 doctors and 14 nurses working in acute care adult medical-surgical areas, including intensive care. The respondents were asked to describe ethical problems that they frequently encountered in their clinical practice. All participants experienced ethical problems related to decision-making at the end of life. The core problem for both doctors and nurses was witnessing suffering, which engendered a moral obligation to reduce that suffering. Uncertainty about the best course of action for the patient and family was a source of moral distress. Competing values, hierarchical processes, scarce resources, and communication emerged as common themes. The key difference between the groups was that doctors are responsible for making decisions and nurses must live with those decisions.

Nurses experienced moral distress in these uncertain situations when they believed that the wrong course of action was being followed and they were contributing to the patient’s misery. Nurses tended to judge the doctors’ actions as a function of whether they had made the right decision and written the right order. Nurses often had clear ideas about what was acceptable and what was not, reflecting a degree of certainty not evident in the doctors’ responses. Distress arose for nurses when they perceived that the patient’s suffering was intensified because doctors just could not or would not write the “appropriate” orders. However, paradoxical thinking was evident in many of the nurses’ responses. Whereas they expressed concern that the doctor had not made the “right” decision, they also recognized that the decisions were difficult and that outcomes were, indeed, uncertain.

Competing values operated in these situations. Decisions about care and treatment at the end of life are intrinsically value laden, and recognition of this fact raised concerns for all participants. Questions arose about whose values should carry the most moral weight in any given situation and whose values had, or should have had, the most impact on decisions taken. This was particularly problematic if the patient was unable to speak for himself or herself. The value embraced by all participants was the good of the patient. In the absence of a patient voice, patient autonomy was not a realistic goal, but doing “what the patient would want” was a reasonable alternative. Unfortunately, it was seldom clear just what the patient would want, and the parties in discussion about continuing or discontinuing treatment sometimes possessed different beliefs about the patient’s wishes.

The authors concluded that observed differences between doctors and nurses were a function of the professional role played by each rather than differences in ethical reasoning or moral motivation. For nurses, ethical problems were related to their “lower” position on the hierarchical structure: not being listened to by doctors; being expected to remain silent even when witnessing wrong choices; being unable to affect decisions despite their professional assessment and detailed understanding of the patient’s condition. Again, their problem was with their inability to reduce the patient’s suffering, which in turn resulted in their own suffering (experienced as moral distress). Neither group appeared to be aware that hierarchy and a sense of powerlessness were issues for the other.

Georges and coauthors quoted James and Field, who said that when the originating ethics of palliative care are marginalized, the heart and soul of care are endangered. “Expert” values based on medical technologies and psychosocial skills replace the compassionate help. Death is no longer a truth to confront but a process that must be managed as efficiently as possible. Nurses who participated in this study were encouraged in this context to acquire knowledge and skills, whereas development of the moral qualities necessary to care for those who are dying was not addressed. Therefore, they became less sensitive to the moral values in situations. They responded less to problems because their moral values were endangered, mainly because they conflicted with their professional norms and established rules. In situations of pain and suffering, these nurses mainly tried to overcome their powerlessness by a medical approach, overlooking the possibilities of alleviating suffering by an authentic caring attitude based on really meeting with patients.

Studies about the experience of palliative care nurses show that they are looking at patients’ problems in a broad way and trying to see them from the patient’s point of view, not merely from a medical point of view. Caring has repeatedly been found to be the core value that nurses espouse when caring for the terminally ill.

The findings of George and colleagues illustrate the potential differences between applying palliative care in an academic hospital directed by a predominantly medical approach and applying it in the tradition of the hospice movement, where care is at its most fundamental. Time will tell whether Byock’s vision of “cutting edge, medically crisp, but tender and loving care” can be realized.
Issues of Death and Dying

Although the literature has been somewhat divided as to whether care of the dying is a major stressor in hospice palliative care,1–6 recent research in the burnout area has focused explicitly on emotion-work variables (e.g., the requirement to display or suppress emotions on the job, the requirement to be emotionally empathic) and has found these emotional factors do account for additional variance in burnout scores over and above job stressors.22

The most problematic stressor reported by hospice nurses was “death and dying.”27 Greek oncology nurses studied by Georgaki and associates39 believed that they were not sufficiently trained in communications skills and therefore found it difficult to have an open conversation with a patient about his or her forthcoming death. Although a large percentage of the participant nurses believed that it is essential for a patient to know the truth to accomplish a successful therapeutic relationship, their responses showed that they also believed that too much information may lead the patient to feelings of disappointment, despair, and isolation. The authors concluded that Greek nurses wish to be closer to patients and to communicate and share their thoughts and worries. However, they find it difficult to do so because of inadequate education in communication skills.

The difficulties associated with the care of dying persons may also in part result from the close connections palliative care nurses often develop with their patients. As has already been noted, palliative care is, par excellence, care that is given personally or through their education, professional training, mentoring, and supervision.

Boston and coworkers40 noted that dying persons experience disruption of the essence of day-to-day living and challenges to their perception of who they are. Through this process, they gain new wisdom and reshape their sense of meaning in life. A different way of knowing the world evolves, characterized by inner know-how and tacit knowledge that defines the self in relationship to others. Caregivers and others around them “are perceived to be in another place, or don’t seem to be there at all” (p. 248). Patients and caregivers may feel that they just don’t connect. Boston and coauthors40 speak of palliative care as taking caregivers into emotional realms that are neither easy nor comfortable. The caregiver may be permanently changed through this encounter.

Staff in an African hospice had a well-established program that had changed over the years as the country had changed. They themselves were being changed and needed to respond in different ways as a result of the encounters they were having. The hospice director spoke of a family she and her staff were dealing with: the father had died of AIDS; the mother was quite sick with AIDS and was being cared for by her 11-year-old son, who was also HIV positive, as was one of his siblings. His 5-year-old sister was HIV negative. The oldest brother went into the city to earn money to help the family and was killed by rebels. The staff seriously wondered what they could do in this situation in which they had to take the least possible goal and try to make things better in whatever way they could (anonymous personal communication).

In a study comparing nurses working with dying children in Hong Kong and in Greece,26 nurses generally were assigned to work on the unit, rather than choosing this work. They reported helplessness when caring for a dying patient and difficulties in communicating with the children and parents during the terminal phase of the disease. Part of their difficulty related to feeling unable to provide quality care because of the shortage in nursing personnel or feeling unable to alleviate the child’s physical and/or emotional suffering or the parents’ distress. Occasionally, difficulties were also associated with a desperate need to cognitively make sense of childhood death, which appeared “meaningless” because it reversed the perceived order of nature.

Multiple Losses

One does not have to work very long in palliative care before one begins to feel the accumulation of grief related to the experience of multiple losses. Although Mount wrote of the concept of multiple losses within the context of oncology,41 the concept became more recognized with the AIDS epidemic. The concept of multiple losses in AIDS caregivers reflected in part the reality that many caregivers were caring for dying patients while partners, friends, and members of their social network were dying at the same time.24

Garfield42 wrote of alternating between numbness and experiencing grief while caring for people dying of AIDS. Papadatou and coworkers43 reported that the majority of the pediatric nurses working with dying children they studied acknowledged that the impending or actual death of a patient elicits a grieving process, which is characterized by a fluctuation between experiencing and avoiding loss and grief. Greek and Chinese nurses differed in their expression of grief and in how they attributed meaning to childhood death.

Papadatou43 extended earlier work2 to note that the losses nurses experience may extend beyond the deaths of their patients. These losses include

- Loss of a close relationship with a particular patient
- Loss due to the professional’s identification with the pain of family members
- Loss of one’s unmet goals and expectations
- Losses related to one’s personal system of beliefs and assumptions about life
- Past unresolved losses or anticipated future losses
- The death of self
Satisfactions in Hospice Palliative Care

Although work in hospice palliative care can be stressful, it also has many rewards. Current research has focused on the experience of job engagement, which is conceptualized as being the opposite of burnout. It involves energy, involvement, and efficacy. Engagement involves the individual’s relationship with work. As described by Maslach and colleagues,22 it involves a sustainable workload, feelings of choice and control, appropriate recognition and reward, a supportive work community, fairness and justice, and meaningful and valued work. Engagement is also characterized by high levels of activation and pleasure. Clearly, for many caregivers, their work in hospice palliative care is very engaging, as was noted in the research reviewed in this section.

Palliative care is a way of living. Vitality—the capacity to live and develop which is associated with energy, life, animation, and importance—is the core meaning of palliative care. This way of living involves unity with self, being touched to the heart, and personal meaning. Caregivers in Webster and Kristjanson’s study8 found that the lessons learned from their work added meaning to their personal and professional lives. Caregivers were animated in describing their work, and they articulated the importance of their experience in terms of personal growth for patients, families, and caregivers. Interactions with patients, families, and colleagues were meaningful, and the workplace was described as being full of fun. Crucial to the experience of palliative care for the participants was patient and family, holistic care, and the interdisciplinary team.8

Others have described the satisfactions in palliative care as helping patients to find meaning in suffering10,44 and experiencing positive relationships and support from colleagues.45 Despite the difficulties, nurses in units in both China and Greece derived significant rewards from their work with dying children.26,28 They reported a deep sense of satisfaction from having contributed something significant in the care of each child. They believed they were doing a very difficult but also meaningful job. They often described their role as “unique” or “special” by comparison to the role of nurses who worked in other units. In both units and both cultures, nurses’ involvement and intimate encounters with children were recognized and appreciated by the patient’s family.26,28

The nurses interviewed for this study also validated this concept of engagement in their work. Deanna Hutchings, who was quoted earlier in this chapter wrote in her letter,

“...something happens on this intimate journey, with its risks and sadness and fear and joy, with its naked acknowledgment of the mystery of our human existence, that sustains health-care providers far beyond the demands of caring for a particular patient.”46

Yes, something happens. As nurses, we need to begin to explore and explicate what that sustaining “something” is and how that transformative “something” impacts seasoned nurses in this field.

I liken the importance of identifying the nourishing parts of this work to acknowledging the beautiful moments that commingle with difficult moments in our work, and in our lives. While walking in the Victoria rain yesterday morning, I was treated to a stunning rainbow, and I thought, hospice nursing is like that. We can focus on examining the “rain” of stresses in this work, but we can also look up, and savor the exquisite rainbow of tender moments and courageous acts to which we bear witness in the course of our nursing practice with dying persons. I believe we need to acknowledge the rainbows and inform one another about the rainbows.

Coping in Hospice and Palliative Care

In the author’s earlier study of more than 600 caregivers from around the world, the primary personal coping mechanism was a sense of commitment, control, and pleasure in one’s work.4 This characteristic is strongly linked with Antonovsky’s sense of coherence,47 with Kobasa’s personality construct of hardiness,48,49 and with Hirshberg and Barasch’s sense of congruence.50

Compassionate Caring and Service

More recently, Carolyn Myss51 has spoken of the difference between a job, a career, and a vocation. She refers to the chakras—sources of energy in the body having to do with various aspects of life.

A job takes care of the lower chakras, the first and second chakras (having to do with safety, security, emotions such as fear and anger, putting a roof over one’s head and food into one’s body). A career takes care of the third chakra (the ego, one’s power source in the universe). A vocation involves the higher chakras, or service to one’s soul (the heart chakra, giving and receiving love; the throat chakra, speaking one’s truth and getting in touch with one’s creativity; the third eye, seeing what we cannot see with our human eyes; and the seventh chakra, connecting with the Divine, or the universe).

Caregivers in hospice palliative care can see their roles as a job, a career, or a vocation. This perspective may further understanding of the different approaches caregivers take. For some, hospice palliative care is a job—simply a way to earn a living. For others, perhaps some of those nurses described by Georges and colleagues,11 palliative care is a career, feeding their ego. This is not to say that the work they do is not good, but that in some ways the work is more about themselves and their own
satisfaction than it is about entering into a deeply caring relationship with patients. These nurses have been taught skills, as opposed to reflecting on values. By mastering nursing diagnosis and being able to speak with physicians in a manner they believe is appropriate to an academic setting, these nurses can derive a great deal of satisfaction. However, some would say that something is missing from their care—which perhaps explains why so many staff were leaving the unit. For many caregivers in hospice and palliative care, their work is a vocation—service to their souls. In truly meeting the needs of others, they are meeting the needs of their own souls.

Dr. Rachel Naomi Remen32 writes, “Basically service is about making the work personally, letting the lives that touch yours touch you” (p. 197). She contends that service is a relationship between equals. When you serve, the work itself keeps you from burnout. Unless you let the patients touch you, you will never last in this work.36 Protecting ourselves from loss rather than grieving and healing our losses is one of the major causes of burnout37; “We burn out not because we don’t care but because we don’t grieve. We burn out because we have allowed our hearts to become so filled with loss that we have no room left to care” (p. 52).

Remen speaks of compassion, which, she says, “begins with the acceptance of what is most human in ourselves, what is most capable of suffering. In attending to our own capacity to suffer, we can uncover a simple and profound connection between our own vulnerability and the vulnerability in all others. Experiencing this allows us to find an instinctive kindness toward life which is the foundation of all compassion and genuine service.”32 This concept recognizes the reciprocity that is inherent in the caring relationship. Jean Watson, a nurse theoretician, states, “When both care providers and care receiver are co-participants in caring, the release can allow the one who is cared for to be the one who cares, through the reflection of the human condition that in turn nourishes the humanness of the care provider. In such connectedness they are both capable of transcending self, time and space.”34

An image of compassion that has become central to the author’s professional work and life is The Man in Sapphire Blue, an illumination that was received by the 12th century mystic, Hildegard of Bingen. Mathew Fox33 writes of this image and states that the color of the heart chakra is green. Hildegard built her entire theology on **viriditas** or “greening power.” She felt that all creatures contained the greening power of the Holy Spirit, which makes all things creative and nourishing. In her picture of the Man in Sapphire Blue, the man’s hands are outstretched in front of his chest. This gesture is an ancient metaphor for compassion, because compassion is about taking heart energy and putting it into one’s hands—that is, putting it to work in the world. This is the work of healing and assisting. As Fox33 described the image, “An energy field surrounds the man. Clearly this is a man whose ‘body is in the soul’ and not whose soul is in the body. Both Hildegard and later, Meister Eckhart, spoke of the body/soul relationship in this imagery of shared energy systems, with the soul energy being the greater entity” (p. 23). In the illumination, there is “an aperture at the man’s head, so that this powerful healing energy can leave his own field and mix with others—and vice versa” (p. 23).

Recent 20th century science found “evidence” of this shared energy “seen” by a mystic in the 12th century. Dr. Michael Kearney, a hospice physician, uses concepts in the “new physics”44 to describe the integration between the traditional medical model and the healing model that can be applied in palliative care and its relevance to the relationship between the caregiver and the patient. “The quantum idea that ours is a participatory universe has implications for carers. Although there are still subjects and objects within the healing model, the boundaries may not be as clear as they were within the medical model. Caring now becomes a dynamic event. While the roles of ‘carer’ and ‘patient’ remain, there is also an interweaving of the two. The term ‘clinical objectivity’ is joined by that of ‘clinical subjectivity’, acknowledging a shared dimension to the healing encounter.”44

Harper21 says of stage VI in her model “The Doer” (as described in Chapter 2 of this textbook) that to “some extent Doers have learned how to gather from the universe what they need to do their work. Their clients recognize something in them and feed back this information that can then be used to help others” (p. 101). Another example of this is provided by Vachon.56

Several years ago, I was diagnosed with stage 4 non-Hodgkin’s lymphoma. My odds of survival were 1:4. This was a spiritually transforming experience which led to many changes in my life, including leaving my position in an academic setting. Through this experience I felt a connection to God, the universe, and the people I had worked with who had gone before me. I started using these new-found insights in my clinical practice through the use of meditation and prayer with clients.

The following story from the author’s own experience is used with Andrea’s permission.

**CASE STUDY**

**Andrea**

At 27, Andrea was diagnosed with soft tissue sarcoma. Within a few months she had a local recurrence, and within another few months she had metastatic disease in her lungs. She was told that she would have chemotherapy, which would probably not work very well because of the nature of her disease. Andrea was told that her disease showed up as a matrix in her lungs and that even if the cancer did disappear it would be hard to see this, because the matrix would continue to be there. At the end of chemotherapy, she would have surgery and would have the remaining cancer removed. She was told that a year later her cancer would recur, and again she would have chemotherapy and surgery. Andrea was understandably very upset by this news. She was referred for help in dealing with this new diagnosis.
We did a series of meditations before and during chemotherapy. After her first chemotherapy treatment, Andrea developed febrile neutropenia and was admitted to a local community hospital. There she became quite ill and during this time saw a vision of the face of God. At around the same time, the author was walking and listening to spiritual tapes including a favorite song with the words, “You shall see the face of God and live.” When Andrea returned for her second chemotherapy treatment, her oncologist could not find her previous X-ray films but said that if he didn’t know better he would think that her chest X-ray was normal. He would, however, continue with chemotherapy and then she would have surgery at the end of chemo. When chemo finished, there was still no evidence of disease, so there was no surgery. A year and a half later, Andrea is well; she has moved, married, and begun a new career.

Was there a connection between the meditations, the vision, the tape, and the remission? We will never know, but sometimes, as we are able to access some powers beyond our own, such occurrences happen more than they used to before we accessed such powers.

Environmental Coping in Hospice Palliative Care

Despite the fact that the stressors of staff in hospice palliative care have been documented from the beginning of the field, there is no substantial body of work documenting the impact of programs of intervention. This section reports on some recent research as well as some programs that hold promise.

Teamwork

Chaplain and psychotherapist Peter Speck noted that the ability to “contain” powerful reactions and strong emotions is an essential part of all caring relationships. As quoted by Kearney, “The most significant factor in creating containment for the person in suffering is the web of caring relationships that establish security and trust with that person. However, the containment that is created by interprofessional teamwork does not simply come about because a number of different disciplines happen to be involved in that patient’s care and treatment. The container has to be built, a process which involves deliberate and conscious effort” (p. 88). Workers in each discipline involved in the patient’s care must have a clear sense of their own professional identity, including their profession’s strengths and limitations. There must also be an acknowledgment of and respect for the contributions that other professions have to offer:

There must also be an awareness of shared areas of care, where close communication and cooperation are essential to avoid duplication of effort, interdisciplinary territorialism, and confusion or ‘flooding’ of the patient. . . . The process of team self-awareness comes through individual disciplines meeting together and with regular interdisciplinary team meetings. [In addition,] each discipline needs to be fully versed in the Hippocratic approach as it applies to its domain of clinical responsibility and to be effective in its therapeutic task. Such competence helps to create trust with patients, to lessen their sense of fear, and to increase their sense of security. (p. 88)

Kearney suggested that the presence of an outside facilitator, experienced in team management and psychodynamics, can be invaluable in the early stages of team building as well as when dealing with difficult issues arising from the care of a particular patient.

Regular opportunities to meet and talk together can also help teams to develop a respectful understanding of differences in respect to specific situations. For example, Redinbaugh and associates noted that physicians and nurses may prefer different coping strategies and may have different personality structures that lead to differences in response to patient deaths. These authors drew on Holland’s theory of occupational interest to propose a model of grief that might help in understanding team differences. Individuals have natural propensities and aversions for minimizing grief reactions. Emotion-focused coping would be used by those with a high “Social” score and low “Realistic” score. They were likely to talk with others about their grief. Those with a high “Artistic” score with a low “Social” score would attempt to understand their grief through its depiction in literature and the arts. High “Conventional” scores paired with low “Investigative” scores are reflective of those who are less likely to dampen their grief with alcohol or drugs and more likely to use personal faith to resolve their grief.

Both teams and individual caregivers need to find ways to manage their grief in order to survive in this work. The approach each individual uses may be different, but there needs to be a way of grieving the losses that occur.

Models of Team Intervention

The development of supportive, collaborative work relationships is fundamental to enhancement of self-efficacy and self-esteem. It is important that organizations create the opportunity for ongoing support and that nurses have the time to attend support sessions, especially for those working alone in the community. Support may be provided through team meetings, easy access to consultants, a buddy or mentor system for ongoing support, and the opportunity to debrief after critical incidents. Ideally, caregivers would also be provided with supervisors or mentors who could assume a role similar to that which Harper had with the oncology social workers with whom she worked.

Although support groups are recommended almost as a panacea for either team stress or problems with patients, their effectiveness has generally not been well researched. Van Staa and coworkers described an intervention in a new palliative care unit in the Netherlands. A carefully designed training
program and staff support activities were meant to enhance personal growth, to give emotional support, and to deal with death and bereavement issues. The interventions did not involve mutual collaboration, practical problems, managerial and communication skills, or the skills needed to deliver complex palliative care. There was a cultural difference between the external consultants, who embraced a relational therapeutic world view, and the hospice staff, who came from a rational, technical, hospital environment. To be successful, the former approach involves complete trust and openness. Not all staff members were convinced of the value of the nondirective approach. In addition, a therapeutic group is fundamentally different from a group that has to work together after the session. The researchers suggested that future leaders should focus on content as well as process issues. They also suggested that adequate resources, a supportive management structure, an extensive educational program, and attention to individual needs should accompany support groups. These issues have been identified earlier, so it is worth noting that they still exist.

Medland and colleagues described an intervention with 150 members of the multidisciplinary team at Northwestern Memorial Hospital. They noted that, particularly during times of uncertainty and change, social networks played a key role in protecting staff against burnout. Community building in the workplace is touted as a defense against the constantly changing environment, according to Parker and Gadbois, who suggested encouraging “community in the workplace” as a value in creating a meaningful and rewarding work environment. Medland’s group suggested that the failure of management to address this “human side of work” and the need for support and a supportive work environment intensify stressors and put employees at risk for developing the burnout syndrome.

Medland and colleagues also described an intervention to interrupt the cycle of turnover on a state-of-the-art oncology unit. The intervention included an array of tactics and strategies, with the development of social support through enhanced collaboration and the cultivation of stress management strategies being high on the list. Other issues addressed included compensation, benefits, flexible scheduling, management, and staffing that is in line with the demands of patient acuteness. Issues surrounding patient intensity exerted the most powerful impact on turnover. The leadership team set out to create a healthier work environment. The goal was to create an environment wherein care providers would be infused with an intense sense of gratification and fulfillment and where a passion for service and excellence would prevail (p. 50).

A series of one-day Circle of Care retreats addressed specific concerns pertinent to improving the psychosocial wellness and skills of care providers. A total of 150 multidisciplinary team members attended this program over five sessions. These workshops were seen to be the first phase of a comprehensive, ongoing psychosocial support program for staff, tailored to address the psychosocial demands of oncology nursing. The day included interactive and informal presentations about staying well, managing losses, developing stress management skills and strategies (e.g. relaxation, journaling), facilitating bereavement, cultivating team effectiveness, group support, story telling, and an art therapy session, called “All Gifts Differing,” that offered a reflection of the unique attributes staff members bring to the work setting.

The intervention beyond the Circle of Care workshops used the FISH! management philosophy, which emphasizes the power each person has to improve the work environment. In addition, the program used the CARES philosophy to provide a framework for incorporating the stress management and self-care skills staff members had learned into their practice. This philosophy involves the following:

C — creation of a community of care, as opposed to feeling solely responsible for meeting the needs of clients; caring for each team member unconditionally; being cognizant that the stress of the day depends more on work group than on patient care assignment
A — awareness of the signs and symptoms of stress and burnout in self and others, and a recognition that stress management needs to be as integral a competency as preparing chemotherapy treatments
R — reinforcement of the importance of relaxation and rejuvenation as a self-care skill so that the needs of others can be met effectively
E — emphasis on regular aerobic exercise and healthy eating
S — spiritual awareness and reconnection to whatever is personally meaningful: reconnect to faith and be playful and attentive to the “spirit” at work.

After the Circle of Care retreat session, a Circle of Care Bereavement Council Group composed of alumni was convened to discuss and implement strategies discussed at the retreat and to develop rituals to be associated with bereavement care, for staff as well as bereaved families.

This project has not yet been evaluated, but staff retention has improved. Plans are underway to measure the effectiveness of the program through increased overall patient satisfaction, psychosocial patient satisfaction, and spiritual patient satisfaction scores. Measurement of the level of staff psychosocial wellness, as evidenced by follow-up human services surveys, is planned for the future. Most importantly, staff members will be monitored for changes in behavior that reflect the use of positive coping strategies and constructive self-care behaviors.

Another model for shifting established patterns is being conducted in the European Union, with a goal of improving the interaction between palliative care mobile teams (PCMT) and the hospital staff personnel with whom they interact. In this model, recognizing the full range of convictions held by persons in a hospital setting, the concept of palliative care/terminal care has been bolstered by the concept of “continuous care.” Continuous care tends to articulate both curative and palliative procedures rather than setting one form of therapy against the other. Continuous care is a multidisciplinary approach that brings together medical, social, and psychological concepts (as well as spiritual beliefs for some people) in
a continuum starting from the time a grave illness is announced and on to the end of life, without any lapse. In that context, the role of the caregiver who is member of a PCMT is often transformed into one of interface and training.

The results analyzed from several studies supported the use of specialist multiprofessional teams in palliative care to improve the quality of life of patients with advanced cancer and their families. However, there were some difficulties in incorporating this concept into general hospital settings. In order to have mutual benefit, this project was undertaken with the following main research objectives:

- Identify the internal and external mode of operation of seven PCMTs in Europe
- Identify the strong values and principles of the hospital PCMTs
- Examine the background and evolution of these teams through their different traditions and in light of the different cultures in Europe
- Identify areas of resistance to the values and principles of palliative care
- Identify the problems of integrating hospital PCMTs
- Update and modify the contents of the philosophy on palliative care in line with the reality of hospital institutions
- Find new organizational and teaching strategies to improve the integration of PCMTs into hospital institutions and to promote continuous care.
- Articulate the tension between the ethical, sociopolitical, and training dimensions of the PCMTs’ activities in order to reinforce their impact in the hospitals

This project was envisioned to be the first step in a large European public health campaign to foster research in prevention of suffering. The research project had several unique components, including ethics mediation as a part of the research design. Educational programs involved developing an interactive team learning style based on understanding of the different learning styles of the PCMT and the hospital-based team and learning to communicate in the “other’s learning style.” The program was developed based on research showing that the PCMTs needed to assume a different learning style with hospital staff. Four months after the educational program was developed, the PCMTs reported improved interaction among themselves and with the hospital staff personnel.

Oberle and Hughes suggested that doctors and nurses need to engage in moral discourse so that each might understand and support the ethical burden carried by the other. Administrators should provide opportunities for discourse to help staff reduce moral distress and generate creative strategies for dealing with this problem.

Educational Interventions

Georgaki and associates suggested that the academic curricula in nursing should be given further attention and reorganization to diminish feelings of insecurity when communicating with palliative care patients and their families. Educational strategies for preparing nursing students to care for patients with cancer should be further explored and addressed. In the future, nurses should be systematically provided with (continued) training programs in which they learn how to communicate effectively in relation to patients’ emotions and feelings and how to integrate emotional care with practical and medical tasks.

Medland and colleagues noted that, “Appreciating oncology nurses as a cherished resource in the healthcare setting mandates a comprehensive approach to their retention, not only by providing for their technical competence and educational needs, but also by including programs that allow them to creatively manage the emotional components of their role and to learn and cultivate life- and practice-enhancing skills. Novice nurses in particular require clinical and psychological mentorship as they work toward becoming oncology nurses and find themselves highly vulnerable to the profession’s many intrinsic stressors” (pp. 47–48).

In the United States, White and coworkers studied members of the Oncology Nursing Society in four states. Only 26% said they had an excellent level of preparation to effectively care for a patient and family during the end-of-life period; 54% reported a good level of preparation, 17% indicated a fair level, and 4% reported little preparation. A total of 553 respondents (74%) indicated that they had received continuing education related to end-of-life care in the last 2 years. This training ranged from more than 4 hours (55%) to 1 or 2 hours (17%).

More than half of the 553 respondents who reported receiving some continuing education said that the information they received was useful and current, and the majority indicated that they were able to use the education in their practice. Although most respondents rated their ongoing education as excellent, very good, or good (76%), one fourth of the group rated their education as fair to poor. Combining the latter group with respondents who had no end-of-life continuing education indicates that almost half of the respondents did not participate in end-of-life continuing education or believed it was of dubious quality.

Barnard and colleagues noted that education for palliative care involves the art of building and sustaining relationships and use of the self as a primary instrument for diagnosis and treatment. This involves psychological risk-taking that may be unique in the health field. This is the type of education that must be undertaken for professionals to strive and thrive in palliative care.

Personal Coping Mechanisms

Payne found that two coping strategies were related to reduced burnout: (1) a problem-focused strategy, or planful problem-solving, and (2) an emotion-focused coping strategy, or positive reappraisal, which describes efforts to create positive meaning by focusing on personal growth.

Given that the whole person of the caregiver is involved in palliative care, the caregiver needs to understand how to take...
care of himself or herself in order to effectively work in the field. With knowledge about oneself and the ways of nurturing oneself, the caregiver can then teach and serve as a role model to patients and families on how to care for themselves.

Webster and Krisjanson\textsuperscript{9} found that, in the Australian caregivers they interviewed, palliative care was seen as a way of living. The individual caregivers made a personal connection between the lessons of the workplace and application of these lessons to personal life—making a decision to live one’s life congruent with work experience. Of interest is the fact that in a study of people with an unexpectedly good outcome to metastatic cancer, a sense of congruence was found to be important.\textsuperscript{50}

### Lifestyle Management

Table 56–1 lists a number of lifestyle management techniques that are helpful for continuing to work in stressful situations.

Remember the Serenity Prayer at work: “God grant me the serenity to accept the things I cannot change, the wisdom to change the things I can, and the wisdom to know the difference.” Sometimes work-related problems can be solved; at other times, leaving the work environment, taking the wisdom gained, is a good solution.

Space does not allow for the many anecdotes received from participants regarding their ways of coping, so one anecdote is given to illustrate the many creative ways in which caregivers cope:

This particular nurse was a student of the author’s many years ago. We reconnected at a hospice meeting where I was speaking. She reflected that she had hated the course in Psychiatric Nursing that I taught in the early 1970s. However, she had become a psychiatric nurse and then a hospice nurse in a rural community. Now our paths crossed again. “I found a very small space that was being used for storage. It had windows, so I pushed to get it for my office. It has enough room for three chairs, a small desk, and my computer. I filled it with plants that reach to the ceiling. The patients and families love it. When I get fed up with dealing with death, I take a breather and garden. One day, I was making an azalea into a bonsai plant. I was bent over a wastebasket in the coffee room, digging in a pot loosening roots, when I looked up to see my bosses looking at me. I looked up and said, ‘OK. I’m fed up with death, so I’m doing life.’”

Many of the lifestyle management techniques listed in Table 56–1 involve some type of energy work—meditation, yoga, qi gong, reiki, nature, and so on. Cumes\textsuperscript{66} noted the importance of the caregiver’s achieving personal balance so that more effective healing can occur. This process happens in part through intensifying one’s own internal energy, to enable one’s own Inner Healer. The Inner Healer, who has been wounded through various life experiences from the past as well as through education, clinical encounters, and the workplace, needs to be able to replenish himself or herself in order to bring the caregiver’s healing potential into the clinical encounter.

### Spirituality and Religion

Our Inner Healer is enabled if we intensify our internal energy, life force or Prana (breath, in yoga), or Qi (pronounced “Chi,” in Taoist philosophy). In Hebrew, this life force is called Ruach, which also means wind, breath of life, soul, or spirit—the mysterious unseen and irresistible presence of the Divine Being or the Spirit of God.\textsuperscript{66} This requires some form of inner practice, either physical or mental, such as prayer, meditation, imagery, yoga, tai chi, qi gong, or breath work.

Religion and spirituality have been found to be helpful to caregivers. In a study at Memorial Sloan Kettering Cancer Center,\textsuperscript{67} nurses were found to be more religious than other groups. Oncologists were more religious than fellows. Those who were “quite a bit” religious to “extremely” religious had significantly lower scores on diminished empathy or de-personalization and lower emotional exhaustion on the Maslach Burnout scale.\textsuperscript{53} In a study of 155 members of the Israeli Oncology Society, spiritual well-being, extrinsic religiosity, and education demonstrated significant direct relationships in a path analysis toward attitudes toward spiritual care. Spiritual well-being of the nurse was the strongest predictor of Israeli oncology nurses’ attitudes toward spiritual care.\textsuperscript{68}

One of the most important spiritual practices the author uses is the Prayer Wheel, which was developed by Dr. John Rossiter Thornton\textsuperscript{69} (Figure 56–2).

</table>
Conclusion

Nurses work in palliative care for a variety of reasons. Some may regard the work as simply a job, perhaps to be done for only a few years so as not to become overly involved in the stress associated with caring for dying persons and their families. Others may see hospice palliative care nursing as a career. It may feed their ego to be able to get on top of symptoms, resolve psychosocial issues, communicate well with other disciplines, and perhaps even achieve recognition as an expert in their field. For others, hospice palliative care nursing is about service to their soul. As the Prayer of St. Francis says, "It is in giving that we receive."

To continue to work in this field, however, one cannot focus exclusively on giving, or else one exhausts one resources. To care for others, one must be sure to care for oneself and to nurture the various aspects of one’s mind, body, soul, and spirit. Learning to care for oneself so as to care for others—hopefully in a work environment that has a reasonable workload, offers community, is fair, gives one appropriate rewards as well as some control and power, and is congruent with one’s values—can be an enriching experience. Organizations will hopefully provide mentoring, education, and supervision to help nurses progress on the path to Harper’s Comfort-Ability12 in hospice palliative care nursing.

Dealing with dying persons and their families can be difficult, but it can be extremely satisfying and rewarding as well. We need to grieve our losses when patients die, but we can also be grateful for having had the privilege of accompanying them on this very special journey, hoping there will be others to accompany us when our time comes, as indeed it will.

Key Points

- The nurse's ethical responsibilities in caring for patients at the end of life are actualized in all dimensions of care.
- Acts of truth-telling, respect for autonomy, and nonabandonment reflect the highest standards of nursing care.
- Issues of futility and treatment decision-making should be viewed within the context of the patient's goals of care.
- The allocation of health care resources has the potential to markedly affect future care.
- Nurses must assert their role as full members of the interdisciplinary team in discussions of moral issues.

Technological advances in the diagnosis and treatment of chronic disease have resulted in longer lifespans and, in many cases, an extended period of dying. This ability to prolong life has been almost seamlessly integrated into the medical profession's philosophical approach to treating disease as an adversary that can and must be conquered. The value of existence for its own sake, a false sense of security about technology's ability to rescue, and the human need to maintain hope and delay the end of life have obscured and postponed the inevitable need to confront critical issues.

Solomon and colleagues demonstrated that physicians frequently recognized that they were overtreating patients at the end of life but did not know how to stop. Means to a Better End: A Report on Dying in America Today confirmed that significant numbers of patients continue to end their lives in a hospital setting and that 18% to 34% of patients older than 65 years of age have seven or more days in intensive care units (ICUs) during the last 6 months of life. The ability to prolong life has outpaced medical, philosophical, bioethical, and societal efforts to reach a value-based consensus on the goals of and criteria for care across the illness continuum. Ethical dilemmas on macro and micro levels emerge daily as the debate on extending life versus postponing death continues. These dilemmas are normative over the continuum of care and continue in the palliative care arena, where decisions about life-supporting and life-ending interventions are made on a daily basis.

Palliative care as a viable and worthwhile choice for those at the end of life is often obscured by the focus on technology. From a societal perspective, demographic trends separate the generations, and cultural norms may no longer validate caring for one's aging family members in the home setting. Consequently, many individuals and families have not lived with or cared for a dying person. A generation that has no practical or emotional experience with the act of dying is bound to be uncomfortable with decisions that must be made and insecure about delivering care at home. Patients and families continue to choose interventions that can be delivered only in the acute care setting.
setting, as opposed to a death at home under the care of a family member or significant other.2

The issues of truth-telling and informed consent, withholding or withdrawing treatment, the definition of ordinary versus extraordinary medical intervention, and the right to assistance in ending one’s life because of an unacceptable health condition are becoming further removed from those individuals most effected by the decisions. The argument is persuasive that these issues must be addressed through conversations, debates, and discussion groups in order to clarify individual and societal rights regarding end-of-life care. The inability to agree on a health care decision-making paradigm that allows the expression of diverse values endangers the right of individuals to make personal choices about health care.

The rising costs of medical care have introduced another dilemma central to the whole spectrum of debate. The allocation of health care resources described as finite suggests that there can be limits to medical intervention. The demand that society bear the cost of every possible medical intervention returns the debate to the most basic of issues: Are there circumstances in which existence is no longer intrinsically valuable? Whose values should drive the goals of care? How should these decisions be made, and by whom?3

These debates largely began with cases in which patients demanded, first to their doctors and then to the courts, to be rescued from the technological imperative. Karen Ann Quinlan’s family contested her life on a ventilator, asking that this be rescued from the technological imperative. Karen Ann Quinlan’s family requested that a feeding tube delivering enteral nutrition be discontinued.4 Nancy Cruzan’s family requested that a feeding tube delivering enteral nutrition be discontinued.5 These kinds of cases, in which the patient’s wishes were not known or documented or the patient’s and family’s wishes were not honored without resorting to the courts, were common in the 1970s and 1980s. That ongoing public dialogue and legal activity sensitized the lay public to the concept of autonomy, and health care consumers began to insist on greater control over health care decision-making. The courts redefined what constituted extraordinary treatment and coun- tenanced the wishes of patients and their families if patients were unable to speak for themselves, even to the extent that life-sustaining treatment could be withdrawn.6 Recently, the Terry Schiavo case7 reopened the debate about who can make life-ending decisions and under what circumstances.

One’s abilities to understand current legal statutes, to comprehend ethical discourse, and to clarify one’s personal philosophy can be strengthened by a review of ethical methods and terminology. Nursing is not isolated from bioethical conflicts, and, in fact, nurses have significant responsibility in understanding and articulating an ethical rationale for decision-making and consequent actions.

Traditional Methods of Ethics

Ethics asks these questions: What is the right act, the good human moral gesture, and what makes it so? What is the meaning of a good life, and how is it made? How is justice best achieved among competing moral appeals? Who ought people to be, and how ought they to treat others, and what are the criteria for knowing such things? Ethics seeks to logically justify choices for right behavior, rules, and activities, particularly in situations that challenge established norms of behavior or require new paradigms for judging behavior. It is this understanding of ethics as a methodology that distinguishes it from morality, rules of proper conduct, or descriptions of cultural norms.8 In its normative capacity, ethics is an applied theory for the practice of medicine (bioethics) and the conduct of research, business, and political actions.

Ethical inquiry, in its interpretation of any act—for example, the judgment that it is “the right thing to do”—traditionally has evaluated (1) the moral agents and their character; (2) the motive for the act itself; or (3) the effects of the action on others, with the assumption that humans are rational beings with the ability to justify their actions. Although this process historically has relied on sociability, accountability, conscience, and rationality, certain assumptions are currently being challenged. For example, Can there be a single standard for rightness of action in a world so profoundly diverse? Can there be, if not agreement on the definitions of a good action, agreement on a common language of ethics?

The various ethical methods9 have emerged at specific historical periods and are shaped by the culture, class, and gender of the theorists. At best, each is useful as a starting place for defining one’s approach to ethical dilemmas.

Virtue theory, the study of character attributes that are necessary for the achievement of a good life, was developed in the Greek philosophic tradition. The virtues described as good include courage, loyalty, and civic friendship. They are developed through training or role modeling a virtuous person’s behavior. The theory was expanded to include compassion, merging the Greek ideal with Christian philosophy. Palliative care, with its emphasis on caring, kindness, and respect for another person (virtuous attributes), is well suited to this methodological approach.

Deontological ethics focuses on rules and motives for behavior. It argues that certain qualities that are innate to a human being or a social order require specific obligations or duties. These obligations can be based in God’s law—as in rabbinical text, with its emphasis on a life of commands and obligations to those commands—or in essential unconditional imperatives whose moral worth is to be found in the rule itself—for example, Kant’s imperative never to lie. This approach incorporates the bioethical requisites to “do no harm” (the principle of nonmaleficence) and to “do that which is good” (the principle of beneficence).

Consequentialism is based in the 19th-century utilitarian philosophic tradition. The virtue of a behavior bears a direct relationship to its outcome. In contrast to deontological theories, which are rooted in commitments, essential obligations, or promises, consequentialist thinkers argue that assessment of a right action should be based on the possible outcomes of that action. In this theory, individual rights are more questionable,
and individual freedoms depend on the outcome for the general good, the good for the greatest number, or the avoidance of harm to the most. This approach would argue that a dying individual’s right to autonomous choice about assisted death is superseded by concern for society as a whole and the fear of imposing assisted death on those who do not wish for that outcome.

Ethics and Palliative Care

An examination of ethical issues in palliative care requires an articulation of the standard to which all practice is compared. Ethical dilemmas surface as those comparisons draw attention to the inadequacies of practice. For an ethical standard to be meaningful, it must reflect a comprehensive approach that simultaneously allows for each individual’s particular needs. The extraordinary spectrum of requisites, from the most basic of physical care concerns to the broad issues of existential distress, reflects the daunting ethical responsibilities that are integral to palliative care.

Cassell succinctly described ethical obligations in health care as accountability for diagnosis and treatment plans made in terms of the patient rather than the disease, balancing quality versus quantity of life, and minimizing suffering for the patient and family. Ferrell’s quality-of-life model, which identifies the essential components of physical, psychological, social, and spiritual well-being, is comprehensively reflected in the Five Principles of Palliative Care (Table 57–1). These principles translate larger obligations into specific accountabilities and can serve as a “checklist” for any health care professional caring for persons at the end of life.

The need for improving care at the end of life remains a constant in the midst of any ethically focused discussion. The results of the landmark Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatment (SUPPORT) study, which examined how people died, were discouraging. The majority of people died in the hospital, often alone and uncomfortable, while receiving medical intervention they did not want. The current inadequacy of formal professional training, despite excellent supplemental training provided by the Education for Physicians on End of Life Care (EPEC) course for physicians and End of Life Nursing Education Consortium (ELNEC) course for nurses, and the subsequent lack of a cadre of health care professionals with palliative care expertise, impede excellence in care and interfere with the professional’s ethical obligation to provide that same excellent care.

These variables have contributed to a decline in the public’s belief in the integrity of the medical care system and in confidence that the physician “knows best.” The health care team is increasingly being held accountable for the delivery of skilled palliative care. Patients and their families are asking for the information necessary to make informed decisions and the right to be involved in the decision-making process.

Ironically, as this higher standard of accountability for quality care has emerged, end-of-life care is shifting from acute care to outpatient settings. Patients who are no longer candidates for active medical intervention are being discharged with complex care requirements. As a result, patients and their families are assuming responsibility for care that was previously delivered by health care professionals.

Demographic mobility, separation and divorce, changing cultural mores, and a decreasing sense of accountability for the care of elderly parents have altered the definition of family and the availability of support systems. Adequate caregivers for dying persons may not be readily available if their spouses have predeceased them; adult children may be geographically distant and dependent on dual incomes; or the primary caregiver may also have health problems. Even more caregivers will be needed in the future, given increased life expectancy and the aging of the population. Palliative medicine practitioners will continue to be ethically challenged to provide safe care to increasing numbers of patients.

The realities of the current health care delivery system, including a critical nursing shortage, demand even more of nurses. Home health, hospice, and extended care facilities rely heavily on nursing assessment, intervention, and presence to ensure high standards of supportive care. The profoundly existential issues that are the essence of the palliative care experience can be double-edged swords for the nursing profession. Although they present valuable caring opportunities, they may simultaneously generate moral distress—an inability to provide care valued as most appropriate or an inability to “do the right thing.” These conflicts may reflect differences in perspective from those of the patient, the family, or other members of the health care team, and they occur, ironically, in the context of providing care that may preserve or lengthen life or, conversely, hasten or end life.

Case Study

Michael, a Man Who Wanted “All the Life He Could Get”

Michael was diagnosed with extensive lung cancer in his mid-forties. He had recently received a significant promotion at work and had two young children. He declared from the
beginning that he wanted everything possible done, but the treatment regimen had not slowed disease progression. As he began to deteriorate, he insisted on continued chemotherapy, and his oncologist continued therapy. The nursing staff who were administering the chemotherapy felt very conflicted about this intervention. Although they wanted to honor his wishes, they believed that continued chemotherapy would cause more harm than good. The clinical nurse specialist (CNS) caring for Michael understood his wish to hang on to life and wished it were possible. She had been involved with Michael and his family for several months and felt equally uncomfortable with continued therapy that contributed markedly to the “suffering quotient.” Late one night, Michael was open to conversation, and they had a frank discussion about the dilemma at hand. She spoke of quality of life, time at home with his family, and finishing up personal business as valuable goals. He spoke of the future that he wished could be. They collaboratively made a list of possible opportunities for Michael that were not dependent on further therapy. He wavered over the next several days as he continued aggressive supportive therapy, but he was ultimately discharged home that week after talking at length with his physician and his minister. The CNS continued to see him at home and supported him as he made his way through the list of “opportunities.” He died, still wishing that more time had been available but thankful he had spent time with his family.

Ethical dilemmas emerge across the spectrum of care as nurses endeavor to provide the best possible physical and psychological care, communicate appropriately and honestly with the patient and family, provide culturally competent care, assist patients and families in making decisions to withhold or withdraw treatment, and respond to requests for interventions that may conflict with their personal value systems. As each patient and significant other confronts the realities of mortality and fragility, and as each nurse intervenes in the crisis, meaning and shape emerge from those choices made at the bedside. How one decides to act in any particular case is really the measure of how far one is willing to explore alternative diagnoses and treatments and of what one considers appropriate at the end of life.

Changing Role of the Nurse

As the health care delivery system has changed, historic role expectations have been adapted to meet the needs of patients and families, professional staff, and the health care delivery system itself. The multidisciplinary approach that is common in the palliative care arena requires that each team member contribute to the overall sum of excellence in patient care. Although traditionally the nurse’s role was to carry out the physician’s orders, that expectation has been expanded. The varied sites of palliative care, the nurse’s primary role in case management, and the changing parameters of the health care delivery system require that nurses be expert practitioners. Assessment, intervention, evaluation, and reevaluation in physical and psychological arenas are accepted nursing roles. It is not unusual for nurses to practice autonomously in providing expert symptom management under established standards of care. Expert nurses adjust medications and dosages, make multidisciplinary referrals, and engage patients at the most existential of levels as part of a normal day’s work.

The enlarged arena of nursing responsibility translates into greater ethical obligations as well. The American Nursing Association (ANA) supports the role of nurses in facilitating informed decision-making for patients making choices about end-of-life care. In fact, it is not unusual for nurses to be involved in discussing advance directives, prognoses, do-not-resuscitate (DNR) decisions, and a myriad of other palliative care issues. Distinguishing quality versus quantity of life, providing objective feedback about the patient’s current status, articulating outcomes of health care decisions, and offering to be present as health care choices are clarified are activities that demonstrate nurses’ commitment to these significant responsibilities.

Case Study

Edgar, a 72-Year-Old Man Undergoing Chemotherapy

Edgar was a 72-year-old man in blast crisis. He was admitted to the hospital on a weekend when his oncologist was out of town. The covering physician was prepared to begin the chemotherapy his colleague had planned; although he had reservations because of the toxicities involved, he did not know the patient and felt uncomfortable changing his colleague’s treatment plan. He was also mindful that the hospital had recently been involved in a lawsuit concerning a patient’s right to continue therapy despite limited benefits and significant risks. The nurse who was scheduled to administer the chemotherapy conferred with the CNS, expressing her concerns that Edgar did not understand what he was facing. She knew that the high-dose chemotherapy was risky at best and was unlikely to provide much benefit. Although neither the staff nurse nor the CNS knew the patient, they both felt it imperative that someone speak to Edgar and his family about the risks of therapy. The CNS went to Edgar’s room, introduced herself, and spoke of the realities of the current circumstances. Her anguish regarding the need to have such a difficult conversation was reflected in her face and the tears in her eyes. Edgar, his wife, and the nurse held hands as the three of them discussed what Edgar wanted. He elected to go home as soon as possible so that he might spend time with his friends, play a few games of checkers, and be with his family.

The opportunity to immerse one’s self along with the patient in physical, psychological, social, and spiritual realms is rarely offered as frequently in any other nursing discipline. Establishing
articulate personal values. This is an opportunity for nurses to take the lead in care and provide an opportunity for all team members to consider the rationale for care. These discussions serve to articulate personal values. This is an opportunity for nurses to role model moral courage. By continuing to articulate concerns about circumstantial realities versus medical intentions and encouraging an ongoing dialogue with the patient and family, the nurse may facilitate the health care team’s acknowledgment of its impotence and allow patients greater opportunities for a peaceful and dignified death.

Selected Ethical Issues in Palliative Care

Ethical issues in palliative care involve and affect patients and their significant others, health care providers, the health care delivery system, and society as a whole. Issues central to discussion and debate focus on concerns about individual autonomy versus societal norms or the state’s interest; disparity between the patient’s goals of care and those of family, friends, and the health care team; adequacy of communication essential for informed decision-making; consistency of care across the illness continuum; and the allocation of health care resources across the wellness–illness continuum. These broader issues are revealed in disputes regarding the appropriate timing of transition from curative to palliative care, withholding and withdrawing treatment, an individual’s right to use personal value-based parameters (e.g., quality of life, religious beliefs, cultural norms) as the ultimate arbitrator of the value of existence, and the right to assistance in dying.

Death does not seem to visit us “gently.” For many patients and families in the palliative care phase of illness, the simplest of decisions may carry significant consequences. Ethical issues consistently arise as nurses struggle along with patients and their significant others to make realistic yet comforting decisions. Nurses’ obligations to individuals at the end of life reflect a wide spectrum of behaviors. Navigating the health care delivery system, with its myriad professionals and sites of care, can be daunting. Patients and families often lose sight of appropriate goals of therapy when multiple clinicians are involved in the plan of care. Once the nurse is assured of informed consent, appropriate interventions include discussions about personal choice, the goals of medical care, and subsequent choices about that care.

Meaningful conversations cannot occur in the midst of unrelied symptoms. Nurses must advocate for and contribute to effective pain and symptom management. They must become expert practitioners, hold others accountable for that same standard of excellence, and continue to advocate for the patient until symptoms are satisfactorily managed.

Corley identified multiple care scenarios that contribute to nurses’ moral distress. She described circumstances in which terminal ill patients were not allowed to die with dignity, critically ill patients were resuscitated without a clear understanding of their circumstances, patients died with inadequate symptom management, and dying patients were kept on life support until death. Although the specifics of patients’ and families’ wishes regarding care were not identified, what is clear is that nurses experience moral angst about the rightness of their actions.

Nurses must be involved in discussions regarding (1) withholding and withdrawing treatment, (2) providing care demanded by patients but deemed inappropriate by the health care team, (3) patient requests to stop eating or drinking, (4) appropriate criteria for sedation to relieve intractable distress, and (5) patient requests for assisted death. As central providers of palliative care, nurses must serve as a moral voice in these dialogues. In so doing, they are able to honor their commitment to patients and families.

Pain and Symptom Management

Optimal pain and symptom management continues to be a priority and one of the most important ethical issues in palliative care. Patients worry that pain or other symptoms will not be well managed, and they articulate that physical symptoms are far more stressful than the cancer diagnosis itself. Pain, dyspnea, fatigue, nausea, sedation, and confusion are troublesome. These unmanaged symptoms can strip patients of their dignity, impose tremendous professional and ethical burdens on nurses, and destroy the quality of life of both patient and family.

Although all symptoms are deserving of the same meticulous attention, pain continues to be the most prevalent of physical symptoms at the end of life. Overwhelming and unrelied pain can cause anxiety, irritation, restlessness, sleeplessness, depression, fatigue, emotional withdrawal, and existential distress for both patients and caregivers. Its continued presence can provoke patients to request life-ending measures. Unrelied pain is both an emergency and an ethical dilemma and demands the full attention of the palliative care team until resolved. This dilemma can be even more pronounced in the home care setting, where nurses work independently with patients. The standard to which all health care team members must be held is adequate pain relief as defined by the patient.

Case Study

Jonathan, a Man with Progressive Lung Cancer

Jonathan had rapidly progressing lung cancer. He was admitted to the hospital for intensive care secondary to obstruction. The pain management nurse saw him on consultation and
found him to be a man in extreme pain with orders on the chart for nonsteroidal antiinflammatory drugs and “no narcotics.” She determined that Jonathan had been previously discharged on an oral opioid without an accompanying bowel regimen. Three weeks of opioid therapy without any kind of laxative intervention had triggered severe obstipation and ultimately sepsis. Jonathan had been hospitalized for almost 1 month when the pain management consult was written. His physician was reluctant to use opioids for fear of causing the same problem. The nurse discussed the use of opioids in tandem with an aggressive bowel regimen and recommended intravenous opioids immediately, titration to effect, and concurrent titration of an effective bowel regimen.

She spoke to Jonathan, who was frantic for any kind of pain relief, and described what the plan of care would be. As she administered the initial dose of intravenous opioid, tears came into his eyes as he relaxed and allowed the medication to relieve the pain. Over the next few days, the opioid was titrated upward, and a bowel regimen that differed from the norm was instituted. As the nurse prepared Jonathan for discharge, he gave her a napkin on which he had drawn a picture of an angel. “That’s how I see you,” he said. “Thank you for saving me from hell.”

Although aggressive pain management in terminally ill patients rarely causes death, the fear that it will do so continues to be a significant ethical barrier to adequate relief. Many nurses are reluctant to administer the analgesic doses necessary to adequately control pain for fear of causing respiratory depression. The ANA expects nurses to use effective doses of analgesics for the proper management of pain in the dying patient and has stated that increasing titration of medication to achieve adequate symptom control is ethically justified.26 In 1997, the Supreme Court, although disallowing an individual’s right to physician-assisted suicide (PAS), cogently argued that palliative care may and should be aggressive, even if the provision of such care should hasten death.29a

An ethical responsibility of advocacy emerges as the nurse anticipates and plans for expected sequelae to both the illness and any side effects of prescribed analgesics. Discussing expected symptoms, and the plan for managing those symptoms should they occur, relieves patients and caregivers, provides an opportunity to articulate other concerns, and reassures patient and their caregivers that future “unknowns” can be expertly handled. Further advocacy responsibilities include suggesting pharmacological and nonpharmacological interventions to other members of the health care team, consulting with the physician for assistance in managing difficult symptoms or side effects, and continuing to attend to those issues until they are satisfactorily resolved.30

A genuine collaborative approach to palliative care requires the acknowledgment that no one team member has exclusive domain over specific areas of knowledge. In the absence of a communal collaborative milieu, nurses must continue to advocate for the very best in pain and symptom management; they should role-model appropriate analgesic decision-making and should never apologize for what they know.

The use of placebos is less frequent in today’s health care system for the management of cancer pain, but it does still occur. The Oncology Nursing Society (ONS)31 has issued a position paper on cancer pain management stating that placebo use is appropriate only if a patient has provided informed consent. Placebos should not be used to assess or manage cancer pain. Their use is deceitful, is harmful to both patients and health care professionals who use them in a dishonest way, and can damage or destroy the nurse–patient relationship. Nurses, as moral agents, have an ethical responsibility to avoid the use of placebos and to assist in establishing institutional policies to prevent their use in pain management.

Issues of Truth-Telling

Ethically sound communication is central to the highest standards of palliative care. Issues concerning to every domain of quality of life (i.e., physical, psychological, social, and spiritual) require communication such that goals and expectations can be articulated and those who are cared for can know the comfort that a shared experience provides. Ethical principles are reflected not only in behavior but also in language.32

Delivering bad news is an essential part of practice in the palliative care arena, and truth-telling, although viewed as ethically appropriate behavior, can be morally troublesome in a multitude of situations. There is little disagreement in western European cultures that autonomous patients have the right to complete information regarding their illness, potential interventions (including risks and benefits), and prognoses, in order to make informed decisions. However, the ability to function as an “existential advocate”33 is far more complex than the verbalization of correct information. Issues such as presenting truthful information to both asked and unasked questions without destroying hope, providing information that has been purposefully “filtered” because of the patient’s wishes or cultural background, and confronting other members of the health team who obscure information because of their own fears are not uncommon.

Truth-telling should occur in the context of the patient’s wishes and emotional status. The nurse should confirm that the patient is ready to hear difficult news while concurrently giving permission to defer the conversation until greater emotional resources are available or family support is present. When difficult questions are asked, one of the authors responds in this manner: “I need to be sure that when you ask what must be very hard questions you want a truthful answer. I am an honest person and would feel I was honoring you by doing so. However, I want to hear from you how you believe these discussions would best be handled.”

A reasonable ethical standard requires that patients receive answers to difficult and frightening questions as quickly as possible. Although conveying distressing news has historically been the physician’s domain, the multidisciplinary structure of palliative care allows a modification of these role expectations.
in deference to the patient’s best interests. Patients often question nurses regarding test results that could confirm a life-threatening illness or progression of that illness. It has been common practice for the nurse to refer the patient to the physician at such times. But is it appropriate to ask the patient to wait and, of course, worry until the physician arrives? Is it unfair or unkind to postpone for what seems an interminable period answers to questions that carry such grave import? These circumstances offer nurses a unique opportunity. The best possible scenario in such situations would be a rapid resolution of the matter. Table 57–2 summarizes recommendations for a collaborative approach to truth-telling. Appropriate follow-up would include offering to be present when the patient discusses the information with others and leaving the door open to revisit any of the issues raised.

If the physician cannot be reached or a physician unknown to the patient is on call, and the nurse can answer the questions correctly and appropriately, they should be answered. If the nurse has established a close relationship with the patient, it can be argued that it is reasonable to hear difficult news from someone who is known and trusted. Remaining attentive to the primary goal of allowing the patient access to information as quickly and humanely as possible removes the focus from role issues to that of patient interests. However, nurses should not provide information that has not been verified, and they should not feel compelled to answer questions that they are not able to competently address. It is often necessary to provide compassionate understanding of the patient’s anxiety regarding undisclosed information, yet defer to the physician to provide the actual information.

The patient’s wishes regarding access to information about the illness, prognosis, progression of the illness, and plans for care trump everyone else’s wishes. However, it is not uncommon for members of the health care team to present an inaccurate, obscure, or overly hopeful description of the current physiological circumstances; to ask colleagues on the team to remain positive about outcomes regardless of current realities; or to ask that the patient not be told of the current realities. Physicians may write a do-not-resuscitate (DNR) order for a patient, without having a previous discussion with the patient and family, because they are uncomfortable with the topic or believe that the patient and or family may refuse such a request. DNR orders, which have been upheld by the courts, disallow heroic measures (at the request of the patient or family) in a multitude of health care circumstances. DNR orders can serve patients well by preventing unwanted and unnecessary interventions, but they may also be improperly and unethically used to unilaterally prevent life-sustaining treatment. In each of the circumstances described, it is the perceived physician–nurse power differential that may provoke a sense of moral distress and impotence in nurses.

The tactic of using technical or purposely obscure language when breaking bad news to a patient is unethical. Patients may be confused, unsure, and reluctant to ask further questions. Family members become uncertain and anxious as well; they should, with the patient’s permission, be kept current as to the illness, its status, and expected outcomes. If these behaviors are indicative of the professional’s own anxiety and sense of unease, the problem should be openly discussed among members of the multidisciplinary team. Nurses can act as both witness to and translator of the clinical conversation by articulating the inherent lack of understanding that occurs when clinical jargon is used to frame and distance an event.

If other members of the health care team request that the patient not be told, the nurse should ask for the rationale prompting the request. If self-protection or discomfort is evident, it is appropriate to speak to the ethic of truth-telling and offer to assist with the task. These circumstances can be particularly difficult for nurses and require sure knowledge of informed consent, effective advocacy skills, and a genuine sense of the moral weight of truth.

Family or friends may ask that the patient be “protected” from distressing news. A promise to keep silent would interfere with the nurse’s truth-telling ethic and potentially compromise the nurse–patient relationship. The request should, however, prompt a frank discussion with concerned family members in a quiet and protected environment. Family concerns and the adverse consequences of well-meaning attempts

to protect the patient can be addressed. Potential solutions include “checking in” with the patient about the amount of information wanted in the presence of a family member and offering the services of any member of the health care team to assist the family in difficult discussions with the patient.

CASE STUDY
Margaret, a 72-Year-Old Woman with Advanced Breast Cancer

Margaret was 72 years old when she was diagnosed with widespread breast cancer. Her family asked the health care team to avoid the term “cancer,” because, they argued, it would destroy all hope. Despite repeated conversations, the family was adamant that this would be what she wanted. Margaret had not been part of this conversation about what she would want, and the team was uncomfortable about the family’s demands. Her family left to get breakfast, and the physician was writing treatment orders, still deliberating how he might best honor Margaret and her family. The nurse was in Margaret’s room starting an intravenous line. Margaret grabbed the nurse’s hand and said, “I know there’s something terribly wrong. I see those fake smiles and hear those words that don’t make sense. Surely you can tell me what’s wrong with me. I want to know, and I want to know now.” Her grip was tight on the nurse’s hand. The nurse looked into her eyes and replied, “You have breast cancer that has spread to your bones. Your doctor is planning treatment for you right now. I’ll go and get him so you can talk to him.”

An equally complex dilemma arises when the patient’s cultural norms are such that it is inappropriate to discuss diagnosis and prognosis. The ONS describes provision of “culturally appropriate and competent” care as a primary right of cancer patients. Clinicians accustomed to the Western model of informed consent feel unsettled when patients abrogate autonomy to family members. However, asking individuals from culturally diverse groups to express their wishes may seem not only bewildering but also unnecessary, distasteful, or even immoral. Cultural values may dictate that the family receive the frightening information and filter it for the patient. Although it is ethically important to honor cultural dictates, it is equally important to query the patient regarding the extent of information desired. Health care team members can wrongly assume that a patient’s heritage reflects stereotypical behaviors and beliefs. In fact, individual variation is the norm.

Honorin Patients’ Wishes

The SUPPORT study, which examined how and where people died and whether their deaths occurred in line with previously expressed wishes, reflected the gaps in meeting the dictates of the Patient Self-Determination Act (PSDA). The PSDA mandated that health care professionals educate patients about advance directives at the time of hospital admission and document their existence in the medical record. As previously mentioned, advance directives were not common, but a more urgent matter was that physicians routinely did not discuss end-of-life issues, nor did they know patients’ preferences for resuscitative measures.

Informed consent in end-of-life care is imperative for reasons beyond the legal requirement. Patients and families considering refusal of further treatment should be told of the consequences of their choice, just as they are informed of the benefits and risks of other interventions. Patients and families encountering the withdrawal of treatment may not have been fully informed of the risks and benefits of therapy at initiation, nor of the possibility that treatment could be discontinued if no longer beneficial to the patient.

When the burdens of continued treatment are known, patients with decision-making capacity may refuse or stop unwanted medical treatment even if such refusal could result in their deaths. Those who lack capacity have the same rights, but those rights may be exercised through an authorized surrogate decision-maker. This right may be ethically burdensome for nurses if they believe that further intervention would markedly benefit the patient. In these circumstances, nurses are obligated to ensure that the patient is not abandoned, emotionally or otherwise.

The medical, legal, bioethical, and consumer advocacy communities are in agreement that support for and encouragement of individual written directives for healthcare would serve patients well and prevent needless tragedies. The articulation of health care preferences and identification of a surrogate agent to advocate for those preferences can reduce questions and conflicts about what a patient would want, provide direction to the health care team, and relieve family members of the burden of difficult decision-making.

However, a low completion rate of written (advance) directives, as well as their inability to direct care in actual clinical situations, continues to be the norm. Individuals may choose to defer to the health care team for appropriate decision-making, may be reluctant to contemplate the issues at all, may argue that they will complete a written directive when “it is really needed,” or may refuse to commit themselves to a specific course of action. If a written directive is actually available in a time of crisis, the language may be too obscure to direct the course of care, or the choices may be challenged by the patient’s family or members of the health care team.

It is not surprising, then, that a patient’s values and wishes can be compromised in a multitude of ways, both intentional and unintentional. The inability to affirm a patient’s care preferences may occur in situations such as the following: (1) providing care that one believes the patient would want based on knowledge of that individual’s value structure; (2) changing to a pattern of care that one considers appropriate, but that does
not reflect the patient’s wishes, after family members have left the clinical setting; (3) allowing family members to speak for a timid patient who has privately expressed health care choices that are at odds with those of the family; and (4) ignoring known preferences or honoring the preferences of assertive family members when the patient can no longer articulate personal wishes. In all of these instances, nurses have an ethical obligation to speak to the truths that exist and to hold all health care providers accountable to those truths. If necessary, the nurse may refer the case to the institution’s bioethics committee.

**Abandonment**

Meaningful relationships require continued presence. The ability to remain available in the midst of considerable anguish, fear, sorrow, or profound grief requires tremendous courage. Nurses must be willing to set aside personal biographies and professional privilege. If nurses allow professional attitudes to distance themselves from the intimacy of the experience, their role is diminished and the relationships lose meaning. Nurses must be able to function in a partnership with patients, recognizing and acknowledging that one of the most meaningful parts of their response to the dying experience is continued presence.32

Patients fear abandonment in response to decisions that conflict with those of the health care team. The fear of losing those whom one has known and trusted at a time of crisis can be overwhelming. Moreover, abandonment can be very subtle. If a patient or patient advocate chooses a course of care that is disconcerting or unacceptable (i.e., refusing treatment, stopping active treatment, demanding treatment deemed useless by the health care team, or asking for removal of life-prolonging interventions), health care professionals may withdraw in a multitude of ways. Less time may be spent with the patient, or such visits may become less frequent, and direct verbal engagement may become limited. Any of these behaviors may be viewed by the patient and family as emotional withdrawal at the least and abandonment at the worst.

The ethical dilemma is evident: How can one balance one’s own moral values and the patient’s right to autonomous behavior while remaining available to and supportive of the patient? Nurses are particularly vulnerable. They may feel “caught in the middle” if they are expected to provide care in circumstances that clash with their personal values. While wanting to remain loyal to the patient, they may be conflicted by (1) providing care they deem futile or inappropriate—for example, continuing artificial life support despite a diagnosis of brain death; (2) following orders to provide care that is morally unacceptable—for example, discontinuing hydration or nutrition or removing a patient from a ventilator; or (3) responding to requests from patients that they cannot honor—for example, a request for assisted death.23

According to the ANA Code for Nurses,45 nurses may morally refuse to participate in care, but only on the grounds of patient advocacy or moral objection to a specific type of intervention. Although it is ethically imperative to reassure the patient/family unit that their decisions will be respected and they will not be abandoned if their goals differ from those of the health care team, nurses may remove themselves from the patient’s direct care while simultaneously continuing to be available to the patient. These behaviors reflect a continuous partnership and acknowledge the importance of an ongoing personal commitment to caring and problem solving.46

**Case Study**

**Caroline, a 60-Year-Old Woman with Leukemia**

Caroline and her nurse grew to know each other very well over her weeks of treatment for acute myelogenous leukemia. She was hoping to receive a bone marrow transplant (BMT), which she believed would cure her. She was 60 years of age, was becoming increasingly frail, and had limited functional capacity. The health care team had reservations about the advisability of a BMT but did not discuss those reservations with her. The task at hand was to get her into remission and ready for the transplant. One week after discharge and successful completion of the induction therapy, Caroline returned to the hospital with recurrent disease and in significant pain. She asked her nurse if she would die and how it would be. The nurse told her that another course of chemotherapy would be given, that the odds for cure had decreased markedly with the recurrence, and that the BMT posed grave risks to her life. She also described complications that would occur if the cancer did not respond to treatment and how those symptoms would be managed. The leukemia did not respond to reinduction chemotherapy, and Caroline’s pain worsened. In getting out of bed one day, she moved too quickly and suffered a pathological fracture in one of her vertebrae. The pain was severe and not easily managed. It was quiet on the unit early the next evening, and Caroline asked the nurse to sit with her. She seemed so frightened. The nurse sat beside her on the bed and held her hand. Caroline said, “I can’t do this anymore. I’m so tired, and I’m afraid of the pain. Please give me a shot and put me to sleep forever.” The nurse felt anguish at the request, for she had promised Caroline she would not let her suffer. She felt cowardly and disloyal as she explained why she could not provide the medication. Her moral distress centered on her inability to honor her promise and her mixed feelings about what would be appropriate in those circumstances. She promised Caroline she would stay with her and make sure she was comfortable. She asked whether Caroline wanted her to call someone else to be there with her, but she declined. Caroline died that night, never having spoken another word to the nurse.

This case brings attention to multiple issues that might have led to a better outcome for the patient, family, and health care team. Earlier and frank discussions with the patient and family about the course of the illness, the prognosis, and treatment expectations and realities might have allowed both the patient and family the opportunity to plan for death in a more
comprehensive and meaningful way. These discussions might have presented opportunities for understanding the patient’s perspective on assisted death and the circumstances that might trigger such a request. Finally, it would have allowed the health care team an opportunity to be clear about the kind of support they could offer.

**Futility and Withdrawal of Treatment**

Decisions in the clinical arena are increasingly made under a new kind of pressure. With almost every health care delivery institution facing financial constraints, health care providers are experiencing the tensions of “limits” imposed on professional standards of care. A powerful new vocabulary, that of “medical futility,” has entered the discourse.

Health care professionals often feel that patient expectations and desire for care are unreasonable, sometimes impossible, and, on occasion, limitless. Nurses may find themselves searching for unilateral solutions to complex problems when historically they have acted in tandem with the patient and family. They may feel that a patient’s continued treatment serves no purpose, increases the suffering quotient, and uses increasingly scarce resources. They question what good comes from their actions and ask whether these interventions may be refused. Influenced by outcome-based practice standards, reimbursement formulas, and a growing disenchantment with “hi-tech” interventions, these dilemmas evolve into questions of whether to withhold or withdraw treatment.

But it is often precisely at this moment that patients and families insist on continuation of aggressive treatment and question the health care system’s motives, wondering whether the declaration of futility is a cover for cost containment or racial or other prejudice. They feel increasingly alienated from and even abandoned by the health care staff. This dilemma is becoming more common: Is it ever ethical to withdraw care deemed futile by the staff in the face of an intense patient or family desire to continue? A description of the nurse’s role in such circumstances can be constructed only after there is a clearer definition of futility and an understanding of the legal and ethical dictates supporting the clinician’s right to withdraw treatment.

Many definitions of medical futility have been proposed. Some have defined a futile treatment as one that does not serve a valid goal of medical practice (a standard of medical judgment), with it being the normative professional responsibility of the medical team to decide whether desired treatment courses are realistic. Others have argued for a more precise definition, suggesting that a treatment is futile if it is unsuccessful more than 99% of the time (a standard of efficacy). Still others have indicated that treatment outside accepted community standards could be understood as futile (a standard of communal evaluation).

Rubin suggested that futility exists if the treatment does not achieve the patient’s intended goal. As Younger noted early in the debate, futility is a concept that makes no sense standing alone; rather, it is an evaluative judgment based on the worth of possible goals. The value of a treatment would depend on the meaning of the goals and who was empowered to select them, and that same treatment would be futile only if the goals could not be met. With that understanding, the contemporary futility debate could be understood in terms of power: the power to define the acceptable use of medical interventions, to determine whether and under what conditions limits can be appropriately set, and to negotiate the terms of the provider–patient relationship.

The demands of the current health care system ask the health care team to assess a treatment’s relative futility even though there is no agreed definition or determined criterion against which it can be measured. Further, they are asked to develop practice standards and institutional policies even though there is no vision of how to set appropriate limits. Worst of all, they are offered the illusory hope that complex ethical dilemmas can be resolved merely by identifying treatments as futile and concluding that they need not be provided or paid for. Reframing the futility discussion in the language of goals is one of the most effective ways of addressing the moral appeals at stake in conflicts between patients and their providers, and, in the authors’ opinion, it is the most significant intervention clinicians and ethicists can make when the new language of futility emerges as a way of talking about a case.

In the majority of situations in which death is imminent, consensus is reached and life-sustaining interventions are not provided. Conflicts in which questions of relative value arise do not represent straightforward issues of futility. Examples include life-sustaining interventions for a patient who is in a persistent vegetative state, resuscitation efforts for patients with life-threatening illnesses, use of chemotherapy for patients with extensive metastatic cancer, and use of antibiotics or artificial hydration and nutrition for patients who are in the advanced stages of an illness.

The concept of medical futility is more commonly invoked when values conflict. Those arguing from the provider’s perspective believe that the health care team should neither offer nor provide therapy that is unlikely to work or will only diminish quality of life. To do otherwise, they believe, would be to violate professional integrity, offer false hope to patients and families, and inflict harm on patients without the possibility of benefit. Others disagree, wondering why the provider’s values should override the values of the patient and family, especially if those values are religiously based. The disagreements that arise are fundamentally moral and not medical in nature.

When a claim of medical futility arises, the investigation should first identify the goals and intentions of treatment and determine whose goals seem to be taking precedence. This offers a more productive method for discussion of concerns and the mutual exploration of goals and their meaning. It also encourages the health care team to consider their ability and commitment to meet goals that differ from their own. If inadequate communication is part of the problem, assessing and responding to misunderstandings by clarifying diagnosis and prognosis, eliminating medical jargon, discussing what “do everything” actually means, and checking for mistaken notions
of legal requirements can be extremely helpful. Interpersonal issues such as distrust, grief, guilt, intrafamily issues, secondary gains, differences in values, and religious beliefs may contribute to the conflict and should be explored. The nurse, who is more likely to have developed a close relationship with the patient and family, should be involved at every stage of the futility discussion. Opportune moments may arise when other members of the health care team are not available, and that particular nurse–patient conversation may help to resolve the conflict.

The withdrawal or withholding of life-sustaining treatment is very often at the heart of medical futility conflicts. Withholding or withdrawing life-sustaining medical interventions is considered neither homicide nor suicide. Courts have drawn a distinction between purposefully causing a patient’s death and allowing a patient to die after life-sustaining measures are withdrawn. Courts have upheld the validity of DNR and other treatment limitation orders, and there are no limits on the type of treatment that may be withheld or withdrawn. Ventilator withdrawal and the withholding or withdrawing of parenteral nutrition and hydration may occur under the same conditions, as any other form of medical treatment.

That moment in nursing that demands an elegant level of practice is the moment when patients and families decide to forgo aggressive care and elect a palliative approach. Patients and their families may need support for such difficult decisions and often require repetitive feedback about medical data, review of past therapies, reconsideration of any potential interventions, and, in some instances, retrospective permission to make that particular choice. Nurses have witnessed the dilemma of physician withdrawal when the medical team painfully confronts its inability to cure. The turn to palliation is not a defeat for the nurse but, rather, an intensification and revaluing of the skills of nursing. The graceful art of deferring to the patient’s story and remaining emotionally available in the face of considerable fear and anguish involves interaction on multiple intellectual and emotional levels and enriches the lives of both the patient and the nurse. In this context nothing is futile—no touch, no glance, no offer of assistance, and no silence held in common. The worth of the interaction is always based on nurturing and caring as an end goal. It is a stance that will require fierce protection and defense.

Despite legal support for withholding or withdrawing life-sustaining treatment at the patient or proxy’s request, the health care team can find itself at odds with patients and families who become suspicious, fearful, and often unmoving in their opposition when the subject is broached. Ethical differences exist in any pluralistic society, especially one in which resources are increasingly scarce. The desire to struggle aggressively with death is one of the most deeply rooted moral choices an individual can make, and there is little consensus about those choices, as evidenced by the right-to-life and assisted death debates.

Although there are circumstances in which life-sustaining treatment can be stopped over the objections of patients and families—for example, when a patient meets the defined criteria for brain death—consensual standards should be developed after the fullest possible public discussion. Because there is no authoritative legal definition of medical futility or clear resolution in the courts as to its meaning or jurisdiction, the critical voices of physicians, nurses, and patients must be heard. Claims of medical futility cannot be made simply to transfer unwilling patients gratuitously into hospice settings as a cost-saving scheme.

The discussion cannot occur in a piecemeal fashion, at the bedsides of the most vulnerable or in the closed boardrooms of individual institutions. Opening a communal debate rather than closing it with simplistic unilateral solutions is the only defensible decision-making process and the only way out of the futility challenge. Bioethics committees allow for such discourse and, their approach could become the template for (1) discussion of difficult cases, (2) just evaluation of new outcome data, (3) allowing for cultural differences in the selection of goals, and (4) facilitating end-of-life decision-making. This approach would allow for a forum of careful debate before the inevitable crisis emerges, and for an appeals process that would permit a more detailed immersion into the decision-making process. Whenever possible, joint decision-making should occur. If resolution is not forthcoming after careful and deliberate discussion, a step-by-step process of communication and problem-solving has been suggested by the American Medical Association (AMA). See Table 57–3 for a “due process to futility situations” paradigm.

CASE STUDY
Matthew, a 42-Year-Old Man with Recurrent Lymphoma

Matthew was 42 years of age when his aggressive form of lymphoma recurred. He was admitted to the ICU insisting that he wanted everything done and adamant that he meant everything. His wife Sue supported him in that decision, but, as the hours passed and he became increasingly ill, she started to question their decision. Sue spoke at length with the nurse about their personal history. This was her second marriage, her first husband having died of cancer. Matthew had promised Sue that he would never leave her, that he would not die before she did. The nurse spoke at length with Sue, reviewing current interventions and Matthew’s prognosis in relation to those interventions. She asked Sue to review their family’s goals in light of this difficult prognostic information. Sue agonized about having the conversation with Matthew and expressed concern about feelings of guilt and disloyalty. The nurse continued to encourage her, framing the discussion in terms of goals of care, Matthew’s suffering, and the health care team’s commitment to both of them. Sue understood that she would need to give Matthew permission to let go. She could see he was going to die despite the intensive interventions, and she wanted him to have a peaceful death. She did talk with Matthew, and most of the interventions were discontinued after that conversation. The next day, as Sue held him, he died.

Assisted Death

The profound existential issues innate to end-of-life care are no more evident than in discussions regarding assisted death. The adult patient’s right to control health care interventions has historically allowed individuals to refuse to seek medical care, refuse recommended care, stop hydration and nutrition and other prescribed recommendations, and forgo or discontinue life support. These historical methods of ending life sooner have become commonplace. They are legally and also morally acceptable. The ability to exercise autonomy in health care decision-making, as reflected in these circumstances, has engendered questions in both the medical and lay communities as to the “rightness” of extending autonomous behavior to other practices that have been described as humane—interventions that would stop or prevent intractable suffering or unacceptably diminished quality of life. Certainly the courts have supported an individual’s right to refuse or withdraw from life-sustaining treatment.4,37,50,51

It has been argued that withholding or withdrawing treatment and refusing treatment are no different, from a consequential perspective, from PAS, voluntary active euthanasia, or sedation for intractable distress in the dying.55–59 Others have argued that there is a distinct moral difference.60,61 Although PAS is a small part of the process of improving care for all dying patients and their families, the current and intense focus on the quality and scope of end-of-life care has added fuel to the debate about it. Scholars, lawyers, ethicists, health care personnel, religious organizations, and consumer organizations have taken varied stances, as reflected in Table 57–4.61–66

Professional health care organizations such as the AMA, the ANA, and the Hospice and Palliative Nurses Association (HPNA) have published position statements opposing PAS but strongly supporting excellence in end-of-life care. The position of the ONS on nurses’ responsibility to patients requesting assisted suicide67 recognizes that “individual nurses may encounter agonizing clinical situations and experience both personal and professional tension and ambiguity surrounding a patient’s request for assisted suicide.”68 Nurses are urged to explore the rationale for the request, assess and provide for any unmet needs, and resist any behavioral or nonbehavioral indications of abandonment. Schwarz,69 in a phenomenological study, found that few nurses unequivocally agreed or refused to directly help a patient die. Most grappled in solitary and silent ways to find interventions that would be legally and morally acceptable.

Oregon voters approved PAS in 1994, and the appeal process ultimately sent the question to the United States Supreme Court. In June of 1997, the Supreme Court ruled that an individual does not have a Constitutional right to assistance with dying, nor does a physician have an obligation to provide that assistance.29a Subsequent to the Supreme Court decision, in the fall of 1997, the citizens of Oregon again voted and legalized PAS with a 60%/40% majority.69

Terminally ill residents of Oregon are able to receive prescriptions from their physicians for lethal medications that may then be self-administered.69 Criteria to protect citizens from coerced or involuntary action include the following (1) the patient must be an adult able to make and communicate decisions; (2) the terminal illness must be expected to lead to death within 6 months; (3) there must be one written and two oral requests separated by a 2-week period; (4) there must be confirmation of the terminal diagnosis, prognosis, and capability by both the patient’s primary physician and a consultant; and (5) there must be referral to counseling if either the primary physician or the consultant believes that the patient’s judgment is impaired by depression or some other psychiatric disorder. The primary physician is also responsible for discussing all feasible alternatives with the patient—that is, comfort care, hospice care, and pain-control options.

Many reasons have been postulated as to what might instigate a request for PAS. Inadequacy of pain relief,70–72 inadequate recognition and management of depression,73–75 or inadequate management of other symptoms such as dyspnea, intractable nausea, and vomiting or diarrhea are believed to be primary causes. In Oregon,57 the very small number of patient requests were more likely to correlate with strong, vivid personalities characterized by determination and inflexibility; a need to control the timing and manner of death;
and a desire to avoid dependence on others. In the summative
experience with PAS in Oregon, unmanaged symptoms have
not been ranked as primary reasons for PAS requests. This
may reflect advances in pain management in Oregon, which
ranks among the top five states in per capita use of morphine
for medical purposes, and the Oregon statute’s requirement
that the very best in palliative care be provided to this group of
patients. Patients with access to a lethal dose of medication
report that it provides them the freedom and reassurance to
continue living, knowing that they can escape if and when
they choose.

Inadequate physical or psychological care is most fre-
quently postulated by professional caregivers, and researchers
have identified characteristics of those requesting assistance in
dying. However, there are sparse data examining the termi-
nally ill individual’s reason for asking the question in the first
place. An expressed desire for hastened death may not be a
literal request but could rather have multiple meanings and
uses. Coyle and Sculco discovered additional possible ration-
ales for this “cry for help.” They identified such requests as
(1) a way of drawing attention to the individual and his or her
unique needs so that they might be seen and heard; (2) a ges-
ture of altruism, to relieve the family of further burden; or
(3) an attempt to manipulate the family and avoid abandon-
ment. Their research reinforced the need to consider the
request in context of the patient’s lived experience.

The spectrum of professional and lay responses highlights
the intensity of the dilemma. Wolfe and colleagues, in exam-
ining the stability of attitudes regarding PAS and euthanasia
among oncology patients, physicians, and the general public,
found a growing disparity between the public and the medical
profession. As laypersons are becoming more comfortable

<tbody>
<tr>
<td>Liberty interest vs. state’s interest</td>
<td>There is equal protection under the law that allows the right to refuse or withdraw treatment and to commit suicide.</td>
<td>There is constitutional power to override certain rights in order to protect citizens from irrevocable acts.</td>
</tr>
<tr>
<td>Autonomy</td>
<td>Every competent person has the right to make momentous decisions based on personal convictions.</td>
<td>Human beings are the stewards but not the absolute masters of the gift of life.</td>
</tr>
<tr>
<td>Quality of care</td>
<td>Removal of legal bans would enhance the opportunity for excellent end-of-life care for all patients secondary to statutory requirements that the very best in palliative care be provided.</td>
<td>The aim of medicine should be to facilitate a death that is pain free but also a human experience. A good natural death contributes value to the community.</td>
</tr>
<tr>
<td>Nonmaleficence</td>
<td>From the patient’s perspective, there is no difference between ending life by providing a lethal prescription and by stopping treatment that prolongs life.</td>
<td>The role of the nurse has been to promote, preserve, and protect human life. Assisted death violates the oath to “do no harm” and destroys trust between the patient and nurse.</td>
</tr>
<tr>
<td>Beneficence</td>
<td>More patients could benefit from relief that is now available illegally to many people who have strong relationships with physicians willing to risk assisting them to die.</td>
<td>A misdiagnosis of the illness, inadequate assessment of competence, or pressure from the family or the physician might place patients in jeopardy.</td>
</tr>
<tr>
<td>Slippery slope</td>
<td>The states could adopt regulations to ensure informed, competent, and freely made decisions.</td>
<td>Although assisted death might initially be restricted to competent, terminally ill patients, in time many other kinds of patients might be assisted to die in more aggressive ways.</td>

with the concept, physicians are growing less supportive. In 2002, Emanuel\textsuperscript{44} reviewed data from surveys of the general public and health care professionals as to attitudes about and experience with PAS and euthanasia. Public support for PAS varied from 34% to 65% and that percentage had not changed over the past several years. Most physicians do not view PAS as ethical, although some have agreed that in some instances suicide may be a rational act. They have consistently indicated that they do not wish to participate in assisted death. There has been a decline in support for PAS on the part of U.S. oncologists that may be due to a more recent focus on end-of-life care and its possibilities. Many studies indicate that a small proportion of U.S. physicians have performed PAS. Requests more frequently come to oncologists, and oncologists generally report having performed PAS more frequently. Of interest is that when physicians encounter such requests, they are very likely to use fewer life-prolonging therapies and to increase interventions aimed at symptom management (e.g., improved analgesic therapy, treatment of depression and anxiety, referral for psychiatric evaluation). Surveys demonstrate that about half of nonphysician health professionals support PAS in some circumstance, but fewer than one third have received requests. Emanuel also reviewed attitudes and practices of U.S. patients. He drew four major conclusions from the data: (1) patients with cancer primarily use PAS; (2) pain does not seem to be a major determinant of interest in or use of PAS; (3) depression, hopelessness, and general psychological distress are consistently associated with interest in PAS; and (4) among terminally ill patients, the extent of caregiving needs was associated with interest in PAS.

In the midst of the ongoing deliberation, nurses daily face ethical dilemmas as to the most appropriate response to patients who ask for such assistance. Matzo and Emanuel,\textsuperscript{85} in their survey of oncology nurses, reported that 30% of the respondents (131 nurses) had been asked to assist with a patient's suicide. Historically, nursing surveys have reflected the professional individual’s ambiguity about this issue.\textsuperscript{30,36} Schwarz\textsuperscript{29} and Volker\textsuperscript{48} described feelings of conflict, guilt, and moral distress in these circumstances. They saw compelling cases in which patients were devastated physically and emotionally by illness and confronted with the suffering and exhaustion of their families. Personal and professional tension and ambiguity about what is right are bound to occur in such situations. At times, it may be difficult to balance facilitation of a dignified death with preservation of life;\textsuperscript{79} and the willingness to consider participation in assisted suicide may be motivated by mercy, compassion, promotion of autonomy, and quality-of-life considerations.\textsuperscript{84,85} Dr. Ira Byock, who has publicly spoken out in opposition to PAS, suggests that our responsibilities, if PAS were legalized, would be to stand by the patient and family, whatever their decision, and continue to provide care. Byock also asserts that although patient choices may differ from the provider’s preference, there is an obligation to respect those choices and struggle along with them.\textsuperscript{87}

Nurses who are asked about PAS or asked to assist with a patient’s suicide are ethically bound to (1) respond nonjudgmentally to requests; (2) provide all relevant information about the state’s legal restrictions as well as alternative treatments and options; (3) participate with the multidisciplinary team in a thorough evaluation of the patient’s rationale for the request; (4) assist in the clarification of goals; and (5) ensure that all symptoms, including depression, are assessed and managed at a level acceptable to the patient and family. Ongoing emotional support and caring for the patient and family can be offered without regard for statutory law.

The Oregon Nurses Association (ONA) has published a white paper\textsuperscript{86} on the Oregon Death with Dignity Act\textsuperscript{69} that supports the ethical stances of nurses who choose to care for or discontinue involvement in the care of individuals who request PAS. The ONA supports both the patient’s right to self-determination and the nurse’s right to a professional practice congruent with personal moral values. Oregon nurses who choose to continue caring for a patient requesting assisted suicide may (1) explain the law as it currently exists; (2) discuss and explore options with the patient and make referrals if appropriate; (3) explore reasons for the patient’s request, ensuring that depression is thoroughly evaluated and treated if present; (4) maintain patient and family confidentiality; (5) provide care and comfort throughout the dying process; (6) remain present during the patient’s self-administration of the medication and subsequent death to console and counsel the family; (7) continue to provide ongoing emotional support; and (8) be involved in policy development within the health care facility or the community. The state expects nurses to respect patient confidentiality and to respect patient choices. Nurses may not inject or administer the medication that will lead to the end of the patient’s life, and they may not make unwarranted judgmental comments to other members of the health care team who care for patients who have chosen assisted suicide.

Ethical imperatives for those Oregon nurses who choose not to be involved can offer some guidance for nurses whose legal jurisdiction does not legitimize assisted suicide and who want to respond appropriately and compassionately to the patients they serve. The nurse who feels ethically compromised in caring for a patient who has chosen assisted suicide is obliged (1) to provide for the patient’s comfort and safety, (2) to withdraw only if assured that alternative sources of end-of-life care are available to the patient, and (3) to continue to provide ongoing care if unable to transfer that care to another provider. Nurses may not breach confidentiality, subject patients or their peers to judgmental remarks about PAS, or abandon or refuse to provide comfort and safety measures to the patient.

The imperative to explore the rationale for patient’s requests needs to be translated into health care policies. Most health care systems do not provide written guidelines for their staff. The Hospice of Boulder County in Boulder, Colorado, has developed guidelines for caring for the patient who expresses interest in hastening death.\textsuperscript{89} Modeled after the ONA’s white paper, it provides a thoughtful and caring structure for a multi-disciplinary response to a distressed patient. Table 57-5 presents a paradigm of this policy.
Ethical Considerations

**Case Study**

**Josephine, a Patient Seeking to Hasten Death**

Josephine was a strong woman. She had emigrated to the United States as a child. When diagnosed with metastatic colorectal cancer, she stoically began treatment. As she and her nurse developed a relationship over time, she mentioned her fears of dependency, of losing her ability to think and communicate clearly, of losing her ability to control her bodily functions. She was absolutely clear that she did not want to die having lost control of her physical or mental abilities. One day she asked her nurse if she would be able to “put her to sleep” when the time seemed appropriate. As the nurse explained why this was not possible, Josephine interrupted her and said, “They treat dogs better than they do human beings.” The topic came up frequently over the next few

<tbody>
<tr>
<td>Identifying Vulnerability Factors and Responding to Those Patients Who Express Interest in Hastening Death</td>
</tr>
</tbody>
</table>

**I. Assessment**

**A. Patient interview**

1. What is happening now that makes you consider this action?
2. If we could relieve that problem, would you still be interested in dying now?
3. Have you thought about a method?
4. What do you know about the consequences of this method for your family?
5. Is this an idea that is yours alone, or has someone suggested that you consider this?
6. Have you discussed this with family members, your doctor, or others who are caring for you?

**B. Evaluation**

1. Satisfaction with pain and symptom management?
2. Depression? Anxiety?
3. Fears? Anger? Family pressures?
4. Personal and spiritual philosophy?
5. History of depression or mental illness?
6. Weapons on the premises?

**II. Intervention**

**A. Team meeting**

1. Physician notification
2. Possible request for ethics committee consultation

**B. Response to unmet needs**

1. Aggressive efforts made to alleviate any unmet physical, emotional, or spiritual needs
2. Anxiety or depression? Offer pharmacological treatment and/or psychotherapy

**C. Response to request**

1. Description of current state law, its requisites, and the provider’s rights and responsibilities
2. Information and counseling regarding the patient’s request
3. Encouragement to discuss with family and others involved in care
4. Removal of weapons from the premises if they present a threat to staff or family
5. Notification of appropriate authorities if violent death (e.g., shooting) occurs

**D. Staffing**

1. Staff assignments made in terms of comfort/discomfort with patient request
2. Support offered to those who have cared for the patient but choose not to continue after a wish for hastened death has been expressed
3. Review of case by involved staff and volunteers

**E. Documentation**

1. Assessment
2. Interventions

*Source: Adapted from Hospice of Boulder County Ethics Committee (1999), reference 91, and Oregon Nurses Association (1995), reference 90.*
months, and each time the nurse reiterated the difficulties while continuing to remind Josephine that she would be supported with the very best in palliative care in order to ensure a death that was peaceful. Josephine never stopped asking for assistance in dying. She ultimately became very confused in her final days. The nurse was with her when she died, and her last words, jumbled though they were, included the word “dog.”

Josephine’s experience reflects the conflicts that nurses encounter daily. Many patients express fears as they near the end of life, such as fear of losing control, fear of acting in a way that they regard as undignified, or fear of living beyond the time they consider acceptable. These fears may be at the most existential and intimate of levels and cannot be dismissed with easy answers. And so patients often ask for assistance in dying. The dilemma for the nurse and other members of the multidisciplinary team is how best to resolve the patient’s deeply felt fears, how best to identify interventions that have meaning, and how to personally resolve the tensions generated by the inability to respond to another’s plea for help. Josephine might have benefited from more detailed discussions of how she could be supported at the end of life and more assistance from the hospice team’s social worker in exploring her fears.

Voluntarily stopping eating and drinking (VSED) has been suggested as an acceptable moral alternative to PAS.90 Although VSED is legally permissible, some patients, families, and members of the health care team may consider this method equivalent to “dehydrating” or “starving” a patient and therefore morally offensive. Ganzini and associates91 surveyed hospice nurses in Oregon regarding their experiences with patients who chose VSED; 33% of the 307 nurses who returned the questionnaire reported that in the previous 4 years they had cared for a patient who deliberately hastened death by voluntary refusal of food and fluids. Nurses reported that patients chose VSED because they were ready to die, saw continued existence as pointless, and considered their quality of life poor. This choice requires considerable patient resolve, because life may continue for weeks; Ganzini’s survey showed that 85% of patients died within 15 days after stopping food and fluids. On a scale from 0 (a very bad death) to 9 (a very good death), the median score for the quality of these deaths, as rated by the nurses, was 8. Should a patient choose this course of action, the nurse should continue meticulous comfort care and may need to implement sedative orders for the management of delirium. The choice to use VSED is based on the patient’s values, and it would be egregious if the physician or nurse condemned the patient for this choice. Those health care professionals who believe VSED to be morally impermissible may excuse themselves from care after ensuring a suitable substitute caregiver.

Even with state-of-the-art care, a small number of dying patients will experience suffering that cannot be satisfactorily relieved—such as pain, shortness of breath, intractable nausea or vomiting, and delirium. “Terminal sedation” as a solution to these unmanageable kinds of suffering is a phrase that has appeared in the palliative care literature in the last few years. The U.S. Supreme Court29a made terminal sedation legally acceptable in the same opinion that ruled PAS was neither a patient right nor a medical obligation.

However, consensus had not been reached as to a clear definition of terminal sedation.92 Chater and colleagues93 suggested the following: “The intention of deliberately inducing and maintaining deep sleep, but not deliberately causing death in specific circumstances[—that is,] for the relief of one or more intractable symptoms when all other possible interventions have failed and the patient is perceived to be close to death and/or for the relief of profound anguish (possibly spiritual) that is not amenable to spiritual, psychological or other intervention and the patient is perceived to be close to death” (p. 257). They also suggested a less pejorative term: “sedation for intractable distress in the dying.”

Regardless of the terminology, there continues to be much debate in the bioethical and medical communities about the moral repercussions of sedation for intractable distress.57–59,76,93 Some have argued that death with sedation for intractable distress is “foreseen” but not “intended,” thereby invoking the principle of double effect—that is, the sedation itself is not causing death but is intended to relieve suffering, an accepted aim of medicine.59,94 Those who take the middle ground allow the possibility that in some cases sedation for intractable distress may be morally acceptable if symptoms cannot be managed otherwise.56,93,95,96 Finally, others see it as tantamount to euthanasia, because the sedated patient may die from the combination of two intentional acts—the induction of stupor or unconsciousness and the withholding of food and water.97 The ANA26 has stated that the risk of hastening death through treatments aimed at alleviating suffering or controlling symptoms is ethically acceptable.

If sedation for intractable distress is evaluated to be necessary in light of current patient circumstances, the health care team must ensure that the patient’s decision is informed and voluntary before initiating the intervention. If the patient lacks decision-making capacity and appears to be suffering intolerably, it is essential to discuss with family members or the health care proxy the exhaustion of all other palliative care interventions and to collaboratively determine the current goals of care in relation to the patient’s health status.

**CASE STUDY**

**Frank, a Man with Intractable Pain**

Frank was an older gentleman with widely metastatic colon cancer. Pain became the formidable adversary of the hospice team. Every possible analgesic intervention was tried, including all atypical analgesics, all anesthetic procedures, including intraspinal analgesia. He continued to experience severe pain and begged to have his life ended. After an emotional but carefully thought out discussion and consultation with the hospital’s bioethics committee, the family supported the
decision to begin intravenous sedating therapy in order to ensure Frank’s comfort. Many of the nurses who had been caring for him believed that this was equivalent to euthanasia and asked to be excused from caring for him. They were forbidden to voice their concerns to Frank and his family but were allowed to offer comforting words and expressions of their feelings for Frank. Those nurses who were morally comfortable with the decision took responsibility for his care.

Ultimately, safeguards must be in place when considering any intervention that might end the patient’s life sooner than would be otherwise true. Such safeguards include (1) informed and voluntary consent after detailed discussion, (2) diagnostic and prognostic clarity, (3) an independent second opinion from a consultant with expertise in palliative care, (4) a brief waiting period and reevaluation of the issues with the patient and family, and (5) documentation and review to ensure accountability.

If the goal of care is to manage a symptom, not to hasten death, documentation of the whole process should be meticulous. The goals of care and discussion with the patient and family (i.e., informed consent) should be clearly outlined in the progress notes. Careful documentation is not limited to sedation to relieve intractable distress in the dying. Withholding or withdrawal of treatment and increasing doses of medication for symptom relief that may secondarily shorten life (e.g., opioids for pain relief) must receive the same careful attention.

**Allocation of Resources**

As health care costs rise, increasing numbers of individuals are without health care insurance, and Medicare reimbursement for older adults changes, questions arise about adequate care for persons at the end of life. Long-term chronic disease has emerged as the primary pathway to dying, representing a prolonged course of increasing disability and illness before death. The financing of end-of-life care largely occurs within Medicare. Of the 2.3 million Americans who died in 1997, roughly 86% were Medicare beneficiaries. End-of-life care represents about 27% of the Medicare budget.37

Providers and patients are concerned about care choices and limitations on those choices. Access to care, the site of care, the philosophical approach to care, and the quality of the care provided are troubling issues. Health care researchers have continued to provide valuable information about where people die. Wennberg and coworkers98 examined the use of health care resources during the last 6 months of life by patients of 77 U.S. hospitals with strong reputations for high-quality care in managing chronic illness. They found that ICU days ranged from 1.6 to 9.5; hospitals days, from 9 to 27; the number of physician visits, ranged from 17 to 76, with 17% to 58% of patients seeing 10 or more physicians; and hospice enrollment varied from 11% to 44% (median, 22% to 32%). Although these data represent a striking variation in the utilization of end-of-life care among those institutions studied, it is a reminder, as was documented in the SUPPORT study,14 that hospice care is not the normative choice for care in the final days of life.

Bird and colleagues99 reviewed a random sample of Medicare beneficiaries who died between 1993 and 1998. Medicare expenditures in the last year of life were lowest for decedents in the oldest age group but 70% higher for those in the youngest age group (ages 65 through 69 years). Inpatient expenditures, regardless of age cohort, represented the largest single cost percentage among sites of care.

Cassel and associates100 examined end-of-life care in ICUs and found that surgeons and intensivists approached care very differently. The former prioritized defeating death as a primary goal, whereas the latter incorporated scarce resources and quality of life as significant variables in the decision-making process. Pekmezaris and coworkers101 examined the specificity of advance directives in relation to site of death and found that a significantly higher proportion of patients died in nursing homes, as opposed to hospitals, if their advance directives specifically prohibited resuscitation, intubation, artificial feeding and hydration, or hospitalization.

Based on data about where people die, it may be argued that our society’s philosophical approach to dying remains grounded in the Western medical model of cure. Selwyn and Forstein102 described the false dichotomy of curative versus palliative care for patients with late-stage HIV/AIDS. Uncertainties about prognosis and the promise and limitations of rapidly evolving therapies have made decision-making about end-of-life issues more complex. As a result, individuals continue on antiretroviral therapy with its significant side effect burden and in the presence of worsening disease, with the hope that they will improve. Fried and Bradley103 examined the influences on end-of-life treatment choices in older, seriously ill persons. They found three major influences: treatment burden, treatment outcome, and the likelihood of the outcome. As might be expected, the burden of treatment was bearable if the outcome was desirable, but individuals were less willing to undergo the burden of care for more marginal results. Of interest was a third finding: some participants disclosed that their willingness to tolerate adverse outcomes might increase even as their illness progressed. Although many observers have believed that cancer chemotherapy is overused at the end of life, Emanuel and colleagues104 were able to confirm this belief. The charts of all Medicare patients who died of cancer in Massachusetts and 5% of Medicare cancer decedents in California in 1966 were examined. Chemotherapy was used frequently in the last 3 months of life, and the cancer’s responsiveness to chemotherapy did not seem to influence whether dying patients received chemotherapy during that time.

The high prevalence of death among ICU patients and readmissions to the ICU generate significant cost expenditures.105 At times of crisis, it is not uncommon for family members to be asked to determine goals of care and to interpret a
patient’s health care wishes. High levels of stress, complex information, inadequate time, and lack of consistent communication do not adequately prepare families to make such decisions. Ahrens and associates\textsuperscript{106} studied the effect of improved communication with family members on length of stay and resource utilization in the ICU. For patients at high risk of death, these researchers compared the length of stay and cost effects of daily family communication by one medical doctor–clinical nurse specialist (MD-CNS) team to the usual communication process. Daily communication in the intervention group focused on daily goals, a discussion of options other than curative care, opportunity to clarify issues, and time to verbalize any thoughts, values, or emotions family members were having. The research team discovered that when families had consistent communication with the MD-CNS team, direct and indirect costs were significantly lower and mortality in the ICU setting was 20\% less, compared with the control group. Length of stay in the hospital and in the ICU were significantly lower in the intervention group. This effort demonstrated that appropriate communication that is medically and ethically sound not only represents excellence in care but has a secondary effect of conserving resources.

Many members of the professional and lay communities have expressed grave concerns regarding the impact of managed care on quality care at the end of life. Slutsman and associates\textsuperscript{107} compared the experiences of terminally ill patients in managed care and in fee-for-service care. Overall, the two populations had to find comparable outcomes. Managed care patients were more likely to use an inconvenient hospital but less likely to have unmet care needs for nursing care or homemaking. There were three primary findings of note: (1) access to care was comparable, (2) there were few differences in the quality of the doctor–patient relationship, and (3) experiences as gauged by specific outcome measures were comparable. McCarthy and colleagues\textsuperscript{108} reviewed the care of 260,000 Medicare patients in the same two populations. Her team concluded that Medicare beneficiaries enrolled in managed care had consistently higher rates of hospice use and significantly longer hospice stays than those enrolled in fee-for-service systems. Although these differences may reflect patient preferences, there is the possibility that some managed care plans are more successful at facilitating and encouraging hospice use for patients dying with cancer.

Nurses must be vigilant in ensuring access to care for patient who are poor, socially disadvantaged, or marginalized by race, ethnicity, language, or geography. The future of quality health care is uncertain, and nurses are ethically obligated to speak for those who cannot or do not speak for themselves.

\textbf{The Role of the Nurse in a Bioethical Community}

The struggles that surround the level and intensity of treatment are not the only ethical conflicts that emerge in the practice of palliative care. Choices about confidentiality, consent, research dilemmas, and family authority create a series of moral crossroads for the nursing staff. When faced with a conflict of deeply held moral values, the nurse must first consider her or his own role in the clinical setting. Then a thoughtful conversation must begin within the “community” that includes the patient, the family (if the patient so desires), and the entire interdisciplinary health care team. It is at this point that institutions have turned to bioethics committees for the “moral architecture” of the clinical conversation.

As an integral part of the interdisciplinary team, nurses must sit at this table to provide descriptive, specific, and personal perspectives on moral issues; advocate for the patient and family; and immerse themselves in the milieu of accountability. A substantive discussion cannot occur without the clear and courageous voice of the bedside caregiver. Nurses must consider what is at stake in the nurse–patient relationship and the obligations of the role. They must evaluate how their own acts will shape both their characters and future practice. Finally, they must be vigilant for moral breaches in care and refer patients and their circumstances to the bioethics committee if a moral conflict cannot be resolved.

The nurse who is committed to palliative care needs to become comfortable addressing the bioethics committee with his or her concerns and involving the ethicist and committee in troublesome cases. The nurse must have the courage to speak of difficult issues, involve patients and families in the discussions, and develop both the patience and the perspective necessary to genuinely hear all voices.

If there is not yet a committee at the institution (hospital, hospice, or home care agency), nurses should (1) be part of the endeavor to create a committee; (2) identify and recommend other health care providers and consumer and public members for membership; (3) advocate for training in bioethics provided by a qualified ethicist; (4) participate in the training and education; (5) assist in establishing a methodology for consistent, ongoing development and education for committee members, other health care providers, and the institution’s lay members; (6) assist in formulating policies regarding treatment issues (e.g., consent for treatment, treatment refusal, withholding and withdrawing of care, withholding nutrition and hydration, requests for assisted death); and (7) assist in formulating policies for education, case consultation, and documentation of the committee’s work.\textsuperscript{109} Nurses can assist in teaching the health care community about ethical norms and controversies, particularly drawing attention to end-of-life dilemmas.

If conflicts emerge and the patient–family–health care provider triad cannot reach consensus, the bioethics committee first assesses the patient’s medical condition and wishes regarding medical intervention. They explore who the patient was before the illness and who the patient currently is, as well as the patient’s current circumstances and situation. This “photograph” of the patient allows for a discussion based on the realities of personhood as well as medical facts and allows the nurse an opportunity to provide details that might not be known by other members of the health care team. The nurse
must also consider the duties of the nursing profession, including resistance to immoral actions or rules, and assess how the decisions made affect the patient’s rights and responsibilities.

Next, the consequences of possible choices are considered. Can harms and wrongs be minimized and happiness maximized? After all the information has been gathered from every possible source, the committee makes a recommendation about the dilemma (Figure 57–1).

As a contributing member of the bioethical community, the nurse will increasingly need to balance autonomy with the issue of justice in the clinical setting, and that will be a challenge. Patients who might reasonably be considered candidates for palliative care may insist on active, aggressive medical intervention. Patients enrolled in hospice programs may demand interventions that would better serve the acute care population. The clinical setting must be a place not only of healing but of fairness, a fact that nurses understand and can articulate.

**Inherent Tensions in Meaning, Power, and Moral Agency**

Attention to ethical and spiritual issues, as well as issues of justice, allocation, and marketplace real politik, shapes the framing of cultural responses to the dying process. In a world focused on productivity, illness and death are viewed as distractions and profoundly personal problems. Limits on nurses’ obligations to the dying are formulated within a milieu of legal and fiscal considerations in which health care and illness are viewed as "business." As Congress debates legislation about how to adjudicate treatment constraints, small battles are being waged at the bedside of the dying every day.

As mentioned earlier, nurses find themselves all too often “in the middle” when there are conflicts between providers, patients, and families about the most appropriate kind of care that should be delivered. Inherent in these tensions are actual ethical dilemmas that nurses encounter daily—circumstances in which two competing moral appeals are in conflict. A classic example might be that of struggling to ensure informed consent when a family does not want to understand current realities and believes that information sharing will destroy the patient’s hope and cause the patient to “give up” (dilemma of veracity vs. maleficence).

Moreover, individual ethical dilemmas occur when the practitioner’s personal values are compromised. As each individual filters circumstantial realities through her or his own “mesh” of values, conflicts arise that may be particular to that person. Clinical issues of withdrawing treatment or providing sedation to relieve intractable distress in the dying can be morally impermissible to some but morally permissible to others. These dilemmas are distinct from legal constraints, fiscal considerations, and cultural implications. Practitioners will continue to struggle as they balance the demands of professional obligation and personal meaning and wonder whether their roles as moral agents will be defended or defeated.

---

Considerations Regarding the Future Role of Nursing in End-of-Life Care

The responsibilities of the nurse in the future will include not only advocacy for patients but advocacy for the staff and team that support the patient. Discussion of advance directives, to be effective, needs to begin much earlier and should be a comprehensive part of the provider relationship—an admittedly difficult task in a changing health care environment. None of what any ethicist can suggest is revolutionary but rather focuses attention on oft-repeated truths. Advance conversations (not just “directives”) about dying and the use of the hospice model merit particular attention.

First, in thinking about advance conversations and end-of-life planning, the professional must incorporate the constellation of friends and colleagues who support the patient. The notion that one is not alone, that one has comradeship and friendship, is embedded in advance conversations. Second, social support for this stage of life must be secured from health care systems that have the ability to provide real options for the dying patient. Nurses must speak strongly and courageously about the need for and value of palliative care to both policy makers and the public. Third, the meaning of the well self versus illness, autonomy versus limits, the importance of control versus the impotence of treatment interventions, the meaning of risk versus the potential for harm, and the place of faith need to be understood by providers before a rigorous discussion with the patient can occur. Nurses, because of their ongoing contact with patients at the end of life, are well positioned to understand the nature of these discussions and to insist on these conversational “gold standards.”

The second critical issue in the future will be support for hospice and palliative care. Pioneering efforts by a multitude of practitioners and support from multiple segments of the public and private sectors are allowing robust consideration of a variety of ways to create innovations in care of the dying. The hospice and palliative care movement frames ethical reflections on the dying process. Hospice interrupts death as an unrelenting, fast-moving tragedy and slows the process with friendship, the claims of even the stranger, and a responsive community.

Hospice care resonates with the name itself—way stations for ones who wandered in war, far from family, moving into a wider and unknown world. Modernity necessitates the same passages. It will be the privilege of the nurse to hear the stories that travelers bring and to recognize the importance of each, even the abandoned, as we collectively work to expand the hospice model. Taking on the care of the dying is an extraordinary responsibility, one that calls on the development of a vision of a life of virtue, of serious personal consideration of what obligations the nurse will take on, and of a turn from the objective to the subjective. For such work, nurses will need to resist strong pressures to rescue and fix what cannot be repaired. They will need to learn to turn from the role of hero to the role of witness.

All of this will require a new sort of language, in a population that is fearful of death they find difficult to master. The speech is ordinary and very plain. It is tempting to pretend otherwise and to discuss problems not in terms of befal lenness, need, and loss, but in technological detail, the mother tongue of medicine. Not only patients and families but also nurses will need to create internal communities of meaning and conversation. Such moral communities are the place for ethical reflection, conflict debate, closer examination of deep moral discord, and, finally, the development of new ethical visions that enrich the lives of all who participate in the experience.

Public Policy and End-of-Life Care: The Nurse’s Role

The public expects nurses to be vigilant in care when they are ill and advocate on their behalf when public policy changes are necessary to promote health. As nurses we are both the professional voice and the voice of the public. We understand the public policy barriers to excellent end-of-life care as we care for others and we understand the barriers as we and our loved ones need care. Because of our unique knowledge, we have a responsibility to inform our communities and policy makers about the possibilities for excellent end-of-life care and identify the barriers to that care. United through our professional organizations we are a powerful voice. We are knowledgeable of both the science of excellent end-of-life care and of the narratives of suffering and healing. Our covenant with the public requires that we speak.—Sylvia McSkimming, PhD, RN, Executive Director, Supportive Care of Dying: A Coalition for Compassionate Care

- Key Points
- Public policy decisions have the potential to positively impact the quality and availability of palliative care services.
- End-of-life care issues have moved to a prominent place on national and state policy agendas.
- Public policy initiatives create a unique opportunity for nurses to influence present and future directions in palliative care.

The convergence of significant trends in clinical, research, social, legal, professional, economic, and political realities has dramatically influenced the evolution of palliative care within the last several decades. It has become clear that end-of-life care is not just the concern of health care professionals, patients, and families. It is also a concern for the public at large and for governmental entities. There has been increasing interest and activity within the public policy arena at the state and federal levels of government that can create needed improvements in end-of-life care. Institutions and individuals also have a responsibility to inform and influence pertinent public policy initiatives. Nurses, as the largest group of health professionals and with a rich history of concern and care for others, have a vital role in advocating for quality of life, particularly at life’s end.

The Evolution of Palliative Care

The enormous strides in research, prevention, detection, and treatment of disease have been incredibly promising. Scientific and medical progress has created significant options and desired choices for those facing life-threatening illness, yet these possibilities have also created poignant questions and dilemmas for those at life’s end, their families, and health care providers. This reality has drawn the attention and activism of health care professionals, the public, and policy makers.

Although significant changes in health care, including end-of-life care, have occurred, and although these have been mostly positive, it is recognized that there is still a dramatic need for additional improvements. Intersecting trends have propelled palliative care to the forefront of American culture.
Changing Nature of Death and Dying

Significant scientific and technological advances have created the possibility of extending life and delaying death. At times, the desire to preserve life has overshadowed the obligation to provide appropriate, compassionate, and dignified care.1 With the expansion of technology, there has been growing attention to the acceptability of limiting treatment interventions and focusing on the comprehensive, holistic needs of the person with life-threatening illness. Recent decades have witnessed the affirmation of the decisional authority of the individual, the dominance of self-determination, the acceptability of do-not-resuscitate (DNR) decisions, the use of advance directives, and the acceptance of withdrawal of life-sustaining therapies.

Judicial Decisions

End-of-life care has also been on the nation’s judicial agendas. Judicial history is filled with cases, court decisions, and opinions that have influenced directly and indirectly the course of end-of-life care. From the middle of the 1970s, starting with the Karen Ann Quinlan case, through the 1997 United States Supreme Court decision;3 the judicial system has dealt with complex issues in end-of-life care, including decisional authority, refusal of therapy, and physician-assisted suicide (PAS). Although each of these decisions dealt with discrete legal questions, these and other judicial cases drew notable attention to the broader questions and concerns in end-of-life care.

Research Data

The acquisition of quantitative and qualitative research data has influenced care at life’s end and has the potential to shape public policy. Multiple clinical, attitudinal, experiential, and health professional studies have been generated in the last several decades. In addition, public opinion polls and surveys have drawn attention to the challenges in providing quality end-of-life care. Although these projects may generate important information, the ongoing challenge is to ensure that relevant data and knowledge garnered from research is integrated into care improvements that benefit individuals and communities. Research data on quality, cost, access, and utilization are necessary for public policy debate and action on needed reforms in end-of-life care.6

The Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatment (SUPPORT) was the largest research project to examine end-of-life care and identify its inherent challenges and deficiencies.7 SUPPORT was a 10-year project divided into two phases: the first phase focused on assessment of the experience of patients at the end of life, including decision-making and clinical outcomes, and the second phase involved testing of an intervention designed to improve communication and decision-making among patients, families, and physicians. Despite attempts to positively affect clinical outcomes, the conclusions of the study found the interventions to be ineffective in (1) ensuring that patient preferences were known and honored; (2) affecting the incidence and timing of DNR orders; (3) decreasing days in the intensive care unit or on a ventilator before death; (4) improving pain management; and (5) controlling the utilization of hospital resources.4

Since the SUPPORT study, numerous other investigational efforts have been initiated. A 2-year comprehensive study conducted by the Institute of Medicine (IOM) concluded that there were serious problems in end-of-life care and delineated steps to address this reality and improve care.8 One of the committee’s tasks was to propose steps that state and federal policy makers and others could take to improve the organization, delivery, financing, and quality of care for persons with terminal illness. An outcome of the study was seven recommendations that could lead to significant improvements and provide a framework for public policy options (Table 58–1).

Also in the late 1990s, the Robert Wood Johnson Foundation, through the Last Acts project, promulgated a set of guiding principles, the “Precepts of Palliative Care,” in an effort to explicate the nonnegotiables of palliative care for the professional community and the public.9 The precepts have been endorsed by numerous national and local organizations and disseminated widely to the public. One precept states that “palliative care relies on the formulation of responsible policies and regulation by institutions and by state and federal governments.”9 The precepts also provide a starting point for needed reform in end-of-life care (Table 58–2).

| Table 58–1 |
| Institute of Medicine Recommendations for Improving End-of-Life Care |

- Create and facilitate patient and family expectations for reliable, skillful, and supportive care.
- Ask health care professionals to commit themselves to improving care for dying patients and to using existing knowledge effectively to prevent and relieve pain and other symptoms.
- Address deficiencies in the health care system through improved methods for measuring quality, tools for accountability by providers, revised financing systems to encourage better coordination of care, and reformed drug-prescribing laws.
- Develop medical education to ensure that practitioners have the relevant attitudes, knowledge, and skills to provide excellent care for dying patients.
- Make palliative care a defined area of expertise, education, and research.
- Pursue public discussion about the modern experience of dying patients and families and community obligations to those nearing death.

(continued)
Several years later, Last Acts issued a report, *Transforming Death in America: A State of the Nation Report*, which outlined the current reality of dying in this country, the challenges, and the needed changes.10 Last Acts’ most recent study rated each of the 50 states and the District of Columbia on eight evaluative criteria on end-of-life care and was the first comprehensive measurement “report card”—a catalyst for dialogue and action.11 Education of policy makers and regulators by individuals and communities is crucial to lay out a roadmap for improvement and action in various areas, including the enactment of needed legislation10,12 (Table 58–3).

**Legislation**

Legislative initiatives have significantly influenced end-of-life care. From an historical perspective, one of the most significant pieces of legislation is the Patient Self-Determination Act (PSDA), which provides protection for the decisional authority of individuals.13 The PSDA was the first federal act to require that all Medicare and Medicaid provider organizations recognize the legal rights of the recipients of care to make decisions about their health care. This monumental legislation provided the impetus for legislative activity at the state level and the widespread acceptance of advance directives.

Simultaneous with legislative proposals related to protecting decision-making authority has been the initiation of legislation regarding DNR orders, financing mechanisms, pain management, surrogate decision-making, and PAS. These are explored further in later sections.

**Regulation**

Once the legislative process is completed with the passage of a law, there is still the need to provide specificity through regulations and rules. Federal and state administrative agencies (e.g., Health and Human Services, Justice) assume responsibility for adding the needed details of the law so that it can be understood and implemented.14 Public policy advocacy needs to include knowledge of relevant governmental agencies and access to them.

Generally, agencies release proposed regulations for public comment before the issuance of the final rule. The rule-making process is a critical point of influence in the entire legislative process. Ensuring that regulations include relevant definitions, authority, eligibility, benefits, standards, and quality measures is essential to the delivery and financing of sustainable, efficient, and improved end-of-life care.15,16 The significance of regulatory bodies and regulations should not be overlooked.

Regulatory influence extends beyond codified regulations and rules to other guidance. The Drug Enforcement Agency (DEA) joined with 21 health care organizations to endorse a statement supporting the medical use of opioids.17 Although

**Building Systems and Mechanisms of Support**

Palliative care . . .

• Requires an environment that supports innovation, research, education, and dissemination of best practices and models of care.
• Needs an infrastructure that promotes the philosophy and practice of palliative care.
• Relies on the formulation of responsible policies and regulations by institutions and by state and federal governments.
• Promotes equitable and timely access to the full array of interdisciplinary services necessary to meet the multidimensional needs of patients and caregivers.
• Demands ongoing evaluation, including the development of research-based standards, guidelines, and outcome measures.
• Ensures that mechanisms are in place at all levels (e.g., systems, direct care services) to guarantee accountability in provision of care.
• Requires appropriate financing, including the development of new methods of reimbursement within the context of a changing health care financing system.

it represented no change in DEA policy, it was an example of a partnership (between regulators and providers) that was aimed at improving end-of-life care by removing barriers to pain management. The Centers for Medicare and Medicaid Services (CMS) released a program memorandum entitled "Hospice Care Enhances Dignity and Peace as Life Nears Its End" to educate providers about the importance of hospice care and CMS' coverage of hospice care for patients at the end of life. The guidance was intended to increase awareness of hospice care, to clarify the benefit, and to encourage providers to recommend hospice to those they believe would benefit, without concern about CMS penalties. The Health Resources and Services Administration (HRSA) released *A Clinical Guide to Supportive and Palliative Care for HIV/AIDS* to improve the overall quality of care and life for those living with HIV/AIDS. Each of these documents provided further clarification and guidance for various constituencies.

### Framework for the Development of Public Policy

An initial step in the process of developing relevant public policy proposals is to determine and clarify the particular issue or problem that needs to be addressed and to ascertain the perspectives of various stakeholders on the issue. Patients, providers, payers, and governmental entities may have very different goals and ends that they are seeking. The agendas and concerns of the multiple interested parties need to be considered, negotiated, and balanced. Ultimately, a priority issue focus needs to be crafted, messaged, and delivered to any and all audiences with the ability to advance the desired agenda.

#### Spectrum of Issues Addressed in Palliative Care

#### Public Policy Proposals at the State Level

In almost every state, public interest in improving end-of-life care and the momentum for legislative initiatives at the state level have been growing. There are town meetings, state commissions, community projects, grant allocations, seminars, active coalitions, and proposed legislation. Over recent years, statewide coalitions have had a significant role in end-of-life care policy reforms. State governors, attorneys general, and the medical community have all begun to initiate activities related to end-of-life care. Recently, the National Association of Attorneys General (NAAG) released a report on the role of attorneys general in improving end-of-life care. The report identified specific areas on which attorneys general can focus, including pain management, advance care planning, education, and leading practices across the country. Although all of these interested parties may share a common goal, the focus can significantly vary from research, public dialogue, and grant projects to legislation.

Some of the impetus for public and professional interest in state policy initiatives may be the presence of controversial issues such as PAS or just a growing awareness of the present deficiencies in end-of-life care. Many, if not most, Americans have directly experienced or heard of the plight of someone facing death.

The overwhelming majority of states have some legislative initiatives proposed within the domain of palliative care. The following are examples of issues that are being addressed at the state level with specific public policy initiatives.

#### Advance Care Planning

Although all states have some type of advance directive legislation (e.g., living will, durable power of attorney for health care), there continues to be ongoing attention to the area of individual and surrogate decision-making through proposed acts or amendments to existing legislation. Legislative proposals include simplification of form and process, combining approaches into one document, removing preconditions, alternative means of availability (e.g., motor vehicle departments), and creating new approaches such as open-ended, situation-specific response forms. In addition, separate advance directives have been developed for mental health treatment and for long-term care.
A growing trend within the states has been the establishment of some form of surrogate consent provision in legislative codes. Thirty-seven states and the District of Columbia have included some type of surrogate provision in their statutes. Given the paucity of individuals who complete advance directives, this protection of appropriate decisional authority of others becomes increasingly important. Although families have historically been considered the most natural decision makers and their involvement in clinical decisions is generally normative in practice, in many states it is not always legally sanctioned. States have begun to rectify the problems created by this reality with specific legislation.

**Pain and Symptom Management**

Statutory approaches are another avenue to address concerns about appropriate pain management, and the last decade has seen many positive developments in state pain policies. A state statute can affirm justifiable and legitimate pain management practices, address appropriate disciplinary or prosecutorial actions, and provide guidance to professionals and to the courts. Several states have proposed intractable pain statutes or amendments to deal with the issue of pain management. The general goal of these state statutes and regulations is to mitigate barriers and improve pain and symptom management by creating a legal affirmation of the physician’s appropriate role in prescribing controlled substances to relieve pain without the threat of legal liability. Although the specific details of these statutes vary from state to state, they typically provide some level of protection for clinicians from disciplinary action for prescribing controlled substances for intractable pain. These statutes clearly have benefits in recognizing the legitimacy of appropriate pain management with opioids, yet there are some risks related to interpretation and application in varied situations.

States are also addressing legal, regulatory, and other policy barriers that may interfere with the effective management of pain, such as restrictive prescription monitoring laws (e.g., the requirement to use triplicate forms), dosage limitations, and patient reporting. In addition, state proposals have offered resolutions dealing with medical school education, the use of palliative care experts, and medical marijuana referendums.

If state pain policies are to continue to improve pain management, they will need to remove legislative and regulatory barriers (often focused on controlling substance abuse) that interfere with appropriate clinical care and medical decision-making.

**Do-Not-Resuscitate (DNR) Orders**

Periodically there are initiatives to expand and/or strengthen standard DNR laws (e.g., the definition of a terminal condition) that are used within inpatient settings, but the more significant activity concerns DNR orders in other settings, such as the home. Since the early 1990s, states have begun to address the needs of the seriously ill and dying in the community. An area of particular attention has been the appropriateness of resuscitative interventions by emergency medical service (EMS) teams in the home. Usually, EMS personnel are required to automatically institute cardiopulmonary resuscitation and other advanced lifesaving techniques in a crisis situation for the homebound. Many states have instituted nonhospital DNR orders to protect the wishes of individuals at home and to avoid interventions that are unwanted.

**Reimbursement**

Financing and reimbursement options are also included in state legislative initiatives. These include expansion of hospice and home health benefits, changes in eligibility requirements, reimbursement rates, medication coverage, Medicaid waivers, long-term care and nursing home reform, and attention to the care of seriously ill children. The different types of payment sources for palliative care services can include Medicare, Medicaid, private insurance, out-of-pocket, and charity care and can vary according to setting and geographic area, making it difficult to understand the actual financing realities.

**Physician-Assisted Suicide**

There has been increasing attention to legislation on PAS. State legislative initiatives started with initial proposals in California and Washington, and those initiatives paved the way for an extensive “right-to-die” campaign. The Oregon “Death with Dignity” bill, the first state legislative initiative to legalize PAS, passed in 1994 and was reaffirmed by public vote again in 1997. Since the emergence of this issue at the state level, a wide spectrum of proposals and perspectives has been offered.

States have proposals to criminalize or to legalize PAS, and some have both pending simultaneously. The criminal laws of several states have been expanded to include harsher penalties, including civil actions and the revocation of medical licenses. Although dialogue and legislative action within the states is present, Oregon remains the only state legally allowing PAS, despite ongoing challenges from the U.S. Justice Department. It may be that state legislators and the populace at large want to continue to evaluate the experience of Oregon before following suit. Oregon’s most recent report shows there has been an increase in the number of patients taking lethal medication, but that it is a relatively small number compared to total deaths in the state. There is indication that the existence of legally permissible PAS has led to efforts to improve end-of-life care generally through other options.

**Federal Legislative Proposals**

As is occurring at the state level, the federal government has been directing attention to issues of end-of-life care. Often, the attention occurs through the budgeting process when funds...
are allocated for Medicare and Medicaid services (e.g., hospice benefit) and through appropriations for health agencies (e.g., National Institutes of Health). Additionally, governmental entities have begun to address concerns about pain control, advance care planning, and PAS. Through the 1990s and into the early 2000s, many federal legislative proposals were introduced; some had success in one or both congressional bodies (U.S. Senate and House of Representatives), but all ultimately failed to become law. Examples of current federal legislative proposals follow.

Conquering Pain Act of 2003

This legislation was reintroduced with modifications in the House and Senate after receiving very little attention as the Conquering Pain Act of 1999 and 2001. The current bill is intended to establish Family Networks for Pain Management to improve access to and quality of end-of-life care and serve as national models for replication.38

National Pain Care Policy Act of 2003

This legislation amends the Public Health Services Act to establish a National Center for Pain and Palliative Care Research within the National Institutes of Health.39 It is intended to increase awareness, improve, and advance the quality, appropriateness, and effectiveness of pain management and palliative care through research, grants, public campaigns, and education. In addition, the bill includes provisions to improve access to care in federally financed institutions and health plans.

Children’s Compassionate Care Act of 2003—Pediatric Palliative Care Act of 2003

This legislation to improve palliative care for children was introduced in both the House of Representatives and the Senate. The content of the two bills is virtually the same, and the aim is to create pediatric palliative care demonstration projects and provide grants to expand services, training, and research.40,41

Living Well with Fatal Chronic Illness Act of 2003

This legislation addresses the issues surrounding fatal chronic illnesses by requiring federal agencies to expand and improve research, demonstration projects, education, clinical treatment, and care services.42 Further, the bill relates to respite services for caregivers, long-term care financing, and home health care.

Life Span Respite Care Act of 2003

This Senate-passed legislation authorizes millions of dollars in competitive grants to states and other qualifying entities to make respite care available to family caregivers.43 Although the House of Representatives has a companion bill, most efforts are focused on having the Senate bill considered and passed in the House, which could expedite enactment.

Medicare Prescription Drug Improvement and Modernization Act of 2003

After many years of consideration, the "Medicare Prescription Drug Improvement and Modernization Act of 2003" (the "Act") was signed into law (P.L. 108–173) on December 8, 2003.44 The legislation has drawn attention primarily because of the new Medicare drug benefit, but there are many other significant provisions contained in the Act, including those that benefit the chronically ill and dying. Although many of the accompanying regulations to the legislation have yet to be developed and disseminated, such improvements are lauded among end-of-life advocates. There are several provisions to improve access to hospice care and to make services more available to patients and families earlier in their illnesses. The Act addresses hospice payments for beneficiaries and consultative education, expanded contracting opportunities, and rural hospice care.

The Act also recognizes nurse practitioners in the role of attending physicians to care for hospice patients. Under existing law, only an attending physician, medical director, or other physician at the hospice can certify a patient as terminally ill and determine the medical care to be delivered. The Act now expands the definition of attending physician in hospice to include nurse practitioners, although they are still not permitted to certify a patient as terminally ill for the purposes of receiving the hospice benefit.

Public Policy and Physician-Assisted Suicide

At both the federal and state level, attention to the legalization of PAS has escalated throughout the last decade. Since the early 1990s, the majority of states in this country have grappled with this issue. The highest court, the Supreme Court of the United States, addressed the issue of an individual’s right to PAS. The fact that this issue found its way to the nation’s highest court is symbolic of the growing acceptability of PAS as a tenable choice.

The Supreme Court reversed the holdings of two lower courts45,46 and found that there is no constitutionally protected right to PAS on behalf of terminally ill patients.47 The ruling of the Supreme Court does not prohibit individual states from legalizing such practices in the future. Probably one of the most significant aspects of the Court’s decision was the attention directed at the urgent need to improve the quality of end-of-life care.47 The Court demonstrated enormous sensitivity to the plight of the dying in the present health care system and emphasized the importance of effective pain relief for the dying.47

The nursing community became actively engaged in the debate and activities surrounding the PAS issue. Major professional and specialty nursing organizations struggled with the associated complex moral and professional issues. Nurses have invaluable experience and insight into care at the end of life, which informs the assisted suicide debate and guides the profession’s response. The development of position statements48 (Table 58–4) and educational resources, involvement in professional...

collaborations and end-of-life coalitions, provision of testimony to congressional leadership, and submission of an amicus curiae brief with other health-professional organizations to the Supreme Court of the United States were some of the important activities supported by and engaged in by the nursing profession.49,50 For more information on PAS, the reader is referred to Chapter 59.

The Role of Nurses in Palliative Care Public Policy

Advocacy is generally considered a prominent component of professional nursing practice. Advocacy is most frequently understood by nurses in their clinical, patient-centered experiences; however, a broader perspective of advocacy is called for. Professional commitment must also express concern for the wider community, for society, and particularly for those who are most vulnerable. The skills that nurses use in their clinical, research, educational, and administrative roles can be extremely valuable and transferable into legislative and political arenas.31

Undoubtedly, public policy initiatives will continue to emerge at the state and federal levels, and nurses can assume an important role. Nurses need to remain in the forefront as advocates for improved end-of-life care, and they need to see public policy advocacy as yet another growing opportunity to demonstrate this commitment.

Nurses have most frequently been the professionals who have attempted to provide appropriate, competent, and compassionate care to individuals and families who confront the brevity of life. As the largest group of health professionals and those most connected to the comprehensive needs of the terminally ill and their families, nurses are obligated to provide leadership that advances improvements in end-of-life care.

Nurses, individually and collectively, must be interested in and become involved in the assessment of proposed end-of-life legislation and regulation. A proactive, responsible stance on the part of nurses can influence the creation and evaluation of needed end-of-life initiatives. Nurses bring an understanding of the present state of end-of-life care that helps in the analysis of appropriate public policy options and can craft future initiatives.

The Code for Nurses with Interpretive Statements (Code for Nurses), the profession’s code of ethics, directs nurses “to engage in political action to bring about social change.”92 The Code for Nurses affirms the role of professional associations in acting on behalf of nurses to shape health care policy. Ethical values that undergird professional responsibilities, such as respect for autonomy, justice, professional integrity, beneficence, and advocacy, interface with the goals of improving end-of-life care and provide a context for assessment of policy proposals.

Although nurses may individually engage in public policy initiatives, it is most often through their involvement in entities such as professional associations or coalitions that advocacy efforts are effectively advanced. These entities can catalyze and promote concerted action on priority issues.31 For example, the Hospice and Palliative Nurses Association formed a partnership with other organizations (American Academy of Hospice and Palliative Medicine and National Hospice and Palliative Care Organization) to form the Hospice and Palliative Care Coalition (HPCC) to advocate for improved end-of-life care in this country34,55 (Table 58–5). Unifying the voices of interested and invested constituencies can have a powerful impact on legislators and regulators. Depending on the importance of a particular issue, the nursing community may assume different roles and levels of activism. At times, the nursing community may act as the leader, advancing a particular public policy concern; at other times, it may choose to provide endorsement or support of an issue.

Nurses can and should become actively involved in the legislative and regulatory processes by gathering necessary information, providing the perspectives of not only professionals but also the recipients of care, evaluating policy proposals, communicating with policy leaders, and lobbying on specific bills.36–38 The more knowledgeable individuals are about the legislative process, the more effectively they can participate and influence outcomes. Health care policy that is developed without the input of nurses lacks an important influence because of the unique and essential role that nurses have in the care of patients, families, and communities.39 Involvement by nurses in public policy and political advocacy through various activities is yet another way to demonstrate professionalism and promote improvements in end-of-life care40 (Table 58–6). Nurses

can provide a critical and valuable voice in professional, public, and governmental discourse about end-of-life care.

**Conclusions**

Public policy initiatives at state and federal levels of government can provide another avenue to advance improvements in end-of-life care. Nurses can inform and influence the process of developing, evaluating, and enacting palliative care public policy that benefits individual, family, and community end-of-life care. Involvement in public policy advocacy provides nurses an opportunity to assume their professional citizenship responsibilities and to positively affect the quality of end-of-life care provided throughout the United States.

**REFERENCES**

Key Points

Palliative care nurses do encounter patient and family questions, concerns, and requests for assisted dying. Withholding and withdrawing life-sustaining measures and provision of pain relief are not acts of assisted dying. Individuals with life-limiting disease who may consider assisted dying include those experiencing unrelieved pain, depression, hopelessness, psychological distress, spiritual distress, poor social support, poor quality of life, or a perception of being a burden on others. Nurses should respond to requests for assisted dying in a manner that reflects professional guidelines and a sense of advocacy for patient rights for quality end-of-life care.

The concept of palliative care, as described by the World Health Organization, is in direct conflict with the idea of deliberately hastening a person’s death via the practice of assisted dying (AD). Indeed, palliative care “intends neither to hasten nor postpone death.” Yet patients may be fearful of the extreme discomfort they anticipate, or they may simply want some certainty as to the timing or circumstances of death. Nurses who care for patients with life-limiting disease encounter patient and family questions, concerns, and requests for AD. Receiving such a request can represent a morally troubling dilemma in which there is uncertainty about how best to respond. The purpose of this chapter is to review the ethical and legal status of AD, summarize empirical findings regarding both professional and lay opinions and experiences with AD, and offer guidelines for responding to requests for AD.

What Is Assisted Dying?

The term “assisted dying” is typically used to describe an action in which an individual’s death is intentionally hastened by the administration of a drug or other lethal substance. This may take the form of either assisted suicide or active euthanasia. Assisted suicide is defined as “making a means of suicide available to a patient (e.g., providing pills, weapon) with knowledge of the patient’s intention. The patient who is physically capable of suicide subsequently acts to end his or her own life.” Active euthanasia occurs when “someone other than the patient commits an action with the intent to end the patient’s life.” Such an action can be voluntary (e.g., requested by a competent individual) or involuntary (administered without the individual’s knowledge or consent).

It is important to distinguish between the concept of AD and other actions designed to allow patients to die as comfortably as possible. Withholding and withdrawing life-sustaining measures are actions designed to not interfere with the natural
trajectory of an illness. That is, life-sustaining measures such as artificial ventilation, renal dialysis, cardiopulmonary resuscitation, or artificial nutrition and hydration are withheld or stopped; the patient subsequently dies due to the effects of disease. In this instance, the intent of the action is to allow a natural death, and the cause of death is the underlying illness. In AD, the intent of the action is to hasten death, and the cause of death is the lethal drug or other means administered to end life. Intent and causation are the key concepts that differentiate the two actions. Some practitioners worry that administration of sufficient doses of pain medication and other drugs designed to relieve suffering may hasten death and therefore may constitute AD. However, this is not an action of AD. It does not qualify as AD because the intent is to relieve suffering, even though there may be a foreseen possibility that the medications could result in a hastened death. This is an example of the ethical principle of double effect, in which a good effect (relief of pain or other symptoms) is the goal despite the possibility of an unintended, harmful effect (a hastened death). The reader is referred to Chapters 6 and 57 for more information on the principles and ethics of proper pain management.

What Are the Ethical and Legal Issues?

The ethical issues associated with AD have been extensively described.4–6 In essence, those who support the practice cite the patient’s right to determine his or her own fate (autonomy), relieve untenable suffering, and maintain control over the end of life. Also relevant is the issue of equity, in that patients who are not dependent on life support do not have the same access to ending life as patients who can deliberately end life by discontinuing a ventilator, for example. Those who believe AD is unethical worry that the practice will erode trust in health care professionals, deny the sanctity of human life, discourage efforts to make palliative care available to all, and initiate a “slippery slope” in which vulnerable, underserved, or disenfranchised patients will feel pressured to take a quick way out with death. The health care professions’ ethical codes and position statements uniformly oppose the practice of AD. Table 59–1 summarizes nursing organizations’ relevant codes and statements.

Active euthanasia is illegal throughout the United States, whereas the Netherlands and Belgium have legalized both assisted suicide and active euthanasia under certain circumstances.7 Australia briefly enacted a law that legalized both active euthanasia and assisted suicide; the statute was passed in 1996 and repealed a year later.

Worldwide, the Netherlands has had more experience with the practice of active euthanasia than any other country. Euthanasia was legally sanctioned via a series of court decisions in the Netherlands beginning in the 1970s; euthanasia and physician-assisted suicide were legalized in 2000 by the Dutch parliament.8 Controversy exists as to whether increasing tolerance of these practices by physicians and the public has led to an increase in their use and a lesser emphasis on palliative and hospice care. Onwuteaka-Philipsen and colleagues9 studied end-of-life decision-making practices by physicians in the Netherlands in 1990, 1995, and 2001. They concluded that the incidence of physician-assisted death had not risen since 1995. However, they did not evaluate quality of end-of-life care, nor did they obtain views of patients or family members.

In an overview of the Dutch experience with euthanasia, Hendin8 asserted that regulations limiting euthanasia to a voluntary practice are frequently violated and that patients are put to death without their consent. Indeed, he claimed that “euthanasia intended originally for the exceptional case has become an accepted way of dealing with the physical and mental distress of serious or terminal illness” (p. 223). Ongoing study of AD in the Netherlands is anticipated.

Assisted suicide was legalized in Oregon in 1997 with the passage of the Death with Dignity Act via two citizen referenda separated by 3 years. This Act allows a terminally ill person to obtain a prescription for a lethal dose of medication with the prescribing physician’s understanding that the intent of the medication is to end life. Eligible patients must meet several criteria, including being at least 18 years of age, an Oregon resident, capable of making health care decisions, and diagnosed with a terminal illness that will cause death within 6 months.10 The patient who requests a prescription must make two oral requests (separated by at least 15 days) to his or her physician and provide a written request that is signed in the presence of two witnesses. The prescribing physician and a consulting physician must confirm the diagnosis and prognosis and determine whether the patient is competent to make the decision. If either physician believes the patient’s judgment is in question, the patient must be referred for a psychological examination. The prescribing physician must discuss alternatives to assisted suicide (comfort care, hospice care, and pain control) with the patient and must request (but not require) that the patient notify next-of-kin of his or her plans.10 The Act was challenged in 2001 by the U.S. Attorney General, who asserted that physicians who prescribe lethal doses of drugs are violating federal laws regarding controlled substances. To date, the State of Oregon has prevailed in court rulings.11

Who Wants Access to Assisted Dying and Why?

It is not unusual for terminally ill people to desire a hastened death. People who have life-limiting diseases such as cancer, degenerative neurological disorders, acquired immunodeficiency syndrome (AIDS), or end-stage cardiovascular or renal disease have been identified as individuals who may be interested in access to AD. A variety of studies reveal characteristics of those who have expressed a desire for hastened death. Meier and coworkers12 conducted a national survey of physicians who had received requests for assisted suicide to determine the demographic and illness characteristics of patients who had

(continued)
such requests denied or honored. Of the 1902 physicians who responded, 63% described instances of receiving requests, and 80 requests were honored. Requesting patients were seriously ill, suffered from pain and other physical discomfort, and were near death. Physicians who honored requests were more likely to do so if the patient was in severe pain or discomfort, had a life expectancy of less than 1 month, and was not considered to be depressed.

Unrelieved pain is a major risk factor for suicide among cancer patients. Numerous studies have shown that the overwhelming majority of cancer patients who have died by suicide have had poorly controlled and poorly tolerated pain. The role of depression and hopelessness in requests for a hastened death also is well known. For example, in a study of 92 terminally ill cancer patients, Breitbart and colleagues found that depression and hopelessness were the strongest predictors of a wish for a hastened death. Other factors associated with desire for hastened death include psychological distress, spiritual distress, poor social support, poor quality of life, and the perception of being a burden to others. Of note is a study of the will to live in cancer patients in palliative care, in which Chochinov and colleagues concluded that the will to live is a communication tool used by the dying to communicate their desire for death, thereby prompting caregivers to address unmet needs.

Ganzini and Block asserted that patients with amyotrophic lateral sclerosis (ALS) are more likely than other terminally ill patients to request AD. In a Washington and Oregon study of attitudes of patients with ALS (n = 100) and their family caregivers (n = 91) toward assisted suicide, these researchers found that 56% of the patients would consider assisted suicide. Compared with patients who opposed assisted suicide, those who did not were more likely to be male, better educated, and less religious and to have higher levels of hopelessness and a lesser quality of life. Notably, Ganzini and Block asserted that no relationship exists between depression and hopelessness in ALS patients’ desire for assisted suicide, and that hopelessness may be a better predictor of interest in AD. They postulated that hopelessness represents feelings about the future and can occur without depression per se. They also speculated that the invariable progression of the disease process, coupled with poor symptom management and substantial family caregiver burden, may contribute to requests for assisted suicide by people with ALS.

Experience with legal assisted suicide in Oregon reveals another picture. During the first 5 years of the Death with Dignity Act, 129 patients took lethal medications to end their lives, whereas 42,274 other Oregonians died from the same underlying illnesses. The characteristics of Oregonians who died from assisted suicide included older age (mean, 69 years), non-Hispanic White race, and college level of education. Most had a diagnosis of either cancer or ALS and were enrolled in hospice care. The most common end-of-life concerns voiced included loss of autonomy, decreased ability to participate in enjoyable activities, and loss of control over bodily functions.

Despite access to legal AD, or perhaps because of it, Oregon has become a national leader in improving planning for end-of-life care. Indeed, Oregon has the lowest rate of in-hospital deaths and high rates of written advance directives and do-not-resuscitate orders. An Oregon physician has speculated that the Death with Dignity Act may have resulted in prevention of some suicides by allowing patients to openly communicate their desire for death, thereby prompting caregivers to address unmet needs.

Recently, Coyle and Sculco conducted a phenomenological study to investigate the meaning and uses of expressed desire for hastened death in seven patients living with advanced cancer. They concluded that expression of desire for hastened death constituted a communication tool used by the patients. Analysis of patient interviews revealed that meanings and uses of expression about desire for hastened death manifested in a variety of ways. Examples included expressions as a manifestation of the will to live, that the dying process itself was so difficult that an early death was preferred, and that the immediate patient situation was unendurable and required immediate action. The investigators observed that a request for hastened death may not be a literal expression of desire.

for suicide and may take on many meanings and uses for patients. Nurses should listen carefully to patient requests and associated stories to better understand what the patient is asking for.

How Do Nurses Respond to Requests for Assisted Dying?

Given their pivotal role in providing palliative care, nurses often may encounter patient requests for AD. Survey studies have captured nurses’ experiences with receiving requests for AD. For example, Matzo and Emanuel\(^2\) surveyed 441 New England oncology nurses and discovered that 30% had received requests for assisted suicide, 1% had engaged in assisted suicide, and 4.5% had injected a drug to intentionally end a patient’s life. In a national survey of more than 2333 nurses,\(^2\) 23% had received patient requests for assistance with obtaining a lethal prescription, and 22% had patients who requested that they be injected with a lethal dose of medication.

Qualitative studies have also been conducted to capture nurses’ experiences with AD. Volker\(^2\) analyzed 48 anonymously submitted stories of oncology nurses’ experiences. Some of the nurses’ stories reflected patient’s, family’s, or health care provider’s desires for control over an uncontrollable end-of-life experience. Many stories reflected nurses’ moral conflicts over how to respond to patient or family requests for AD; covert communication among nurses, physicians, and family members regarding agreement to intentionally hasten death; and a sense that the experience of receiving such a request had an enduring influence on future practice. Schwarz\(^3\) interviewed 10 nurses from hospice, AIDS, critical care, and spinal cord injury practice settings to discern their experiences with being asked to help someone die. The nurses spoke both of unintentionally hastening death via clinically appropriate symptom management (illustrative of the principle of double effect) and, on occasion, of knowingly intending death. Many expressed feelings of conflict, guilt, and moral distress. Notably, the context of a patient’s request for AD shaped the nurses’ responses; neither codes of ethics nor professional position statements were used.

The experience of Oregon nurses with hospice patients who requested assisted suicide has also been examined. Of 82 hospice nurses who reported on 82 patients who had died by assisted suicide (in accordance with the Death with Dignity Act), Ganzini and colleagues\(^4\) ascertained that 98% had discussed the patient’s request with coworkers; 77% of the requests were discussed at an interdisciplinary patient care conference. The nurses reported that the most frequent reasons patients gave for wanting assisted suicide were the desire to control the circumstances of death, readiness for death, and the desire to die at home. The least frequent reasons were lack of social support, nausea or fear of worsening nausea, and depression or other psychiatric disorder.

How Should Nurses Respond to Requests for Assisted Dying?

Of the myriad communication skills expected of nurses, responding to requests for AD can be the most difficult.\(^5\) Regardless of his or her personal feelings about the moral acceptability of AD, the professional nurse has a responsibility to respond to a patient’s request for AD in a compassionate, sensitive way. The patient advocacy role of nursing is central to that response. Table 59–1 summarized the guidelines that professional organizations offer to assist nurses in formulating responses to requests for AD. In particular, the Oncology Nursing Society\(^6\) has emphasized that “requests for assisted suicide should prompt a frank discussion of the rationale for the request, a thorough and nonjudgmental multidisciplinary assessment of the patient’s unmet needs, and prompt and intensive intervention for previously unrecognized or unmet needs” (p. 442). Table 59–2 provides guidelines for exploring a request for assisted suicide. Additionally, Scanlon\(^7\) has identified nursing actions that include exploring the patient’s treatment goals and options; assessing the patient for depression, decisional capacity (especially regarding informed consent), cognitive function, and spiritual distress; documenting the patient’s request; and remaining present with the patient who chooses an assisted suicide. The Oregon Nurses Association\(^8\) has published detailed guidelines for nurses who choose to be involved in an assisted suicide, as well as guidelines for those who choose not to be involved (Table 59–3). In either case, nurses may not inject or administer medication intended to end life; subject the patient, family, or other health care team members to judgmental comments or actions; or refuse to provide comfort and safety measures to the patient.

Are There Alternatives to Assisted Dying?

The wish for a peaceful, comfortable death is not unreasonable. Given that AD is not a viable moral or legal option for many individuals, what are the alternatives that could fulfill a desire to control the circumstances of the dying process? The obvious answer is universal access to expert palliative care. Indeed, there is strong moral consensus among health care providers that untreated suffering must never be a justification for AD. However, there are legally and ethically sanctioned options other than AD that may be palatable for some individuals. Refusal of medical treatment is a widely respected means for allowing the dying process to unfold unimpeded by treatments that will not fulfill the patient’s personal goals for the end-of-life experience. Refusal may be in the form of withholding or withdrawing a life-sustaining treatment.

The individual who is not dependent on medical interventions to sustain life and wishes to control the timing of his or her death is faced with a more perplexing challenge.
Voluntary refusal of food and fluids has been identified as a possible option. Although such action requires no direct participation by the health care team, nurses can support patients who choose this option by ensuring optimal comfort measures and family support. Depending on the patient’s underlying condition, death usually occurs within 1 to 3 weeks. Concern has been voiced regarding discomforts that could accompany this action. To evaluate this possibility, Ganzini and associates surveyed hospice nurses who had cared for terminally ill patients who deliberately hastened death by cessation of eating and drinking. Thirty-three percent of their 307 respondents reported that they had cared for such patients. The most common reasons given by patients for this choice were readiness for death, poor quality of life or fear of poor quality of life, view that continued existence was pointless, and desire to die at home. Most

of the patients had either cancer or a neurological disease; 85% of the patients died within 15 days after ceasing intake of food and fluids. The nurses were asked to rate the quality of these patients' deaths on a scale from 0 (a very bad death) to 9 (a very good death); the median score for this sample was 8. The authors concluded that, from the perspective of the nurse participants, most of the patients died a good or peaceful death. Of note, no family or patient perspectives were obtained in this study. Future research should focus on evaluating these perspectives.

The practice of palliative sedation represents another alternative to AD. Palliative sedation refers to the use of medications to relieve refractory symptoms in the dying patient by causing unconsciousness, but not death. The goal is to relieve suffering, not to cause death. A detailed discussion of this practice is provided in Chapter 24. Palliative sedation may be ethically troubling for both family and professional caregivers, because some do not differentiate between this practice and active euthanasia. Palliative care experts can provide guidance to assist patients, families, and professionals with appropriate use of sedation and to distinguish palliative sedation from hastened death. In addition, some patients may not find this choice acceptable because they view induction of unconsciousness until the time of death as undignified and as prohibiting communication with loved ones in those final days or hours.

CASE STUDY

A Request for Assisted Dying

In the following scenario, a home hospice nurse described an experience of receiving a request for a hastened death from a 25-year-old man with end-stage AIDS.

“I was asked by this patient, ‘Can’t you do something to end this pain and suffering now? Something that will end my life?’ This patient had lived with pneumonia, Kaposi tumors, constant lung infections, skin eruptions, and joint and limb pain. He had spent all his savings, sold most of his furniture, and mortgaged his house to pay for medical expenses. He had not worked for 3 months, and his partner had left him. My response was straightforward and reassuring: ‘Pain control starts today, and before I leave you, you will feel less pain.’ I could not give him something to end his life. My presence and work is to eliminate as much pain as possible and to keep him comfortable at home. Quick phone calls to the physician for pain relief medication and quick delivery helped. We discussed at length what was causing him to want to die at that moment. Pain was his biggest reason. He was depressed with his circumstances—no money, more than 25 pills a day (when he had never taken an aspirin when he was healthy), no visits from his friends (even to help him get to the doctor’s office), and no way to continue his job. Also, loss of sleep and poor vision were contributors. Once his pain relief was achieved, he was able to sleep. With the hospice team, a social worker, and volunteers to help with his daily needs, my weekly visits were a mixture of comforting and counseling. He asked three times over a month’s time to help him end his life. My inner feelings were conflicted. He was going to die; why not let him die by his choosing? My oath to administer to the sick and do no harm must be upheld. How else do we keep a measure of control on end-of-life issues? I feel I did my job correctly, but did I serve this man’s needs? I do not know.”

Conclusion

Although many requests for AD can be resolved by the application of expert palliative care, a small subset of individuals may seek AD despite such care. Nurses are responsible for responding to patient requests in a manner that reflects professional guidelines and a sense of advocacy for patient rights for quality end-of-life care. Regardless of personal values or discomfort with a request for AD, nurses must apply open communication techniques that allow exploration of patients’ needs and fears about the final phase of life.

Nursing Education

It is imperative to integrate current clinical practice expertise into education to keep pace with the progression of medical treatments and patient care.—Carol R. Matthews, MSN, CNS, BC-PCM, 1999 graduate of The Breen School of Nursing Palliative Care Masters Program

Key Points
- There is a need for palliative care nursing education.
- Knowledge deficits exist among nurses regarding palliative care.
- Model academic programs are available for education in palliative care nursing.

One of the earliest responsibilities of the professional nurse was care of the dying. Florence Nightingale and other nurses provided care to soldiers dying on battlefields as well as to civilians dying as a result of epidemics. A major shift in patterns of disease and treatment began in the 20th century as more effective treatment modalities became available. Today, student nurses are exposed primarily to curative-oriented care and are less likely to encounter comfort-oriented care. Although many health care providers work with people at the end of their lives, nurses spend the most time with the dying and their families. Most nurses will provide palliative care to patients and their families no matter where they practice. Therefore, education in palliative care should begin in the nursing schools and extend through clinical inservices, continuing education courses, and professional conferences.

The Need for Improved Palliative Care Nursing Education

It is imperative that nurses learn through both didactic and clinical experiences. Working with a palliative care or hospice team provides the best experience for learning about the interdisciplinary approach to patient care as the team members model excellence in care for the student. Many studies of end-of-life knowledge, attitudes, and skills of nurses provide evidence of the need to improve the education of nursing students, practicing nurses, and nursing faculty. This chapter focuses on the role of nursing education in palliative care. An overview of the need to improve palliative care nursing education includes a brief history of nursing care of the dying, knowledge deficits, and the current focus on these deficits. Issues and challenges in palliative care education are discussed. Several models of nursing education programs are presented.
Many people, especially nurses and physicians, have been instrumental in developing a framework for care of the dying and their families. Dame Cicely Saunders is credited as the founder of the modern hospice movement. She was educated first as a nurse and later as a physician in London. Her interest in pain management led her to care of the dying. With support from the community and the national government, she founded St. Christopher’s Hospice in Sydenham on the outskirts of London in 1967. At about the same time, Dr. Elizabeth Kubler-Ross, a psychiatrist, began interviewing dying patients in hospitals. She found it difficult to find these patients because doctors and nurses repeatedly told her that there were no dying patients in their hospitals. She later proposed a model that described the five stages of dying.

Jeanne Quint’s landmark study in 1967 revealed little emphasis throughout the nursing curriculum on teaching nursing students to care for dying patients. Teaching and support were particularly lacking in the clinical setting. Nursing instructors were inadequately prepared to teach or support the students in care of the dying and were not comfortable with nursing problems associated with dying patients. She recommended that faculty standardize death education curricula so that they could be offered consistently throughout schools of nursing and continuing education.

Recognizing Deficits in Pain Education in the 1980s and 1990s

Many research studies have documented the lack of knowledge about pain management among student nurses, practicing nurses, and nursing faculty. Studies have documented serious misconceptions in the assessment and treatment of pain and knowledge deficits in basic areas such as opioid pharmacology, use of adjuvant medications, and treatment of side effects. A recent national report documented poor pain management among nursing home residents and deficits in state pain policies. These studies have been instrumental in encouraging greater emphasis on pain management in nursing education programs and the significant need to provide pain education to practicing nurses.

The awareness of educational deficits in the specific area of pain education extended in the late 1990s to the broader area of end-of-life content in nursing education. Many studies have documented the inadequate preparation of nurses to care for patients and their families at the end of life. Several research studies have described important nursing behaviors in the care of the dying. Inadequate professional education is often cited as a major barrier to appropriate end-of-life care. In Webster’s 1981 study, more than 30% of the student nurses reported that they were not always told which of their patients were expected to die. Additionally, 60% were not told whether the patients knew they were dying. Care of the dying patient was not routinely incorporated into their curriculum. The type and amount of knowledge and support were dependent on the instructor. Although the students may have learned these skills by working with more experienced nurses, observations revealed that 25% of the students worked alone with the dying, and the remaining 75% had only intermittent supervision.

Rittman and colleagues identified five themes that were common among expert oncology staff nurses. They included knowing the patient and the stage of the disease, preserving hope, easing the struggle, providing for privacy, and responding to the spiritual aspects of living and dying. The nurses were able to maintain a high standard of practice by incorporating these themes into their clinical practice to provide for a peaceful death for their patients. They found that nurses who were able to deal with their own mortality became more comfortable with death.

Several studies have analyzed end-of-life content in nursing textbooks. Kirchhoff and colleagues analyzed 14 critical care nursing textbooks using the American Association of Colleges of Nursing (AACN) end-of-life competencies for undergraduate nursing education as their framework. Four additional end-of-life content areas were identified during the analysis. None of the textbooks contained all of the content areas. Although there was extensive information on ethical and legal issues, organ donation, and brain death in six or seven of the textbooks, the remaining textbooks contained no information on these topics. Pharmacological information was either mentioned briefly or absent. Approximately half of the textbooks had some information on patient/family communication.

Ferrell and colleagues completed an analysis of nine areas of end-of-life content in nursing textbooks. Their review of 50 nursing textbooks revealed that only 2% of overall content was related to end-of-life care, and much of the information was inaccurate (Table 50–1). Deficiencies were found in all areas. Palliative care was usually discussed in terms of the hospice model of care rather than the broader concept of palliative care. There was little information on quality of life, which was surprising in view of the recent explosion of research in this area. Pain was often included in the textbooks, but usually in the context of acute rather than chronic pain. Pain management during the end of life was virtually absent. Major gaps were found in symptom assessment and management. Information about communicating with patients and families at the end of life was also lacking. There was little information about the roles and needs of family caregivers or about issues of policy, ethics, and law. A paucity of information was found about death awareness, anxiety, imminent death, and preparing families for the death. The stages and process of grief were described, but there was little information about nursing interventions or the nurse’s personal grief.

Another component of this project was the collaboration with the National Council of State Boards of Nursing, Inc. (NCSBN). The goal of this project was to improve end-of-life content in the national nursing licensure examination for registered nurses (NCLEX-RN). End-of-life content was increased in the NCLEX beginning with the April 2001 examination by incorporating the 15 competencies set forth by the AACN in the Peaceful Death document. This was a significant force in increasing end-of-life content in the nursing curriculum.
Each of these studies has consistently echoed the strong message that improved patient care is contingent on adequate preparation of nurses. The deficits cited in these studies provide direction for needed areas of education.

The Issues and Challenges in Palliative Care Education

The World Health Organization (WHO) has recognized the need for the development of national policies and programs for palliative care and has issued several recommendations regarding the education and training of health care professionals. In addition, WHO has suggested that palliative care programs be incorporated into the existing health care system.

Another key document, the Institute of Medicine’s 1997 report on improving end-of-life care, made several recommendations specific to improving professional knowledge. Three of these related specifically to education:

Recommendation 2: Physicians, nurses, social workers, and other health care professionals must commit themselves to improving care for dying patients and to using existing knowledge effectively to prevent and relieve pain and other symptoms.

Recommendation 4: Educators and other health professionals should initiate changes in undergraduate, graduate, and continuing education to ensure that practitioners have relevant attitudes, knowledge, and skills to care well for dying patients.

Recommendation 5: Palliative care should become, if not a medical specialty, at least a defined area of expertise, education, and research. Palliative care experts should provide expert consultation; serve as role models for colleagues and students; supply leadership for undergraduate, graduate, and continuing education; and organize and conduct research.

The Institute of Medicine report cited major deficiencies in professional education for end-of-life care. These included the relative absence of death in the curriculum, a lack of educational materials pertaining to the end stages of most diseases and neglect of palliative strategies, and the lack of clinical experiences with dying patients and those close to them. The report suggested that educators could improve care by doing the following:

1. Conferring a basic level of competence in care of the dying patient for all practitioners
2. Developing an expected level of palliative and humanistic skills considerably beyond this basic level
3. Establishing a cadre of superlative professionals to develop and provide exemplary care for those approaching death, to guide others in the delivery of such care, and to generate new knowledge to improve care of the dying.\(^1\)

A recent national report card on dying in America encouraged the development of hospice or palliative care service rotations in nursing education and requirements for continuing nursing education in end-of-life care.\(^3\) Educational programs for nurses in palliative care vary widely throughout the world. There are established courses and programs in palliative care at universities as well as seminars, workshops, and conferences in the Americas, Australia, the United Kingdom, and elsewhere in northern Europe. In other parts of the world, education in palliative care is woven into other courses. Palliative care concepts are taught within oncology courses in Japan and Thailand. Since 1990, the Nairobi Hospice in Kenya has provided palliative care courses for health care professionals and has extended this program to nursing schools throughout Kenya. They are working to incorporate palliative care into the nursing curriculum. An increase in the availability of charitable sources has resulted in support for the development of palliative care in Russia and the Czech Republic.\(^29\)

There are many challenges in improving palliative care education. All educators struggle with how best to integrate more content into an already packed curriculum. Nurse educators have described undergraduate programs designed to incorporate end-of-life content into the curriculum through didactic and practicum courses.\(^30\)\(^,\)\(^31\) Other academicians have described the process of developing interdisciplinary courses at the graduate level.\(^32\) There also is tremendous need to increase the knowledge of faculty in palliative care so that they can lead the change in curriculum. Faculty also require current teaching guides such as audiovisual materials, case studies, and other resources to present this challenging content.

Teaching palliative care is not only a matter of didactic content. Preparing nurses to care for the terminally ill necessitates attention to the student’s values, beliefs, personal experiences, and culture. It is essential that palliative care education not only incorporate knowledge and skills but also strive to identify methods to best enhance compassion, empathy, and the existential aspect or “art” of palliative nursing.\(^33\)\(^-\)\(^37\)

The Nursing Profession’s Response to the Need for Change

In recent years, major professional nursing organizations have recognized the importance of nursing response to the mandate for improved end-of-life care. In 1997, the International Council of Nurses mandated that nurses have a unique and primary responsibility for ensuring that individuals at the end of life experience a peaceful death.\(^38\) In the same year, the AACN convened a roundtable of expert nurses and other health care professionals to address this topic. The report from that meeting was titled \textit{Peaceful Death}.\(^27\) This document outlined 15 competencies necessary for nurses to provide high-quality care to patients and families during the transition at the end of life. These competencies should be attained before graduation from undergraduate programs of nursing. The group also made recommendations concerning the curriculum content areas in which these competencies could be addressed (Table 60–2).

At about the same time, the Nurses Section of the National Hospice Organization, under the direction of Cindy Yocum Scott and Nancy English, developed the \textit{Guidelines for Curriculum Development on End of Life and Palliative Care in Nursing Education}.\(^39\) Separate guidelines were prepared for undergraduate and graduate nursing programs. They included the biological, psychosocial, and spiritual responses to dying. Theory, assessment, interventions, and clinical placement were addressed within this conceptual framework (Table 60–3).

Dr. Cynda Hylton Rushton, faculty of the School of Nursing of Johns Hopkins University, and colleagues at the Institute for Johns Hopkins Nursing convened a meeting of 23 nursing specialty groups in 1999 to design an agenda for the nursing profession on palliative and end-of-life care.\(^40\) The group, the Nursing Leadership Consortium on End-of-Life Care, consisted of nursing organizations with administration, research, practice, and policy responsibilities and created a priority map for the nursing profession. The Nursing Leadership Academy for Palliative and End-of-Life Care continued the work of the Consortium.\(^41\)\(^,\)\(^42\) In 2000, leaders from 22 nursing organizations met for 5 days to develop action plans to address key issues in end-of-life care in their organizations. This effort was repeated with another cohort in 2002, raising the number of participating organizations to 44. The project was funded by Project on Death in America.

In 2001, Dr. Ira Byock convened a group of palliative care advanced practice nurses (APNs) with expertise in clinical practice, education, and research to discuss the state of advanced practice nursing in palliative care in the United States and to make recommendations for the future development of this emerging nursing specialty. They recommended that nurse educators become more familiar with palliative care, develop continuing education to prepare current APNs in palliative care competencies, integrate the competencies into the education of all APNs, and develop clinical tracks for APN students who intend to specialize in palliative care. The Robert Wood Johnson Foundation funded this project through the Promoting Excellence in End-of-Life Care national program.\(^43\)\(^,\)\(^44\)

Another group reviewed certification examinations administered by nursing specialty organizations to encourage end-of-life content. The quantity and quality of end-of-life content in certification examination blueprints, specialty nursing scope and standards of practice documents, and specialty nursing core
Involvement of the certification corporations is a vital force in promoting palliative nursing care. In addition to integrating end-of-life content across multiple specialty organizations, the Hospice and Palliative Nurses Association (HPNA) has provided leadership to this evolving discipline. HPNA is the leading nursing organization supporting the development of palliative nursing. This organization provides numerous educational programs, publishes extensive educational materials, and also has a certification arm, the National Board for Certification of Hospice and Palliative Nurses (NBCHPN), that administers the specialty certification in Hospice and Palliative Nursing for registered nurses (Certified Hospice and Palliative Nurse, CHPN), for APNs (Board Certified–Palliative Care Management, APRN, BC-PCM), and for nursing assistants (Certified Hospice and Palliative Nursing Assistant, CHPNA).

### Model Nursing Programs

**Undergraduate and Graduate Education**

The coauthor of this chapter (Sheehan) has identified many important strategies in teaching palliative care to nursing students. It is important to include both didactic and clinical components in both undergraduate and graduate curriculums. An example of an undergraduate model includes content on loss, grief, and bereavement, as well as pharmacological interventions for symptom management, at the sophomore level. Content on the physiology of dying, psychosocial and spiritual issues, and the hospice model of care is presented at the junior

level, with a minimum of 12 hours with nursing faculty at an inpatient hospice facility. At the senior level, content on the dying child is covered in the Developing Families rotation.

Students tend to learn best during teachable moments. These include real events with real people. For student nurses, this usually means the clinical setting. During the clinical experience, the students work with an experienced hospice nurse. They attend the morning report and choose one or two patients with the guidance of the hospice nurse. The nursing instructor asks questions of the student and hospice nurse to facilitate learning. The instructor also meets with the students as a group early in the day to clarify the assignments for the day and to check on how the students are feeling in this environment.

The instructor brings the students together as specific learning opportunities arise, such as the death of a patient, unusual dressing changes, or pharmacological interventions. The use of reflection is a powerful tool to assist students and faculty to learn about themselves and about their practice from situations they encounter in the clinical setting and to integrate personal and professional learning experiences. For this reason, the students write a reflection on practice for each hospice clinical day. Students are prepared for the hospice experience through a group meeting with the nursing instructor early in the day. The following is an example of instructions for clinical assignments.

Undergraduate Clinical Preparation
1. You may feel exhausted by the end of the day even if you have done very little physical work. You may be emotionally drained.
2. Take time to discuss your fears and experiences with death with your clinical instructor, the hospice nurse, or your peers.
3. You may leave the unit (or classroom) at any time. Please let your instructor know how you are feeling.
4. You will be given the option to see someone who has just died to discuss physical changes in the body and the feeling in the room. You may decline this opportunity.
5. Take time to reflect on your practice.
6. Be open to learning from a variety of people, including patients, families, interdisciplinary team members, peers, and yourself.

Undergraduate Clinical Assignments
1. Listen to the full report on your unit.
3. Make rounds with the hospice nurse to see all of his or her patients.
4. Choose one or two patients with guidance from the hospice nurse.
5. Review patient/family information with the hospice nurse.
6. Assess one specific physical symptom that is most important to the patient. Use the literature to link the diagnosis with the pathophysiology. List the appropriate nursing interventions and expected outcomes. This information will be presented during the clinical conference.
7. Listen to the patient’s story throughout the day.
8. Reflection on practice: What happened today that made a difference in the way you will practice nursing?

Madonna University in Livonia, Michigan, was the first institution in the United States to offer interdisciplinary hospice education programs under the direction of Sister Mary.
Cecilia Eagan. The hospice education department, under the direction of Kelly Rhoades, PhD, offers associate’s, bachelor’s, and master’s degrees in hospice education. Students in the Master of Science in Hospice (MSH) program complete 30 semester hours of coursework and select one of five cognate specialties in bereavement, pastoral ministry, business, education, or nursing. Students may enroll in certificate programs at both the graduate and undergraduate levels in hospice education or bereavement.

The Breen School of Nursing at Ursuline College in Pepper Pike, Ohio, was the first graduate program in the United States to prepare APNs in palliative care. The Master of Science in Nursing program officially began in August 1998, under the direction of Denice Sheehan, although the first course was offered during the 1998 spring semester. The program builds on the college’s mission to provide an education based on values. Contemplation and reflection on practice are hallmarks of this program. The core curriculum of the master's program concentrates on theory, informatics, research, critical thinking, evidence-based practice, and leadership. The APN courses include pathophysiology, pharmacology, and health assessment. Students in the palliative care program also take two specialized palliative care courses and 500 hours in the palliative care practicum. Table 60–4 lists the required courses. A post-master’s certificate is offered to nurses with a Master of Science in Nursing (MSN) degree.

Table 60–5 summarizes the topical outlines for the palliative care courses in the Breen graduate program. Introduction to Palliative Care and Hospice is an interdisciplinary web-based course. It is the first course offered in the post-master’s certificate program. The content is taught in the core courses in the MSN program. This Introduction course provides an overview of palliative care with respect to history, philosophy, the interdisciplinary team model, and reimbursement mechanisms. Students have opportunities to explore personal beliefs, attitudes, and reactions to progressive illness, dying, and death. They discuss ways in which these attitudes can influence the care of people with life threatening illnesses and their families. Ethical issues are explored in relation to treatment decisions and quality of life. Spirituality is explored within a framework of individual values and beliefs. The essence of the self as the physical being deteriorates at the end of life is analyzed. Religious and cultural beliefs, traditions, and rituals are discussed as they pertain to end-of-life issues. Loss, grief, and bereavement are also explored as they relate to the terminally ill person and the family. Communication and counseling techniques are woven throughout this course. Research, case studies, and personal and professional experiences are used to emphasize key concepts. Classical literature is woven throughout this course in the form of case studies. Students participate in virtual rounds using asynchronous learning online. Virtual rounds provide the opportunity to make daily rounds at the hospice without actually being there. The nursing faculty member teaching the course makes rounds with the interdisciplinary team on day 1 to choose a patient to observe over the next 3 days. She presents the patient to the students via the online course on day 1. She returns to the hospice daily. The patient is presented to the students online with specific discussion questions as the case unfolds. Students are expected to make substantive comments supported by the literature and their clinical experiences. Their questions and comments are shared with the interdisciplinary team, and feedback is provided for the students. This technique has been found to be very beneficial to the students and the team. Most of the students in the post-master’s certificate program have extensive hospice or palliative care experience and clinical expertise. They live and work in urban and rural areas across the United States. This combination of expertise, diversity, and openness to new ideas creates complex discussions and innovative approaches to care.

In Palliative Care I, students have an opportunity to analyze personal attitudes toward progressive illness, dying, and death and compare their current analysis to that developed in earlier courses. They also continue the discussion about how these attitudes can influence the care of patients with life-threatening...
illnesses and their families. Ethical issues are explored in relation to treatment decisions and quality of life. This course integrates pathophysiology, pharmacology, psychosocial issues, and spirituality in the assessment and management of symptoms. Current research in palliative care is analyzed and applied in the clinical setting. The practicum may be taken concurrently or after Palliative Care I.

Students in Palliative Care II explore leadership roles for the palliative care APN in administration, education, consultation, and clinical practice. Quality process and measurement is presented within the framework of continuous quality improvement. The impact of economic and political factors on the delivery of palliative care in a variety of settings is analyzed. Students focus on special populations such as prisons and decide on special topics depending on the interests of the group.

During the Palliative Care Practicum, students have opportunities in the clinical area for direct contact with expert palliative care practitioners. This includes direct patient–family contact during home visits, team conferences, and clinical forums with the clinical group and the instructor. The students work with the dying and their families in the home, hospice, and palliative care inpatient facilities, hospitals, and extended-care facilities. Students meet with an assigned faculty member to tailor the practicum to meet the learning needs of the student. The students work with patients and their families through the dying process and participate in grief support groups. They keep a clinical journal, including learning objectives, personal/professional strengths identified during the practicum, and reflections on their thoughts and feelings during the clinical experience. They also participate in team meetings, research, and educational presentations to staff, patients and their families, and the community.

Another model nursing program is located at New York University (NYU) in New York City. NYU was the first institution in the United States to offer a Palliative Care Nurse Practitioner program. Under the direction of Dr. Deborah Sherman, the palliative care program builds on the core curriculum of the master’s program, focusing on theory, research, evidence-based practice, critical thinking, human development, cultural competence, community health care systems, and leadership. In addition to advanced science courses in pathophysiology, pharmacotherapeutics, and advanced health assessment, students take five specialized palliative care courses, a role development course, and 610 hours of palliative care practicums. A post-master’s certificate is an option for those individuals who already have a master’s in nursing. A summary of the curriculum is included in Table 60–6.

Schools of nursing are incorporating palliative care into existing graduate curricula as a subspecialty or focus. Vanderbilt University School of Nursing in Nashville, Tennessee, offers three options at the graduate level to prepare nurses to care for people with life-threatening illnesses and their families across the palliative care trajectory. The first is an adult nurse practitioner program (ANP) with a palliative care focus under the direction of Professor James C. Pace, DSN, MDiv, RN, ANPC-CS. Graduate nursing students complete 39 semester hours of coursework and 700 practicum hours in a variety of outpatient clinics, long-term care facilities, and hospice settings. At the conclusion of the program, students are eligible for ANP certification as well as certification in advanced practice palliative care. The second option includes joint degree initiatives leading to either the MSN/MDiv or MSN/MTS degrees offered in cooperation by the Schools of Nursing and Divinity at Vanderbilt University. Students complete individually designed programs of study in both nursing and theology, and course credit is shared between schools. Students can fulfill the 700-hour practicum requirement in the school of nursing and satisfy part of the field work credit required by the...
divinity school. A third option at the graduate level includes two elective courses, “Research in Religion and Health” and “Health and Salvation Themes,” which are cotaught by Dr. Pace and Dr. Leonard M. Hummel, Assistant Professor of Pastoral Counseling and Pastoral Theology at The Vanderbilt Divinity School.

Continuing Education

Although palliative care education in undergraduate and graduate programs provides an important foundation for the nursing profession, continuing education is also needed to reach nurses already in practice. Continuing education is needed to reach nurses in all settings involved in end-of-life care. A wide range of methods, including conferences, self-study courses, computer- and web-based approaches, and simulated clinical experiences, are needed.

In 1999, the AACN and the City of Hope National Medical Center initiated collaboration to develop a national education program on end-of-life care for registered nurses. This national project, the End-of-Life Nursing Education Consortium (ELNEC), followed the efforts by the medical profession to address end-of-life care through the Education for Physicians in End-of-Life-Care (EPEC) program. The ELNEC project was funded by The Robert Wood Johnson Foundation (RWJF). The nine components of the ELNEC curriculum included Nursing Care at the End of Life, Pain Management, Symptom Management, Ethical/Legal Issues, Cultural Considerations, Communication, Grief/Loss/Bereavement, Achieving Quality Care, and Care at the Time of Death. The ELNEC project was developed as a 3-day training program that included many educational modalities such as lectures, role-plays, small-group work, case discussion, and other experiences. The “Train-the-Trainers” model was used: individuals attending the ELNEC course were expected to gain knowledge of the content as well as skills in teaching the content. A very extensive application process was designed to ensure that ELNEC participants had established goals for their dissemination of the curriculum before attending the course and had the support of the Dean or administrators to ensure success in their implementation. The RWJF funding provided eight initial courses targeted for 100 participants per course. These courses included five focused on faculty teaching in undergraduate nursing programs and three targeted for continuing education providers. The five training programs were held in 2001 and 2002 and addressed continuing education providers and nurse educators from hospices, palliative care programs, and community agencies. The components of the ELNEC program are listed in Table 60–7.

The ELNEC project subsequently received funding from the National Cancer Institute to reach educators in graduate nursing programs for an APN version of the curriculum, and in 2003 the project received funding to initiate a curriculum.

specific for oncology nurses. The oncology project is conducted in collaboration with the Oncology Nursing Society (ONS). From 2001 to 2003, the ELNEC investigators developed and tested a pediatric version of ELNEC, with the first national training program held in August 2003. Several publications have described the ELNEC project and its curriculum care.46–48 The reader is directed to the ELNEC website at http://www.aacn.nche.edu/elnec/ for additional information.

Continuing education opportunities are offered by specialty nursing organizations. All of these organizations hold annual conferences and publish palliative care articles in their journals, many with continuing education credit. In addition, the HPNA offers teleconferences online for nurses and nursing assistants. The ONS hosts an annual Institute of Learning and a biennial Cancer Nursing Research Conference. Virtual Sessions uses streaming video to showcase instructional sessions from the ONS Congress and Institutes of Learning. Sigma Theta Tau International offers online sessions in end-of-life care.

**Future Directions**

Clearly, there is much work to be done to advance nursing education in palliative care. Improving the care of patients will be accomplished only when nursing education within undergraduate, graduate, and continuing education is improved and supported by research. Progress over the next decade will require collaboration internationally and a close commitment by nursing education, research, and practice. Collectively, these efforts can advance the profession of palliative nursing and dramatically improve care at the end of life.

**Evaluation of Palliative Care Education**

Evaluation of education is a challenge in any program and for any content, but it is a special challenge in palliative care education. As the core content of this education evolves, so will the methods of evaluation. There is a need for standard knowledge assessment measures, as well as means for evaluating clinical skills, decision-making, and a broad range of physical, psychosocial, and spiritual care skills necessary in palliative care.49–51 New technologies, such as web-based teaching and evaluation tools, will be important resources for educators.

**REFERENCES**

Nursing Research

From the cellular to the social level, much remains to be learned about how people die and how reliably excellent and compassionate care can be achieved. Important, unanswered questions exist about the fundamental physiological mechanisms of the symptoms that cause so much suffering among dying patients and about the kinds of interventions that will relieve these symptoms. Basic epidemiological information on how people die is limited, and the influence of attitudes and beliefs on people's experience of dying and on caregiving practices is little charted. In addition, a better understanding of the reasons for the inadequate application of existing knowledge would help in identifying organizational, economic, and other incentives for the provision of accessible, effective, and affordable care at the end of life.—Field and Cassel (1997)

The words of Field and Cassel, from a 1997 report of the Institute of Medicine (IOM) on improving care at the end of life, capture the breadth of palliative care research. Uniform agreement across disciplines and among authors confirms the paucity of palliative care research and the resultant absence of a scientific foundation for practice, which affects the care of patients at the end of life.2–7 Better patient care depends on both the quantity and the quality of palliative care research.

A major component of palliative care research is nursing research. The patient experience of dying is an ideal health care concern appropriate for nursing inquiry.8,9 Because nurses are concerned with patient responses to illness, the physical, psychological, social, and spiritual responses of the terminally ill and their families are prime areas for nursing research.

The ultimate goal of nursing research, and indeed of nursing knowledge, is to improve patient care. Palliative care offers a rich opportunity for research to directly influence patient care in areas such as symptom management, psychological responses to a terminal illness, and the family caregiver experience of terminal illness.10–14

Some of the earliest contributions to palliative care research were made by nurses. Pioneering work by Jeanne Quint Benoliel and others raised awareness of deficiencies in care of the dying.15,16 Early descriptive studies documented the influence of nursing attitudes and beliefs about death on the care provided to patients.

From the earliest studies in the 1960s to the “awakening” of attention to palliative care in the late 1990s, research in palliative care has been limited. Nurse investigators have addressed aspects of end-of-life care such as pain management, bereavement, settings of care, and care of special populations such as patients with the acquired immunodeficiency syndrome (AIDS). However, there has been a lack of cohesive commitment to palliative care nursing research.

In 1997, the National Institute of Nursing Research (NINR) led an initiative regarding end-of-life care research across several institutes of the National Institutes of Health (NIH).
Specific recommendations of an NINR-sponsored conference on end-of-life care are described later in this chapter.17 NINR has been designated as the lead institute at the NIH in the area of end-of-life care. It is appropriate and commendable that the NINR is providing leadership at the NIH in this research agenda.

As has been true in other areas of health care, the research agenda has lagged behind the demands of clinical practice and education. Hospice programs and palliative care settings face increased demands for improved end-of-life care with little scientific knowledge to guide clinical decisions. Nursing schools have begun to develop undergraduate and graduate courses in palliative care, and some have launched degree or certificate programs in palliative care, again with limited research as a scientific foundation of their programs. Obviously, development of a solid research agenda and support of nursing science in palliative care are overdue.

Goals of Palliative Care Research

The goals of palliative care nursing research are similar to goals of other areas of nursing inquiry. Nursing research serves multiple functions, including quantification of information, discovery, description of phenomena, quality improvement, and problem-solving.9 Quantification is accomplished through descriptive studies or through epidemiologic approaches. For example, there is a need to quantify the symptoms present in terminal illness, as well as their severity and impact. The field of palliative nursing care is relatively unexplored, and therefore there is great opportunity for discovery. What are the greatest needs of terminally ill patients and their family caregivers? What is the unique role of nursing within the interdisciplinary team?

The subjective nature of terminal illness and the existential experience of dying require research methods that describe phenomena. Death, as a subject that has been avoided in society, is still a relatively unknown aspect of life. On a more specific level, palliative care is also a field that would benefit tremendously from research linked to quality improvement. Numerous reports have identified serious deficits in end-of-life care, and efforts to improve the quality of end-of-life care will undoubtedly benefit from research. Finally, a major goal of palliative care research should be basic problem-solving. What drugs are most beneficial for dyspnea or agitation? What is the best treatment for pressure ulcers in a dying patient? What education best prepares family caregivers for signs and symptoms of approaching death?

Ethical and Methodological Considerations in Palliative Care Research

There are many unique aspects of research in palliative care. The multidimensional nature of care at the end of life and the vulnerability of the population are but two examples of factors that pose special challenges to this area of research.

The challenges of nursing research in palliative care should be prefaced by a discussion of the benefits. Although even the mention of conducting research with dying patients and their burdened families immediately creates concerns, there are in fact many benefits to participants. Participating in research, even at this most vulnerable and sensitive time of life, provides the opportunity for research subjects to contribute to others. Research participation often provides an opportunity to derive meaning from illness and to feel that one’s suffering will provide benefit to others.8,18

In the authors’ research at the City of Hope, involving numerous studies in sensitive areas such as pain, quality of life, and fatigue, positive feedback has consistently been received from research subjects. Patients and family caregivers often have thanked the researchers for studying these topics, which they perceive to be of great importance. Subjects have also frequently related that completing written instruments or participating in interviews provided a mechanism for communicating needs that had not previously been voiced.

However, research in palliative care is very challenging and includes many obstacles. Nurses are often conflicted in balancing the role of clinician with that of researcher. For example, in conducting research related to pain in terminally ill cancer patients, the authors have often had to carefully balance these roles. Identifying a patient with severe pain has often meant that the patient’s participation in a study must be ended in order to seek treatment for the pain. Research must always respect the more important ethical consideration of protecting the patient’s well-being.18

Seeking informed consent in rapidly declining, weak patients is a challenge, as is the need to constantly protect patient and family autonomy. Subjects in palliative care research may feel obligated to participate in research, particularly if they have been the recipients of good care. Although all patients in palliative care are considered vulnerable, certain subgroups, such as the cognitively impaired, the poor, and the elderly, are of special concern.19–23

The sensitive nature of palliative care research provides inherent challenges. The areas of concern at the end of life are highly emotional and may invoke heightened distress. Exploring areas such as grief, fears, spiritual concerns, family conflict, and other common dimensions of terminal illness is highly challenging. Participation in research can bring to the forefront previously undisclosed problems. The authors have found, in their research experience, that palliative care research necessitates highly skilled research staff. Collecting data from palliative care subjects is very different from research in healthy or chronically ill subjects. Research nurses in palliative care studies must be clinically competent, highly skilled nurses equipped to balance the rigor of research with extreme sensitivity.

Palliative care research, perhaps more than any other field of inquiry, must carefully weigh subject burden. The time required of research subjects in palliative care, a precious commodity for those with terminal disease, must be carefully protected. Special consideration must be given to selection of research instruments and procedures to minimize subject burden.
A useful resource for nurses researchers in palliative care is the “Tool Kit” project, supported by a grant from the Robert Wood Johnson Foundation to researchers at the University of Rhode Island. This project reviewed and compiled a list of research instruments recommended for use in palliative care. The tool kit is available online at http://www.chcr.brown.edu/web-pubs.htm#top (accessed March 1, 2005).

Subject attrition is another common problem area in palliative care research. Higher attrition has serious implications when determining sample sizes and also has budget implications. This problem area becomes an even greater concern in longitudinal studies, which are a definite need in palliative care.19–23 New approaches to handling data are needed to improve data analysis.

Palliative care research also necessitates diversity in research methods. The authors’ experience has been that a combination of qualitative and quantitative approaches is needed.24 Qualitative approaches are especially important in descriptive studies. Appendix 61–1 includes examples of two qualitative nursing studies that serve as models for application of these methods for palliative care research. Quantitative approaches are essential when studying symptoms, their frequency and nature, and response to treatment.

The authors also have found that nursing research in palliative care is greatly enhanced by interdisciplinary collaboration. The problems studied are multidimensional and are best defined from the viewpoints of various members of the health care team. Participation from colleagues in psychology, theology, social work, and other disciplines has enhanced our work considerably.

A final special consideration in palliative care research is the importance of including family caregivers. Terminal illness is a shared experience, and including family caregivers as subjects enriches the benefits to be derived from the research.10,12,13

Table 61–1 summarizes some of the key challenges of conducting palliative care research. Advancement of the nursing profession in palliative care will require attention to overcome these obstacles.

### A Research Agenda in Palliative Nursing

The IOM report identified priority areas for end-of-life care research, including pain, cachexia-anorexia-asthenia, dyspnea, cognitive, and emotional symptoms. Also addressed was the need for social, behavioral, and health services research. Nursing as a profession has much to contribute to each of these identified priorities.8,9

There is a tremendous need to bring together nurse researchers and nurse clinicians in palliative care. Historically, few nurse researchers have focused on palliative care; likewise, few expert clinicians in palliative care have had opportunities or expertise in research.

Although an exhaustive review of research methods or grant writing is not possible in this chapter, a few comments are worthy of attention. Palliative care clinicians are encouraged to seek collaboration with nurse researchers to initiate clinically relevant and scientifically sound studies. Another key issue of advice is to begin small. Conducting small pilot studies is an essential foundation to launching larger-scale studies. Potential sources for funding are found in Table 61–2.

Table 61–3 includes an example of criteria used in evaluating small-scale research projects. These criteria, adapted from...

<tbody>
<tr>
<td>Research Proposal Evaluation Criteria</td>
</tr>
</tbody>
</table>

**Abstract**
- Abstract accurately reflects the proposal.
- Abstract includes problem statement and purpose.
- Abstract summarizes key variables, sample, and methods.

**Study aims, hypotheses, or study questions**
- Clearly stated
- Hypotheses or study questions are consistent with the study aim.
- All proposed study procedures and data to be collected are encompassed.

**Significance of the study**
- The research contributes to the science of palliative nursing care.
- The research has the potential to lead to further investigation.
- The research offers a unique contribution to the literature.
- The research is clinically relevant to end-of-life care.

**Literature review**
- Relevant and current literature is reviewed.
- Literature primarily includes research rather than opinion.
- Literature is critiqued, synthesized, and analyzed.

**Conceptual/theoretical framework**
- Framework identified is appropriate to the study and consistent with study questions and methods.
- Framework is consistent with the philosophy of palliative care.

**Procedures**
- The procedures are feasible.
- Procedures include methods for training and supervision of personnel.
- Procedures provide sufficient description of precisely what will be required of subjects.

**Data analysis**
- Specific statistical procedures are identified.
- Analysis is appropriate for the type of data and study design and answers the study questions.
- Computer facilities and consultation are described.
- Investigator has sought consultation if necessary in preparing the proposal.

**Human subjects considerations**
- Institutional Review Board approval is given or documentation of pending review is given.
- The investigator is clearly aware of the impact of participation in the study on the subject.
- The investigator addresses concerns regarding length, intrusiveness, and energy expenditure required.
- The investigator has acknowledged special considerations of terminal illness.

**Investigators and research team**
- Consultation is available for the less experienced researcher.
- The role of co-investigators or consultants is established.

**Overall**
- The proposal strictly adheres to format restrictions and page limitations

the Oncology Nursing Foundation, depict the essential elements of a research proposal. Many professional organizations provide small grant support to novice investigators. Table 61–4 includes some general tips for preparing a research proposal.

Another useful guide for nurses initiating research proposals is included in Table 61–5. This includes the review considerations used by grant reviewers at the NIH. The five criteria of significance, approach, innovation, investigator, and environment can serve as a useful guide in designing research proposals.

Several initiatives have begun to establish an agenda for palliative care research. Topics frequently identified as priority topics for palliative care research include pain, symptom management, epidemiological studies of terminal illness, family caregiver needs, bereavement, cultural considerations, spiritual needs, and health systems considerations such as costs of care.

At the City of Hope, we have developed a framework of nine areas of palliative nursing care that is used in our nursing education efforts (see Chapter 59). Table 61–6 includes a summary of these nine topic areas, with examples of potential research that is needed.

Another excellent resource for identifying future areas of palliative care research comes from the conference convened by the NINR described previously. An excerpt of the Executive Summary from this NIH research workshop, which focused on symptom management in terminal illness, is included as Appendix 61–2, together with the specific recommendations from that conference, which identified research needs regarding the symptoms of pain, dyspnea, cognitive disturbances, and cachexia.

Summary

Advances in the care of patients and families facing terminal illness is contingent on advances in palliative nursing research. Control of symptoms, comfort for families, and attention to psychosocial and spiritual needs will improve when nurse clinicians have a stronger scientific foundation for practice. Research will require collaboration with other disciplines and unity of nurse clinicians and researchers.

General Tips for Preparing Research Proposals |
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>• Grant writing is not a solo activity—seek consultation and collaboration from others. Seek opportunities to involve clinical palliative care settings, such as hospices, in nursing research.</td>
</tr>
<tr>
<td>• Have your proposal reviewed by peers before submitting it for funding. A proposal submitted for funding is generally the product of numerous revisions.</td>
</tr>
<tr>
<td>• Follow the directions in detail, including margins, page limits, and the use of references and appendices. Communicate directly with the funding source to clarify any directions you are unsure of.</td>
</tr>
<tr>
<td>• State ideas clearly and succinctly. Word economy is essential to a fine-tuned proposal.</td>
</tr>
<tr>
<td>• Use high-quality printing and use a good-quality copier. Give attention to spelling and grammar.</td>
</tr>
<tr>
<td>• Plan ahead and develop a time frame for completing your grant. Avoid the last-minute rush that will compromise the quality of your proposal. It is better to target a future deadline for submission than to compromise your score due to a lack of time for preparation.</td>
</tr>
<tr>
<td>• Use appendices to include study instruments, procedures, or other supporting materials. Adhere to funding agency criteria, but maximize the opportunity for a complete proposal.</td>
</tr>
<tr>
<td>• Include support letters from individuals who are important to the success of your study. This includes medical staff, nursing administration, consultants, and co-investigators.</td>
</tr>
<tr>
<td>• Do not hesitate to contact experts in your subject area to seek their input. They are often able to review your work and direct you toward related instruments or literature.</td>
</tr>
<tr>
<td>• Start small. Successful completion of a pilot project is the best foundation for a larger study. Efficient use of small grant funding is influential when seeking larger-scale funding for major proposals.</td>
</tr>
<tr>
<td>• Be realistic. Design research projects that can be realistically accomplished within the scope of your other responsibilities and the limitations of your work setting.</td>
</tr>
<tr>
<td>• Keep focused on the patient. Design and implement research that is relevant to patient care and improves quality of life at the end of life for patients and families.</td>

Two Examples of Qualitative Nursing Studies

Interaction Patterns Between Parents with Advanced Cancer and Their Children

Denice Sheehan, RN, MSN
Doctoral Dissertation, University of Akron and Kent State University

The purpose of this project is to develop a theoretical framework to describe interaction patterns between parents with advanced cancer and their children and to identify strategies that parents use to prepare their children for their lives after the parent's death. Most of the published literature about parents with cancer and their children focuses on psychosocial and emotional distress, functional changes within the family, and economic burdens. Few researchers have considered the end of life as an opportunity for growth and healing. Studies are needed to understand the process by which parents with advanced cancer interact with their children, a complex psychosocial process. Therefore, grounded theory methodology is used to develop a theoretical framework. A minimum of 30 participants are recruited. Parents with a diagnosis of advanced cancer who have children younger than 18 years of age are recruited from cancer centers, hospice programs, and support groups. The spouses and children of these informants are also invited to participate, because they are able to offer important perspectives on the ways in which the parent and child interact that may be unknown to the parent with cancer. The primary investigator conducts semi-structured interviews in a private room at the cancer center, hospice facility, or support group site. Findings from this study facilitate nurses to provide optimum support and communication to parents who are faced with the challenge of parenting children while living with their own impending death. Identification of these processes may also inform the development of nursing interventions aimed at assisting parents and children coping with advanced cancer.

Meanings and Uses of an Expressed Desire for Hastened Death in People Living with Advanced Cancer

Nessa Coyle, PhD, RN, FAAN
Memorial Sloan-Kettering Cancer Center

An exploratory qualitative study, using an interpretive phenomenological approach, explored the impact of advanced cancer on seven individuals living with the disease. These individuals had received the majority of their care at an urban research cancer center and had expressed, at least once, a desire for hastened death. The hypothesis was that by providing an individual the space to talk about his or her lived experience through a series of in-depth, semistructured interviews, the grounds for the expression of desire for hastened death for that individual would be uncovered. A total of 25 interviews were held.

Through an interpretive analysis of the narratives of the seven individuals, four themes and two overarching themes were identified. The four themes were “Listen to Me,” in which the participants described their relationships to the health care system; “Who Am I Now and Where Do I Belong,” in which the participants dealt with changes in themselves and their place in the world; “Up Against the Wall—There Is No Way to Live with Such Pain,” in which the participants described their experiences with excruciating or chronically uncontrolled pain; and “The Existential Slap,” the moment of realization by the participants that death was imminent. The two overarching themes were “The Hard Work of Living in the Face of Death” and the “Existential Paradox”—that is, that although the participants had expressed at least once a desire for death, what they were seeking was life.

The overarching themes appeared to capture the paradox of an expressed desire for hastened death and informed the interpretive analysis of the narratives—that an expressed desire for hastened death in these participants was a tool of communication reflecting:

1. A manifestation of the will to live
2. That the dying process itself was so difficult that an early death was preferred
3. That the immediate situation was untenable and required immediate action
4. That a hastened death was an option to extract oneself from an unendurable situation
5. A manifestation of the last control the dying can exert
6. A way of drawing attention to “me as a unique individual”
7. A gesture of altruism
8. Manipulation of the family in order to avoid abandonment
9. A despairing cry depicting the misery of the current situation

The overall interpretation was that an expressed desire for hastened death in these individuals was not a literal request for death but a tool of communication to get needs met.

NIH Research Workshop on Symptoms in Terminal Illness—Executive Summary

Patients at the end of life experience many of the same symptoms and syndromes, regardless of their underlying medical condition. Pain is the most obvious example, but others are difficult breathing (dyspnea), transient episodes of confusion and loss of concentration (cognitive disturbances and delirium), and loss of appetite and muscle wasting (cachexia), as well as nausea, fatigue, and depression. Taken together, these
and other symptoms add significantly to the suffering of patients and their families, and to the costs and burden of their medical care. Yet in many cases the symptoms could be treated or prevented.

Pain, for example, is a multibillion-dollar public health problem in the United States. More than half of all cancer patients experience pain related to their disease or its treatment. Similarly, half of all cancer patients and 70% of all hospice patients experience shortness of breath in the last weeks of life. Yet dyspnea remains underdiagnosed and undertreated. Forty percent of all patients experience cognitive disturbances during the final days of life, and high numbers of terminally ill patients experience cachexia regardless of their primary disease. Significantly, these symptoms occur not in isolation but in clusters, with most patients experiencing combinations of symptoms that vary greatly in their prevalence and severity, as well as in the suffering they cause.

Basic research has improved understanding of the underlying mechanisms of symptoms that are commonly experienced at the end of life, particularly with respect to pain. Clinical research has in some cases translated this knowledge into new drugs and other interventions that can effectively relieve or prevent these symptoms, even if the underlying disease cannot be cured. At present, however, there remain a number of important gaps in knowledge.

Clinical care would benefit from an integrative, multidisciplinary research initiative that brings basic and clinical researchers together to address the constellation of symptoms at the end of life. The following areas should receive priority:

- **Epidemiology**—There is a need for better data on the incidence and combinations of symptoms that are experienced at the end of life in specific populations. Epidemiological data will demonstrate the magnitude and costs of the problem and suggest specific topics for basic and clinical research.

- **Basic research**—Additional research is needed on the mechanisms and interactions of these symptoms, including biochemical, neuronal, endocrine, and immune approaches. The possibility of common factors, mechanisms, and pathways across different symptoms should be examined. There is also a need for research on the mechanism of action of successful therapies, with particular attention to the role of opioid receptors. This research could lead to therapies that are better targeted and more selective in their action, and thus produce fewer side effects.

- **Clinical research**—Because these symptoms have multiple determinants, and occur in clusters, successful interventions will also be multifactorial, including behavioral as well as pharmacological approaches. Combination therapies and off-label drugs should be explored. Researchers should be alert to differences in outcome based on age, gender, and underlying disease. Interventions to mobilize psychosocial and spiritual resources may be of help in mediating the perception and interpretation of symptoms. The goal of research should be to test a wide range of interventions that could be successfully implemented in the home or hospice, as well as in the hospital.

- **Methodology**—Researchers need better tests for diagnosing and assessing the level of severity of these symptoms, as well as for monitoring the effectiveness of interventions. Standardized terminology and definitions of symptoms should be established. Particular attention should be paid to validating subjective and nonverbal measures. Better data and tools are also needed for evaluating outcomes, in order to determine costs and strengthen accountability for the quality of care at the end of life. It is important to develop and use measures that reflect the subjective experience of the effects of symptoms on quality of life.

Research is also needed on the ethical issues that may be barriers to research at the end of life, including the needs and protection of vulnerable populations, especially the role of privacy during this important phase of life. Attention must be paid to community and individual preferences about the relative value of symptom management at different points in the dying trajectory, and to the development of comprehensive strategies for early detection and treatment of the full range of symptoms at the end of life—an approach that will reduce costs as well as burdens, while preserving the patient’s dignity and quality of life.

**Recommendations for Research on Specific Symptoms**

The following preamble for the recommendations reflected the consensus of the entire workshop:

To adequately address symptom control in the terminally ill, an important first step is to invest resources in the development of new methodologies for assessing symptoms and evaluating treatments. These tools will allow us to elucidate the extent of the problem and to set national priorities to improve quality of life for those facing life-limiting illness.

**Pain**

1. **Epidemiology**—There is still a great need for epidemiological data on the incidence and types of pain at the end of life. Research in this area will provide direction for researchers regarding what specific topics should be tackled next.

2. **Treatment**—There is a clear need to discover new drugs for the treatment of pain, including analgesic combinations. Neuropathic pain, because of its incidence and burden, should be a particular priority. There should also be studies of the relationship between disease, pain, and suffering at the end of life.
life, which would also include psychosocial mediators. Clinical Trials Groups should be developed to study promising interventions.

3. Measurement—Methods should be developed for collecting valid data on pain in the home, in nursing homes, and so on, possibly using telephones or computer technology. Measurement of other outcomes of subjective experience, such as the suffering caused by pain, should also be developed and utilized.

**Dyspnea**

1. Epidemiology—What are the incidence and impact of dyspnea in different populations? There is some information about dyspnea in patients with cancer or chronic obstructive pulmonary disease (COPD), but almost none about patients with cardiac disease or other terminal conditions.

2. Mechanisms—Relatively little is known about the various determinants of dyspnea, including respiratory muscle strength, exercise capacity, respiratory controller, gas exchange, and psychosocial factors. Neurobiological models, like those developed for pain, will be useful, but the overall approach must be integrative. The determinants are almost certainly multifactorial, necessitating multidisciplinary strategies.

3. Measurement—Research is needed to refine available instruments and develop new ones for measuring both the causes of symptoms and the effects of treatments. There is at present no standardized approach for assessing the degree of dyspnea in a given disease (e.g., chronic vs. acute, COPD vs. cancer). The goal would be to formulate guidelines for optimal assessment, which would point to optimal treatment.

4. Treatment—A number of potential treatments are available, but there is little information on their relative effectiveness. Particular attention should be given to the choice and timing of anxiolytics, phenothiazines, oxygen, opiates, and exercise. Attention should also be given to the timing and management of terminal weaning (removal of ventilation), including the role of families.

The collaborative and integrative nature of this research is well suited to sponsorship and funding by NIH. It would be useful, for example, for the various NIH Institutes to sponsor a series of joint workshops that would characterize the clinical experience and impact of therapies on dyspnea in diseases other than lung cancer.

**Cognitive Disturbances**

There is a considerable amount of epidemiological data on delirium already, and although it might be useful to gather additional information on specific patient populations, this symptom is known to be under recognized and under treated. Consequently, the research priorities in this symptom area are as follows:

1. Measurement—Research is needed to enhance the recognition of delirium in different treatment settings (homes, hospices, hospitals), including common diagnostic criteria and terminology. Also needed are better instruments to describe and rate the severity and course of episodes of delirium. This research will lead to a better understanding of the phenomenology of delirium—its signs, patterns, and subtypes—which in turn should produce benefits in terms of newer, more sensitive, and more effective treatments.

2. Treatment—Two aspects of treatment research deserve simultaneous attention. First, there should be randomized, placebo-controlled trials to systematically assess the efficacy of currently available therapies as well as emerging approaches, including both pharmacological and nonpharmacological strategies. Second, there should be research on the relation between the mechanism of action of these therapies and the underlying pathophysiology of delirium. In both cases, studies should include both random populations and populations with delirium of homogeneous etiology.

3. Epidemiology—Finally, there is a need for additional research on the interactions between delirium and other symptoms at the end of life.

A concurrent policy issue that must also receive priority attention is the need for guidelines for research in patients who are incapable of giving informed consent because of serious medical illness.

**Cachexia**

1. Epidemiology—High priority should go to epidemiological studies of anorexia-cachexia, to establish the magnitude of the problem, its impact on the patient and family, and its costs to society. However, it is important that cachexia not be studied in isolation from other symptoms. If the ultimate goal of cachexia research is prevention and early intervention, then it would be useful to conduct studies that examine the epidemiology of several related symptoms (e.g., pain, dyspnea, delirium) at an earlier stage in their development.

2. Mechanisms—Basic and clinical research on cachexia should be done in parallel. Basic research should emphasize the interactions among multiple underlying pathophysiological mechanisms, both central and peripheral, including biochemical, neuronal, metabolic, endocrine, and immunological.
Research is also needed on the varying clinical manifestations of these mechanisms, both neuropsychiatric and gastrointestinal. This calls for a multidisciplinary approach.

3. Treatment—Similarly, because it is unlikely that any single therapeutic intervention will be successful, clinical research should emphasize multiple combination therapies that include nutritional, pharmacological, and nonpharmacological components. Combination therapies should be evaluated for their effects on other symptoms such as pain, dyspnea, and delirium. Particular attention should also be paid to differences in outcome based on age, gender, and underlying disease. In considering drug trials, NIH should concentrate on studies that would not otherwise be funded by drug companies.

Given the wide range of mechanisms and therapeutic strategies in cachexia, it would be useful to convene a preliminary, integrative workshop that would include both basic and clinical researchers.

Cross-Cutting Recommendations

Methods issues that need to be addressed in all four symptom areas include the following:

1. Statistical handling of missing data.
2. Proxy reporting for subjective symptoms.
3. Outcome measures that indicate quality care.
4. Ethics issues are also important. What are the barriers to research at the end of life, including the needs and expectations of vulnerable populations? What are community and individual preferences with respect to symptom management of dying persons?
5. Economics questions include the direct and indirect costs and burdens of symptoms.

Delivering Palliative Care in Challenging Settings and to Hard-to-Reach Populations

I told him “I love you. Thank you. You can go. I love you.” And then he died. It was perfect. It was everything we had done. It was like music ending.—Family member of a patient served by The Comprehensive Care Team, a project of the University of California San Francisco School of Medicine

Key Points
- Although high-quality hospice programs represent the gold standard of palliative care, they are often underutilized by or unavailable to special patient populations, prompting consideration of new models of delivering palliative care.
- A broad quality improvement strategy emerged in the late 1990s, including new delivery models that offer palliative care simultaneously with cure-oriented care to patients and families.
- There are discernible programmatic elements, clinical components, and educational strategies that lead to strong, successful, sustainable palliative care programs.
- Preliminary data from The Robert Wood Johnson Foundation’s Promoting Excellence in End-of-Life Care demonstration projects suggests that the concurrent provision of life-prolonging care and palliative care is feasible, clinically effective, embraced by patients and families, and associated with system efficiencies.

High-quality hospice programs represent a gold standard for comprehensive care for people who are dying. In the United States, hospice use has increased among cancer patients and other defined patient groups. However, even the most innovative hospice organizations meet barriers in attempting to serve patient populations in acute care hospitals, particularly academic research and teaching hospitals, and in highly technical environments such as renal dialysis units and intensive care units. Hospice is also challenged to deliver care in geographically isolated rural communities and for socioeconomically isolated populations served by “safety net” facilities, such as impoverished inner-city residents, military veterans, and prison inmates.

A Strategic Direction

Clinicians, health care administrators, payers, and consumers all have vested interests in redesigning health care systems to respond to the suffering experienced by patients with advanced, incurable illness. Recognizing the need in the United States for innovative models for delivering palliative care to these underserved patient populations, during the late 1990s clinicians and researchers embarked on strategic efforts to improve care through the end of life, supported by government and private philanthropies. Cognizant of the complexity of achieving necessary systemic and cultural change, they employed a multifaceted approach that simultaneously targeted a range of leverage points (Table 62–1).

This broad quality improvement strategy has at its heart a commitment to position patients and families at the center of the health care goals. Components of this strategic approach include efforts to elucidate clinical practice standards and domains of quality for palliative care, as well as clinician training curricula and continuing education that encompasses the full breadth of patient and family experience and palliative care.
care practice. The strategy also includes development of measurement tools and methodologies applicable to clinician skills, quality of care, and health service delivery that are capable of not only distinguishing the adequate from inadequate, but also the excellent from the merely mediocre. These measurement tools can be applied to performance and outcomes evaluation and to relevant oversight, certification, and accreditation processes. The strategy further calls for research and development of demonstration projects to build and assess innovative models of care delivery. In order for advances in quality and delivery of care to be successfully applied, changes in public policy, health care regulations, and reimbursement are needed. The strategic approach entails public education to raise awareness, along with citizen advocacy and consumer pressure supported by meaningful data on access, quality, and costs of care.

This chapter focuses on the research and development component that creates and tests new models of care delivery, drawing on the experience of a variety of innovative service delivery models developed with support from The Robert Wood Johnson Foundation’s Promoting Excellence in End-of-Life Care program. These demonstration projects offer programmatic prototypes for delivering palliative care to hard-to-reach patient populations and in challenging clinical settings. These models are designed to offer seriously ill patients and their family members coordinated and continuous attention to their psychosocial and spiritual needs, as well as their physical needs, provided by a skilled team. These characteristics are key principles of palliative care.1–3

Unmet Expectations and an Unnecessary Dichotomy

Recent studies indicate an incongruity between what seriously ill people feel is most important and what the current American health care system provides. In qualitative research involving seriously ill patients and recently bereaved family members, as well as experienced clinicians, Steinhauser and colleagues found that patients and their families value pain and symptom management, clear decision-making, preparation for death and life completion, a sense of contributing to others, and affirmation of the patient as a whole person. Similarly, a qualitative study by Wenrich and associates concluded that patients and families value clinicians who talk in honest, straightforward ways about their patients’ conditions and who can sensitively break bad news without shirking discussions about death. They want clinicians who encourage questions and are sensitive to when patients are ready to talk about death. Although these values and expectations are reasonable, they are not consistently achieved.

Thirty years ago, life-prolonging and palliative treatments seemed clearly distinct. Advances in the physiology and pharmacology of treatment, particularly in the fields of oncology, cardiology, pulmonology, and neurology, have progressively blurred distinctions between treatments intended to prolong life and those intended to improve a patient’s comfort and quality of life. The familiar diagrams in Figure 62–1 illustrate, first, the current dichotomy between life-prolonging and palliative care that results in a sequential model of care, wherein palliative care is initiated only when curative treatment is abandoned. There is broad agreement that a concurrent approach, with palliative care introduced at diagnosis and extended through the course of treatment, decline, death, and grief, would better respond to the needs of seriously ill patients and their families.

In theory, concurrent care should align health service delivery with contemporary clinical realities and the real needs of chronically ill patients and their families. New models of delivering palliative care are emerging to build and test this vision.

Promoting Excellence in End-of-Life Care: Building Models to Translate Theory into Practice

The Robert Wood Johnson Foundation’s Promoting Excellence in End-of-Life Care program was created in 1997 to provide grant support and technical assistance to clinician-researchers for development of innovative ways of extending comprehensive, patient- and family-centered palliative care to those living with progressive, incurable conditions, regardless of diagnosis, prognosis, age, socioeconomic status, or venue of care. Promoting Excellence sought to identify patient populations and clinical settings in which hospice care was underutilized or unavailable. Setting the best hospice programs and care as gold standards, the Promoting Excellence program intended to extend palliative care upstream in the course of illness, concurrent with ongoing life-extending care. Many of the projects collaborated with local hospice programs, and most projects developed a continuum of services that included referral to hospice.

The more than 25 projects were awarded Promoting Excellence in End-of-Life Care grants, representing a broad range of patient populations and contexts of care. This diverse array of demonstration projects involved four university cancer centers, tertiary care pediatric hospitals, critical care units in four academic medical centers, a regional set of renal dialysis clinics, and hospice and home health agencies within highly penetrated managed care environments. Several programs served inner-city residents, and others served rural and frontier communities, including projects focused on Native American and Alaska Native populations. Other programs were designed for elderly residents in nursing homes, patients with dementia cared for in a geriatric specialty clinics, and hospice programs based in penitentiaries in four states.

The purpose of building prototypical programmatic models was to determine the feasibility of providing palliative care within these challenging contexts of care and to these patient populations. Demonstration projects represent applied research, the translation of theory into practice, which provides tangible evidence of what is possible—and what is not—from the perspective of provider organizations, clinicians, and the people being served. Prototype projects generate valuable information regarding whether and how well services are valued by the intended population. Successful health service prototypes have potential to stimulate improvements beyond local systems and communities, raising collective expectations and challenging administrators, health planners, and public policy-makers to consider new approaches to existing problems and to aim for higher outcomes than they otherwise might have thought possible.

Elements of Successful Delivery Models

Analysis of prototypical models indicates that there are discernible elements that, when included in the program design, lead to strong, successful, and sustainable programs for delivery of palliative care (Table 62–2). Clinician-researchers have learned that innovative palliative care programs must be anchored in the institution’s and local health system’s core mission and that aligning the program with the organizational mission results in increased receptivity for the initiative by...
institutional decision-makers. Programs must be manageable in scope, allowing nascent initiatives to achieve early successes and earn support from recognized leaders in both clinical and administrative realms. Palliative care teams are more readily integrated into the institution’s clinical practice if they are able to improve the workflow of time-pressured clinicians, assisting them in addressing patients’ and families’ psychosocial needs and the personal ramifications of their patients’ life-compromising illness. Successful interdisciplinary teams are able to embed palliative care into routine operations and have authority to carry out their recommendations and interventions for patient care. They earn the confidence of colleagues by skillfully and reliably caring for complex cases.

In addition to focusing on clinical aspects of integrating palliative care and cure-oriented treatment, sustainable programs develop business plans that address economic aspects of operations and service delivery. They also develop communication plans that convey cohesive messages, including salient data to patients, families, clinicians, health system managers, administrators, and policy-makers about the availability and benefits of palliative care services.

**Project Safe Conduct**

Project Safe Conduct is a collaborative effort of the Ireland Cancer Center (ICC) and Hospice of the Western Reserve (HWR), both based in Cleveland, Ohio. ICC is a National Cancer Institute designated comprehensive cancer center, and HWR is an independent community-based hospice. Their collaboration exemplifies a model that incorporates these elements into their program design and implementation. The goal of Project Safe Conduct, to create a seamless transition of care for persons with advanced cancer and their families in the ambulatory cancer setting by integrating principles of palliative care, was clearly defined at the onset. The program was initially limited to patients with stage III and IV lung cancer to allow clinician-researchers to test and refine the model with a discrete patient population before considering inclusion of a larger patient group. The project was staunchly supported by administrative and clinical leaders from both institutions, as evidenced by the ICC director’s unprecedented decision to close the cancer clinic to enable clinical staff to attend a day-long retreat to discuss and launch Project Safe Conduct.

The Safe Conduct team, comprised of an advanced practice nurse, a social worker, and a spiritual care provider, represents both acute care and hospice care backgrounds. The team was employed by HWR but physically located within ICC, to reinforce the integration of the palliative care team with the cancer care team. The staffing design reflected the belief that care of cancer patients should be managed and supported by their primary oncologist and that oncologists and their patients can benefit from the support and counsel of trained palliative care professionals. Project leadership implemented extensive cross-training to bridge the differing medical cultures of oncology and palliative care and to provide ongoing support to the teams. Interdisciplinary discussions were regularly scheduled to allow a safe haven for conversation among clinicians about issues of death and dying and the quality of the patient’s and family’s experiences.

Safe Conduct leaders crafted an evaluation plan to collect process and outcome data to assess the impact of the project on the accessibility of palliative care for patients and families; the quality of the care as perceived by patients, families, and clinicians; and resource utilization. Clinician-researchers were able to demonstrate improved pain and symptom management, increased hospice referrals and hospice lengths of stay, diminished hospitalizations, and decreased pharmaceutical costs. These data proved convincing to administrators, who decided to expand Safe Conduct beyond lung cancer patients, extending the service to those with gastrointestinal cancer and other advanced malignancies (see detailed discussion of Project Safe Conduct in Chapter 64).

**Clinical Components of Delivery Models**

Regardless of the diverse clinical settings in which Promoting Excellence projects were created, the clinician-researchers directing these innovative palliative care programs recognized the importance of articulating whom the palliative care program was designed to serve, what the service package entailed, where the services were to be provided, and by whom.

**Identifying Patients Appropriate for Palliative Care**

Promoting Excellence palliative care programs primarily sought to serve seriously ill patients who were of “prehospice” status by current insurance or Medicare criteria but were likely to benefit from the simultaneous provision of disease-modifying treatment and palliative care. At entry into these programs, patients’ prognoses were longer than 6 months and/or their mindsets were oriented toward living as long as possible. Clinicians evaluating the benefits of palliative care for a given patient often considered what is termed the “surprise question”: “Would you be surprised if this patient died within the next year”? Alternatively, they screened for patients’ health service utilization patterns, looking for events such as recurrent hospitalizations and emergency department visits, to identify those who might benefit from typical palliative care services of care management, care coordination, anticipatory guidance, and crisis prevention.

Promoting Excellence projects offer examples of various patient accrual methods, each unique to the goals, parameters, and venues of its particular palliative care program:

- The University of Pennsylvania School of Nursing, in collaboration with Genesis ElderCare, a national nursing home corporation, developed a palliative care assessment tool to identify patients in
participating nursing homes who were appropriate for palliative care.

- The Veterans Administration Greater Los Angeles Health Care System used clinical triggers as eligibility criteria to identify patients with lung cancer, congestive heart failure, or chronic obstructive pulmonary disease, who were appropriate for palliative care.
- The CHOICES program of Sutter Visiting Nurse Association and Hospice in northern California developed non-prognosis-based eligibility criteria focusing on diagnosis, clinical state, and utilization patterns. These criteria were designed to identify patients of higher acuteness who had late-stage chronic illnesses but did not necessarily fit the terminal criteria for hospice enrollment.

**Palliative Care Services**

Comprehensive palliative care programs strive to deliver state-of-the-art clinical care to both patients and their families, with a commitment to respecting the cultural, ethnic, religious, and personal values of those they serve (Table 62–3). The programs emphasize clear communication with patients and families through clinical protocols, education, and quality improvement. Crisis prevention and early crisis management are common components of care planning and practice. Some member of the team who is familiar with the patient and family and knowledgeable about the plan of care is available around the clock. Symptom management for both physical pain and psychosocial distress is conducted in a comprehensive and assertive manner. Symptom management plans are frequently updated to reflect the changing condition of the patient and family. Supportive counseling with patients and families regarding issues of life completion and closure is part of routine anticipatory guidance for these inherently difficult but normal tasks. Families are routinely offered bereavement support after the death of their loved one.

**Palliative Care Personnel**

Comprehensive palliative care programs designed to reach patient populations in challenging settings usually have interdisciplinary teams modeled after the structure of hospice clinical teams. These teams frequently include a physician with expertise in palliative care, a specially trained palliative care advanced practice nurse, a social worker, and a pastoral or spiritual care counselor. Core teams are often enhanced by ancillary team members such as psychologists; pharmacists; pain specialists; physical, occupational, and respiratory therapists; and professionals trained in the therapeutic use of art and music. Together with patients and families, these interdisciplinary teams create multifaceted, individualized plans of care that reflect the patient’s and family’s values and personal preferences.

A near-universal feature of palliative care programs is the presence of one or more “case managers” or “care coordinators.” This position is often recognized by team members as a linchpin for ensuring ongoing monitoring of a patient’s condition and family living situation, assisting with pragmatic issues of access to needed health services, and coordinating consultations and referrals for both life-prolonging and palliative treatments. The care coordinator oversees the implementation of the plan of care developed by the interdisciplinary team, monitors the patient’s and family’s status, and typically leads development of a crisis prevention and management plan.

In non–hospital-based programs, interdisciplinary palliative care teams receive medical direction in a variety of ways, often based on the venue of care, the proximity of the primary provider, and the culture of the local institutional and health community. The goal is to provide appropriate care for each patient and family while preserving, to the extent each desires, the relationships between patients and their physicians. To do so, teams must determine the role that each patient’s primary care physician expects and ascertain each physician’s level of familiarity and comfort with palliative care.

In many practice settings, it is advantageous for the palliative care team to have authority to write orders for diagnostic tests, to adjust medications, and to initiate treatments in accordance with the interdisciplinary plan of care. Some programs reflect a co-management model, wherein the palliative care team assumes primary management in communication and coordination with the patients’ primary care providers. In other programs, the primary care physician continues to write orders and prescribe medications, but the recommendations of the palliative care team are routinely incorporated into the patient’s overall plan of care. An example of this approach is offered by the Comprehensive Care Team at the University of California San Francisco, where the interdisciplinary team, including a palliative care physician, develops palliative care treatment plans that are then formally recommended to the primary care provider for implementation.

Other palliative care programs provide training in palliative care to the medical specialists who serve as patients’ primary

Delivering Palliative Care in Challenging Settings and to Hard-to-Reach Populations

providers. This model has been effective with disease-based palliative care programs, such as the Renal Palliative Care Initiative at Baystate Medical Center in Springfield, Massachusetts, where nephrologists and dialysis unit staff, who had established relationships with the patients, became trained in palliative care.

Palliative care teams can extend their ability to meet patient and family needs by integrally involving volunteers in a variety of supportive capacities, as was evidenced by several Promoting Excellence grantees:

- Staff at Cooper Green Hospital’s Balm of Gilead unit in Birmingham, Alabama, worked with area faith communities to “adopt” a room on the palliative care unit, decorating it and visiting the occupying patients at this public, safety-net hospital.
- Comprehensive Care Team project members, who were faculty at the University of California San Francisco Medical School, created a Community Health elective for pharmacy, social work, and medical students that incorporated visits with terminally ill patients as part of the curriculum.
- Through the Volunteers of America GRACE project, almost 200 prison inmates in four states were trained as “hospice” volunteers to help care for terminally ill fellow prisoners.
- Several Alaska Native communities participating in the Helping Hands project based in Dillingham, Alaska, developed programs in which high school student volunteers lent a helping hand to frail elders and ill members of the community enrolled in the palliative care program.

Table 62-4 provides an overview of the components of models developed by four Promoting Excellence grantees.

---

Educational Components of Palliative Care Models

Education of clinical professionals is a critical component of any strategy to expand access to team-based specialist palliative care programs. The increased awareness achieved through education and training results in increased referrals to palliative care and helps embed attention to comfort and quality of patient and family life within the focus of mainstream practice.

Many Promoting Excellence projects incorporated palliative care topics into required educational in-services, grand rounds and other “on-the-job” training for all disciplines. For example, the project director at Cooper Green Hospital incorporated 15-minute lectures on palliative care topics into daily morning rounds with medical residents. At Baystate Medical Center, nephrologists and dialysis staff incorporated palliative care issues into their regular morbidity and mortality conferences, moving discussions beyond the pathophysiology and metabolic chemistry of renal disease to include questions such as, “Did the patient die well?” and “Were preferences known and followed?”

---

Promising Results

Sound evaluation plans are necessary for innovative palliative care programs to succeed and be sustained within the larger health care system in which they function. Because the Promoting Excellence demonstration projects were designed to build programmatic prototypes of health service delivery, evaluations focused on the feasibility of the programmatic approach; its acceptability among a range of stakeholders, including patients, families, clinicians, and management of the larger health system; and the program’s potential for sustainability. To the extent possible, the palliative care programs also evaluated whether the expanded access to palliative care improved the quality of care as perceived by patients, families, and clinicians, as well as the financial ramifications of concurrently providing palliative care.

Preliminary data on access, quality, and cost from Promoting Excellence projects are exciting and promising. Using various strategies to institute and refine palliative care practices, Promoting Excellence programs experienced improved pain and symptom management and increased advance care planning and coordination, with patients and families reporting enhanced quality of life. Data from these prototypical models suggest that concurrent palliative and cure-oriented care is clinically effective and is associated with systems efficiencies and no increase—in fact, in most cases a decrease—in total expenditure of health care resources.

In the United States, complexities in accounting for health care costs abound. The lack of consistency for pricing and charges and the broad array of independent providers of care contribute to the challenges of assessing actual costs of products and services. Accounting limitations often make it difficult to distinguish between cost reductions and cost shifting to other parts of the health service delivery system, or to patients and their families. With these caveats acknowledged, in looking across the experience of Promoting Excellence programs, it is possible to offer some observations regarding the impact on patterns of resource use that affect costs.

Patients in Promoting Excellence programs often expressed a preference to avoid hospitalization. With good palliative support, their care was typically managed in the home, and crises that might have led to hospitalization were avoided. Expanded access to palliative care teams for consultation and ongoing management was associated with fewer hospital days, fewer unplanned hospitalizations, fewer emergency department visits, and fewer intensive care bed days. The number of hospice referrals and length of service increased; in several programs, days of hospice care doubled or tripled from baseline. More patients spent their last days at home.

Collaboration, creativity, and flexibility in responding to needs of patients and providers are essential for the alignment...
of access to services, quality of care, and costs to be realized. Palliative care leaders benefit from exploring partnerships and engaging in dialogue with insurers and insurance regulators to create more flexible management of coverage benefits. Promoting Excellence projects found that by loosening restrictions on certain insurance benefits and being responsive to patient and family needs, they were able to effectively deliver care with high customer satisfaction while effectively controlling costs.

CASE STUDY
Pathways of Caring

The experience of the Pathways of Caring project at the Department of Veterans Affairs’ (VA) Greater Los Angeles Healthcare System illustrates these results. Although the Pathways project was unique and the number of patients studied was relatively small, the findings exemplify the programmatic experience and trends of other Promoting Excellence projects.

Pathways of Caring clinician-researchers were committed to providing side-by-side disease-modifying treatment and palliative care for advanced life-limiting illnesses, to increase comfort and quality of life for veterans diagnosed with lung cancer, advanced congestive heart failure, or chronic obstructive pulmonary disease. The Pathways model began with the identification of patients within the hospital, clinic rolls, and medical records of the VA Greater Los Angeles health system who had poor prognoses and were likely to benefit from comprehensive symptom management. The project’s goals extended to ensuring relative comfort for patients, coordinating care through the course of illness, and expanding access to home care and hospice. In the Pathways service model, a nurse case manager educates patients and their families regarding decision-making and symptom self-management and provides continuity of care, while serving as the hub of an interdisciplinary team that also includes a social worker, chaplain, dietitian, and physician.

Preliminary data on 54 participants who died while enrolled in the Pathways of Caring program show dramatic differences, compared with a retrospectively matched control group of patients who did not receive the palliative intervention. Available evidence indicates improvements in the proportion of cases with documented goals of care and completed advance directives. Forty-three percent of patients in the Pathways program were able to die at home, compared with 7% of matched control patients. Forty-five percent of Pathways patients died in a hospital or long-term care facility, compared with 68% of controls.

The Pathways program averaged 3.5 hospital days per patient during the final month of life, compared with 8.2 days for the control group. More striking still, the group of patients who died while served by Pathways spent an average of 0.4 days in intensive care during the last month of life, compared with 4.5 days for those in the group not enrolled. Intervention patients averaged far less time on mechanical ventilators in their final month, just 0.1 days per patient, compared with 3.5 days in the comparison group. As shown in Table 62–5, the program’s ability to better manage its patients with life-threatening illnesses in more appropriate and cost-effective settings has important financial ramifications, with overall savings of 45% on the cost of care in the final month of life.

The feasibility of this service delivery model and its acceptance by veterans, their families, and clinicians was clearly evidenced by the appreciation expressed and the steady rise in referrals and caseload. The ability of the Pathways team to document the program’s success, including its salutary impact on the system’s efficiency and use of health resources, provided a convincing argument for sustaining the program beyond the grant’s duration. In fact, the Pathways program has been expanded, with an increased number of case management nurses and palliative care staff physicians, expansion and further integration of the palliative care consultation team, and formalization of an outpatient palliative care clinic.

Discussion

Hospice is acknowledged as a gold standard in the care of patients who are nearing the end of life, yet hospice care is not reliably available to all patients who are dying. A dichotomy between life-prolonging care and hospice care exists in the mindset of clinicians as well as patients. In the United States, this dichotomy has been codified under Medicare, the government program that is the predominant payer of health care for people 65 years of age or older. By statute and regulation, Medicare’s hospice benefit is available only to recipients who are judged to have a life expectancy of 6 months or less and who are willing to forego disease-modifying care. Yet, the distinction between life-prolonging and palliative interventions is arbitrary and without clinical or ethical basis. Indeed, advances in treatments for

*Does not include long-term care facility costs listed separately.

Source: Department of Veterans Affairs, Greater Los Angeles Healthcare System.
late-stage cancer, heart, lung, and neuromuscular diseases continue to blur that distinction. Sometimes treatments primarily intended to prolong life also improve patients’ comfort and quality of life. Conversely, sometimes palliative care provided to address symptoms, alleviate suffering, and support patients and families seems to extend patients’ lives.

The Institute of Medicine’s landmark report, Approaching Death, recognized an urgent need to improve care through the end of life. It called for significant improvements in clinical education, health systems design, and service delivery, as well as changes in health care financing, outcomes measurement, quality improvement, and oversight. In order to meet the growing mandate to deliver patient-centered care, health care systems and clinicians must attend to more than the pathophysiology of disease and the physiology and pharmacology of treatment. Patients with advanced, incurable conditions and their loved ones must be able to expect clear communication and shared decision-making about medical treatments and care plans. They should expect effective management of their symptoms, continuity of care, prevention of or early response to crises, and support for families in their caregiving and in their grief. The early clinical and programmatic results of Promoting Excellence projects have clearly shown that these reasonable expectations are achievable.

The concurrent delivery of palliative care and life-prolonging care is possible and well accepted across a wide variety of settings for health service delivery and to diagnostically and demographically diverse patient populations. This integration supports a higher quality of care, including smoother transitions of care across settings, and results in improved quality of life for seriously ill patients and families. Promoting Excellence projects found that availability of palliative care and enhanced staff training in palliative skills can change the culture of an institution, increasing sensitivity to and ambient skills in management of symptoms and response to the social needs of all patients.

Perhaps the ultimate mark of success of model building in health service delivery is the sustaining or expansion of the projects beyond the duration of grant funding. The large majority of Promoting Excellence projects are continuing. Some have evolved into new programs, and others are being expanded. Collectively, these prototype models of health service delivery proved their feasibility and efficiency within their local health care systems and are highly valued by patients, families and providers alike. They demonstrated that it is possible to align health services to meet the needs of seriously ill patients and their families and, notably, to improve outcomes of care, while remaining fiscally responsible for the financial well-being of health care institutions.

*Conclusion*

The vision of a seamless continuum of care that treats a patient’s disease while also addressing physical, psychosocial, and spiritual comfort and quality of life for each seriously ill person and family is no longer an abstract notion or distant dream. The experience of Promoting Excellence in End-of-Life Care projects provides real-world experience that concurrent palliative and life-prolonging care is feasible and well accepted within a wide variety of settings and patient populations that span various ages, demographics, and diagnoses. The Promoting Excellence in End-of-Life Care web site, http://www.promotingexcellence.org, describes the projects and contains practical clinical, evaluative, educational, and programmatic tools and publications for delivering palliative care in challenging settings and to hard-to-reach populations. (Table 62–6 lists Promoting Excellence publications.) The success of these projects demonstrates what can be achieved and challenges clinicians, managers, and payers of health care to set and keep sights high.

The collective programmatic experience of the Promoting Excellence service delivery prototypes provides the foundation for future change. The next steps are well-designed population-based demonstration projects to advance delivery and study the outcomes of concurrent palliative and life-prolonging care.
care on quality and costs. In this manner, health care systems can evolve to provide excellence in clinical care in an approach that is clinically effective, socially responsible, and culturally affirming.

REFERENCES

Although dying is often assumed to be a medical event, illness, family caregiving, dying, and grief are primarily personal aspects of life. Each of these personal experiences of the individual and family is affected by the communities in which they live.

Communities comprise people who share a stake in life—such as where and under what circumstances they live, work, or worship—and recognize a degree of commonality.

The culture of a community comprises prevalent values, beliefs, assumptions, hopes, and fears, as well as patterns of behavior.

People in Missoula, Montana, offered their town as a laboratory of experience to explore the meaning of living “in community” with one another with regard to advanced illness, caregiving, dying, and grieving.

Research was conducted using various methodologies to obtain data on end-of-life experience and care from a broad spectrum of community members.

By affirming existing values and highlighting discrepancies between what people hope for and what they do or experience, stakeholders from multiple segments of the community engaged in changing professional practice and patterns of social interaction and accelerated cultural change.

**Key Points**

- Palliative care strives to bring the best of clinical practice to the goals of comfort and quality of life for individuals and families living with advanced illness. Toward those ends, it has become a specialty focus within the fields of medicine and nursing.
- Health care is often critically important in the lives of dying people. Yet, dying is fundamentally personal. Life with illness spans the entire spectrum from mundane daily activities, including basic tasks of self-care and family caregiving, to profound existential or spiritual experiences evoked by dying and grief.
- In caring for those whose disease has advanced beyond cure or substantial control, clinicians are wise to remember the subordinate, albeit essential, role that health care plays in lives of people who are ill. In palliative care, primacy and priority are rightfully accorded to people's personal values and goals.
- What matters most to seriously ill or injured people is, almost invariably, other people. Human psychology dictates that the “who” each person experiences himself or herself to be is inextricably connected to others. Injuries and illness strike individuals, but they affect all who love the person stricken. In recognition of these features of human life, a tenant of palliative care is therapeutic focus on each patient with his or her family.

_Homo sapiens_ is a fundamentally social animal, and families and communities have always been integral features of human life. Although families have traditionally been defined by marriage and blood relationships, many contemporary families are nontraditional. A suddenly incapacitated individual who is unmarried or lives alone may initially be thought to have no family yet later be found to have a close family defined by lasting bonds of friendship and love.

Similarly, communities need not be defined only by the borders of cities or towns. Communities exist within neighborhoods, places of work, and worship sites, as well as within...
associations formed by common interests and activities such as schools, social and service clubs, and recreation. These sub-communities form the fabric of human life. Most efforts to improve the quality of end-of-life care have focused on health care settings and health care practices. To improve the quality of life for seriously ill patients and families, understanding and efforts must extend beyond the traditional confines of health care and contribute to building social capital and community responsiveness to the problems of illness, caregiving, death, and grief. It is not surprising that the recently published Hospice Access and Values project identified community not merely as an influence, but also as a core value for end-of-life care.

One Community Offers Itself as a Laboratory of Experience

The Missoula Demonstration Project originated in 1995 when a small group of citizens in Missoula, Montana, who were concerned about the quality of end-of-life experience met to discuss ways for improving care and social support of ill people and their families. Missoula County is situated in the United States western Montana and has a population of approximately 88,000, with approximately 50,000 living within the city of Missoula. Home to a state university, Missoula has a reputation for having a strong sense of community and for being progressive and open-minded in its outlook.

A series of open meetings occurring over a handful of months drew individuals from a variety of backgrounds, including medicine, nursing, pharmacy, social work, funeral and burial services, ministry, aging services, aging advocacy, teaching, and the arts. Participants shared a belief that grassroots social change was necessary to improve quality of life for people with incurable conditions and for their families. Through these open meetings, this group of interested citizens developed a vision for using the geographic community of Missoula, Montana, as a laboratory of experience. Organizers decided to use their town to explore community interventions to improve formal, professional services and informal social support for dying persons and their families that would extend well beyond health care settings.

Under the guidance of a planning committee and founding board of directors, the Missoula Demonstration Project (MDP) was incorporated in 1996. The organization, which is now called Life’s End Institute (LEI), was founded with the mission to study and improve the quality of life’s end. The board of directors believed that research and community-based interventions could play complementary roles in accomplishing lasting change. Research findings have the potential for raising public and private policies, practices, and attitudes that help organizations and individuals. They required, including “support systems provided through workplaces, religious congregations, and other institutions to ease the emotional, financial, and practical burdens experienced by dying patients and their families.” Additionally, the Institute called for “public education programs that aim to improve general awareness, to encourage advance care planning, and to provide specific information at the time of need about resources for physical, emotional, spiritual, and practical caring at the end of life.”

Studying end-of-life experience and care from a community perspective makes sense. Although most medical and nursing professionals encounter patients in health care settings of clinics, hospitals, or nursing homes, the people who become clinicians’ patients live in the context of their families and communities. As the experiences of serious illness, dying, caregiving, grieving, and death inevitably affect each member of a person’s family, each of these experiences is in part communal. All communities respond to members who are living through these difficult experiences in ways that at once reflect and shape community life. Although health care constitutes an essential component of a community’s response, it cannot address the entire range of an individual’s and family’s needs, concerns, and challenges. Therefore, it is important to develop quality improvement programs that include both nonmedical and medical aspects of care in a community-wide context.

The term community often refers to a defined geographic town, city, or county and its residents. In its most general sense, the community can be defined by (1) formal associations of people that are valued by one another and (2) informal social structures and processes (discussions, activities, affiliations, and responsiveness to one another) that reflect commonalities of history, culture, interests, or perspectives that are valued by the participants. Although the noun community conveys stability, by their very nature communities are dynamic, woven by processes and interactions of their members.

Community: A Social Compact with Entwined Self-Interests and Mutual Responsibilities

The primal social compact is founded on offering cooperation and accepting responsibility—self-interest rooted in mutual obligation. The behaviors of people in communities reflect a sense of belonging and recognition of a shared “stake” in life. Although this tendency may be latent and not always obvious, when disaster strikes, such as a flood, fire, or hurricane, the sense of belonging and mutual responsibility becomes readily apparent in the behaviors and interactions of community members who are otherwise strangers. Acute grief has a similar effect of revealing a shared sense of life. In the days following the death of a beloved community figure or a bus accident that claims the lives of young children or the tragedy of a school shooting, people acknowledge a commonality of grief. This impulse toward community occurs spontaneously, but it can also be cultivated.
LEI engaged the population of Missoula in exploring how people might live in community with one another—rather than merely in proximity to one another—with regard to issues of illness, caregiving, dying, death, and grief. Questions were posed in community forums and through focus groups and surveys: What responsibilities do we have to those who are seriously ill or dying—our family members, friends, neighbors, and those we don’t know? What responsibilities do we have as individuals, and collectively as a society? And what, if any, responsibilities do dying people—eventually all of us—have to those we leave behind?

Community Culture: Shared Values, Assumptions, Expectations, and Patterns of Behavior

At the heart of every community is its culture. Culture refers to the set of attributes that collectively characterize a community: commonly held values, attitudes, assumptions, history, expectations, hopes, fears, and customary modes of professional, social, and personal interactions. Dominant cultures, as well as subcultures, can be discerned. Culture encompasses a constellation of attributes that apply both to the community as a whole and to component subcommunities.

Cultural values, attitudes, expectations, and modes of behavior are deeply rooted and instilled individually early in childhood. They are then reinforced in the home, in schools, and in community life. The mutually reinforcing influences of values, attitudes, and expectations create a synergy that gives a local culture its power.

Yet, for all its strength and durability, culture is dynamic. Spontaneous shifts in culture tend to occur slowly. Substantial changes in attitudes and patterns of behavior can span generations; however, spurts of cultural change can occur. At times, national news, such as the death of a well-known civic figure or respected celebrity, brings media and public attention to issues and contributes to a shift in cultural expectations. Contemporary American examples include Richard Nixon’s refusal of further life-prolonging treatment, Jackie Onassis’s choice to be cared for at home as she died, James Michener’s decision to discontinue renal dialysis and allow death to occur, and Nancy and Ronald Reagan’s acceptance of his life with dementia and eventually a natural death at home. Such accounts gave rise to heightened awareness of end-of-life options and, at least transiently, increased requests for living wills and interest in home care services.

Community members’ willingness (or resistance) to address end-of-life issues within formal, professional interactions as well as in informal social settings can strongly influence end-of-life outcomes. People are at once a product of their culture and participants in its ongoing evolution. Cultural attitudes, assumptions, expectations, and patterns of behavior are based in part on the collective previous experiences of its members. These attributes are malleable. Indeed, well-planned, multifaceted interventions can have mutually reinforcing effects on shaping cultural change. Because word of mouth spreads quickly within communities, a significant change in one arena, such as a hospital and nursing home program to routinely assess and treat pain, can give rise to measurable shifts in expectation on the part of patients and their families.

Life’s End Institute’s Research and Continuous Quality Improvement Paradigm

Missoula’s whole-community approach toward improving the quality of end-of-life experience flows from a conceptual framework that supports research and program evaluation and contributes to community dialogue and action. Stewart and coworkers developed a conceptual model that identifies key concepts and domains of clinical end-of-life care and related patient and family health care experiences. Using the structure-process-outcome framework pioneered by Donabedian, the goal of the Stewart model was to integrate quality of life and quality of health care indicators. LEI conducted a series of quantitative and qualitative studies.

This research and quality improvement model encompasses nonclinical as well as clinical aspects of end-of-life experience. It incorporates individual experiences from surveys, interviews, chart reviews, and ethnographic research with aggregate data from regional vital statistics and national Medicare databases. This approach adapts the continuous quality improvement (CQI) model developed in manufacturing and widely used in clinical institutions, expanding the scope and response cycle of the CQI model to fit whole-community applications. The unit of analysis and target of interventions are determined by the specific characteristic, structure, or process that is being measured or affected. For example, geographically bounded areas such as counties, health care institutions, social service agencies, or faith communities each may serve as the unit of analysis. LEI’s framework incorporates two dimensions of evidence that correspond to two types of interventions: individual-focused and community focused.

The community-focused dimension addresses environmental features, collective experiences, and common expectations. Examples of relevant community evidence include (1) a matrix of pertinent resources and services within the geographic community, such as various health care facilities, hospice and home health services, “medicaid” transportation, senior housing, and meals on wheels; (2) a public survey of attitudes and behaviors regarding pain medication and related to advance directives; and (3) focused descriptions of attitudes and behaviors regarding illness, family caregiving, dying, and grief within subcommunities of workplaces, neighborhoods, congregations, and social organizations. Whole-community interventions can affect individual and family experiences in indirect but tangible ways, by creating more supportive milieus.
of community and subcommunity life in regard to illness, dying, caregiving, and grief.

This community-based quality improvement framework emphasizes commonly held values and expectations (including hopes and fears) and assesses the degree of concordance or variance between generally held values or hopes and experienced or observed outcomes. A community’s cultural values are often deeply rooted and difficult to change. Yet preliminary findings indicated that the large majority of Missoula’s population valued aging, dying, comfort and quality of life during illness, emotional and spiritual support of ill and dying people, and family support during caregiving and during grief. LEI’s board of directors, researchers, and advisors recognized that other attributes of culture are more malleable and, if targeted specifically, could lead to a critical mass, or tipping point, and core cultural change. By reinforcing prevailing values, correcting misconceptions, and calling attention to patterns of interaction that are inconsistent with stated values and hoped-for outcomes, it may be possible to change common behavior patterns. Community-based quality improvement efforts operate on—and test—these assumptions.

LEI crafted a platform of research that was carefully designed to examine experiences of illness, caregiving, dying, death, and grief. A set of general questions guided the research plan:

- How do people view death and dying? What is most important to them? What do they hope for—and what do they fear?
- How do people interact with one another concerning end-of-life issues?
- How do people prepare for death, dying, and caregiving?
- How do people die in Missoula? Where do they die?
- What is the quality of end-of-life care?
- How do people care for and support one another—clinically, informally, and socially—during serious illness, dying, and grief?
- How do people perceive care at the end of life?

A variety of methodologies were used to assess pertinent domains of personal and family experience and quality of care. Both objective and subjective data were gathered from mailed individual or family surveys, structured and semistructured interviews, surrogate after-death interviews, and medical chart reviews. Study designs were both prospective and retrospective and gathered either epidemiological or ethnographical information. LEI’s participant-observer study used an anthropological perspective that culminated in a book, *A Few Months to Live.* Knowledge, attitudes, and skills among professionals were assessed by structured interviews, surveys, and standardized tests. Comprehensive community assessment enabled descriptions of patterns of care across institutions or provider groups within a community, levels of quality among available services, and aggregate personal experiences of community members (Figure 63–2).

**Key Findings**

Findings from the series of baseline research studies conducted during 1997–2000 informed and focused LEI’s community engagement and quality improvement interventions. These studies were funded by a variety of private foundations, including the Nathan Cummings Foundation, the Robert Wood Johnson Foundation, the Arthur Vining Davis Foundations, the Kornfeld Foundation, and the Mayday Fund.

Although a detailed report of the study results is beyond the scope of this chapter, key findings that helped shape Missoula’s community-based interventions are presented.
agreed that “It is important to take the lowest amount of med-
icanes should only be taken when pain is severe;” 42
over time. “Similarly, "Most people taking pain medicines will become addicted
Thirty-two percent agreed with the incorrect statement that
beliefs that would complicate effective pain management.

Figure 63–2. Variety and breadth of community-based research.

Values
Study data revealed overall broad agreement among the gen-
al adult population of Missoula and subcommunities of
professionals with respect to values and expectations of end-
of-life experience and care, albeit with some differences in fre-
quency and intensity of attributes. For instance, there was
general accord in response to the statement, “Dying is an
important stage of life,” in a series of surveys. Seventy-five per-
cent of respondents from a sample of 596 members of the gen-
eral public endorsed the statement. In a separate survey of 41
faith community leaders, 98% strongly agreed.26 A subsequent
survey of practicing attorneys found that 87% of those most
experienced with advance directives and 83% of those less
experienced concurred with this statement.27

Misconceptions
Misconceptions can impede the best efforts to improve peo-
ple’s comfort and quality of life. Fully 50% of respondents
among the general public expressed some to extreme worry
about dying painfully, yet significant proportions harbored
beliefs that would complicate effective pain management.
Thirty-two percent agreed with the incorrect statement that
“Most people taking pain medicines will become addicted
over time.” Similarly, 36% erroneously thought that “Pain
medicines should only be taken when pain is severe”; 42%
gave that “It is important to take the lowest amount of med-
cine possible to save larger doses for later when the pain is
worse”; and 42% agreed that “People are often given too much
pain medicine.”

Gap Between Expectations and Outcomes
“Being able to stay in your home” was rated as important in
helping to deal with one’s own dying by 85% of respondents in
a survey of the general public. However, in-depth chart
reviews of 207 people who died “nonsudden” deaths revealed

that only 22% were in a private residence during the last
moments of life, and only 18% received hospice services.

“Freedom from pain” was important to 92% of community
respondents, yet medical chart reviews of 207 decedents indi-
cated that 78% experienced pain during the last week or month
of their life. Eighty-eight percent of community respondents
prospectively indicated that “spiritual well-being” was impor-
tant during the dying process, but in a separate, retrospective
study, 21% of bereaved loved ones rated the help they received
from their church as the worst it could possibly be. Indeed,
only 34% of faith community members in a multicongrega-
tional study said their church does a good job of providing
support for families during illness. And even fewer congre-
gants (29%) indicated that their church does a good job prov-
iding support for families at the time of death.

Although “not being a burden” to loved ones was rated as
important in the dying process by 88% of general community
respondents, respondents often did not engage in activities
that prepare those who are likely to make decisions for them.
For instance, 72% of this general public sample did not have
advance directives, which allow individuals to express their
own health care preferences, designate someone to speak for
them, and are widely acknowledged as a way to reduce the
emotional burden on families at times of medical crises. Fur-
ther, 41% of this general public sample said they were unlikely
to speak freely to their loved ones about death and dying. Hos-
pice services can also reduce the family burden in caring for a
dying loved one, yet 39% of surveyed local residents had never
heard of hospice or had heard only a little about it.

Insufficient Preparation Among Professionals
Professionals from clinical disciplines as well as education,
ministry, and law acknowledged that they have an important
role to play in serving clients who are dealing with illness,
death, or grief, either themselves or in their families. In each
discipline, significant proportions of respondents reported
less than adequate training and professional preparation to do
so. Among attorneys, 36% had little or no training in advance
care planning. Among member of the clergy, 34% had no
training in issues related to illness and death, and 66% said
that what training they did have had not prepared them well
for ministry related to illness. Seventy-six percent of school
teachers were either unaware of end-of-life curricula or not
familiar enough to use them, and 44% were unprepared to ini-
tiate a conversation with a student about the student’s serious,
potentially life-threatening illness.

Even with suboptimal formal training, personal experience
with advance care planning would improve professionals’ abil-
ity and comfort in assisting others. However, in proportions
similar to those of the general public, local professionals did
not prepare for their own end-of-life experiences and care.
Only 27% of physicians, 29% of attorneys, and 30% of clergy
reported having named a power of attorney for health care to
convey their wishes and help ensure that their preferences
were followed.
In summarizing key findings to the Missoula community, LEI reported the following conclusions:

- We don’t adequately prepare for end-of-life experience and care.
- Many of us have misconceptions that can adversely affect our care and increase the variance between what we hope for and what occurs.
- What we value and hope for is not always what we get.
- How we act is often inconsistent with what we value, desire, and hope to provide or receive.

Community Engagement and Quality Improvement

LEI’s quality improvement strategy reinforced widely-held affirmative values and focused on identified gaps between what people value and hope for and actual outcomes—what people receive or experience. Where a gap existed between expectations and outcomes and patterns of behaviors were inconsistent with existing values and aspirations, LEI attempted to bring these patterns of professional and informal social interaction into alignment with widely held values and desired outcomes. Similarly, research data were used to identify prevalent expectations that might be raised in ways that improve the quality of care and end-of-life experiences in the community.

In summary, LEI focused on three specific targets for quality improvement: (1) formal services and care that are documented to be at variance from recognized standards for professional practice; (2) prevalent misconceptions by the general public and professionals that potentially contribute to adverse outcomes, inconsistent with widely-held values and hopes; and (3) common patterns of professional practice and informal social interaction that are incongruent with prevailing values and hopes and consequently contribute to undesirable outcomes.

Recognizing that community-wide quality improvement would not be achieved by single program or by a “top-down” approach alone, LEI chose a strategy of community engagement. Research and feedback proved essential to this approach. In addition to general public surveys and outcomes research, pertinent subcommunities provided information from their own experiences and professional practices. Once collected and analyzed, these findings were reported back. When professional groups, whether clinicians, teachers, clergy, or attorneys, reviewed their data and observed the discrepancies between what they value and hope to provide in their service and what occurs, the result was an immediate and deepened sense of ownership of the issues and expressed resolve to improve practice patterns and outcomes. Professional groups responded with education efforts and quality improvement activities by and for their members. As a center for expertise in end-of-life content, on request, LEI remained available to offer assistance to groups within Missoula, as well as to consult with other communities across the nation.

Quality Improvement Initiatives and Programs

From 1999 to 2004, a wide array of quality improvement initiatives and programs emerged from this approach to community engagement. Examples of initiatives organized by sub-communities and topic foci are presented here, with recognition that activities are rarely discrete and that overlap and synergy of efforts are desirable.

Health Care Community

A 23-member Advance Care Planning Task Force with representation from most clinical settings as well as attorneys, chaplains, disability advocates, social workers, faith community leaders, and retirees developed My Choices, an advance directive form that combines a power of attorney for health care and a living will. The consistent availability of this form has bred familiarity among health care providers, who are able to more quickly locate and understand the information it contains. A companion booklet was developed to provide information about exploring and expressing one’s health care preferences in situations of life-threatening illness and injury.

To further improve the accessibility of advance directives, nine Missoula organizations collaborated to develop the Choices Bank, which stores scanned advance directives on a secure Internet site (http://www.ChoicesBank.org) and makes them available to authorized individuals 24 hours per day. The Choices Bank uses relatively simple and inexpensive technology, which facilitates its replication by other communities. Choices Bank evaluations to date reveal a dramatic increase in depositors’ confidence that their advance directives will be found when they are needed. Not only are 82% of depositors “extremely satisfied” with the Choices Bank, but almost 80% reported that they had recommended the Choices Bank to their families and friends. What is more, 94% of depositors had discussed the health care choices they made with their families, 65% with their doctors, and 59% with close friends.

To assist patients and their doctors and nurses in assessing physical discomfort, a community-based Pain Task Force printed pain rating scales in bookmark formats. More than 4400 pain scales have been distributed throughout Missoula.

Pain is now monitored as a vital sign in the two hospitals, one home health agency, and a local hospice program. Across acute and long-term care facilities and hospice and home care programs, pain management is now a routine focus for continuous quality improvement. Three of the largest local health care institutions have begun to regularly monitor performance with pain assessment and management and have developed interdisciplinary teams to evaluate and monitor pain management. The teams monitor the quality of the pain management process, including staff competency, effectiveness of treatment, and outcomes such as satisfaction, cost, readmissions, and length of stay. Both local hospitals were awarded...
commendations for their pain management programs by the Joint Commission on Accreditation of Health Care Organizations.

To improve spiritual care at the end of life, 12 health care institutions assessed their current services and implemented quality improvement interventions. A home health agency developed a Spiritual Care training module for all nursing staff. One hospital adapted a referral card, a tool staff members can use to know when to call a spiritual advisor (see Table 63–1).

**Faith Community**

Fifteen local faith communities assessed their capacity to provide spiritual care at the end of life, reviewed their results, and implemented quality improvement interventions. One church formed a Health Cabinet that works with their parish nurse and includes a focus on end of life; another collated bereavement materials as a first step in addressing grief issues in their congregation; and a third started an education series on end-of-life issues. A home-based volunteer program, Caring Friends, was developed by one faith community to assist family caregivers within their congregation.

A nondenominational Caring Circles program was developed with support by parish nurses and community volunteers. Caring Circles helps family caregivers by recruiting and training teams drawn from individuals within a caregiver’s network of family, friends, neighbors, coworkers, or congregants who are then prepared and coordinated in providing assistance with routine tasks such as shopping, cleaning, mowing, and cooking, as well as transportation for appointments or errands. The program informs families and Caring Circle volunteers about available resources such as hospice, topical health issue information, advance care planning, and other avenues for reducing the burden of family caregiving. The program is partially self-supported by volunteers who make and sell “Wearing Caring” jewelry. An added advantage to this strategy is that the distinctive jewelry itself provides an opportunity for the wearer to explain and promote the Caring Circle program.

**Legal Community**

The Wise Counsel project developed as a collaborative effort between LEI and representatives of the State Bar of Montana, the University of Montana School of Law, and the Montana Association of Legal Assistants. A national advisory panel of accomplished legal, medical, and ethics experts helped shape the research design. All four District Court judges in Missoula County signed a letter encouraging recipients to complete the Wise Counsel survey. Seventy-one percent of attorneys did so, an impressive response rate. After reviewing survey results, a statewide elder law continuing legal education seminar with the State Bar of Montana was developed, and law professors at the University of Montana included end-of-life curricula in their elder law classes.

**Table 63–1**

<table>
<thead>
<tr>
<th><strong>Spiritual Care Referral Card</strong>*</th>
</tr>
</thead>
</table>

| **Spiritual Assessment** |
| Listen for verbal clues: |
| • Patient refers to God or higher power |
| • Patient talks about church, prayer, worship, or a religious or spiritual leader |
| • Patient makes comments such as “It’s in God’s hands now,” or “Why is God letting this happen?” |

| Look for visual clues: |
| • Religious or spiritual books: Bible, Torah, Koran, etc. |
| • Symbols in room: cross, star of David, etc. |
| • Articles: prayer beads, medallions, crosses, pins, etc. |

Assess for religious concerns such as diet, special observations, or refusal of blood.

Listen carefully to your patients’ life stories: who they are, who they have been, for this is the key to understanding their unique spirituality.

| **Spiritual Diagnosis** |
| These are some cues that a patient may be experiencing spiritual distress or despair: |
| • Anticipatory grief |
| • Unable to participate in normal religious services |
| • Severe depression, suicidal ideation |
| • Concern about their relationship with God |
| • Feeling abandoned by God, unable to pray |
| • Anger toward God or established religion |
| • Loss of hope or spiritual beliefs |

If you assess spiritual distress or despair, please contact the Chaplain right away.

| **Interventions** |
| • Joining with the patient in prayer or scripture reading if you are comfortable doing so. |
| • Being with the patient in respectful silence can be comforting. |
| • Referral to the patient’s own religious leader and/or hospital chaplain. |

School-age Education Community

Schools are a microcosm of the existing community, yet there was no system in place to support students with issues of death and bereavement. The Schools Task Force, consisting of local teachers, administrators, librarians, secretaries, counselors, parents (including those who home-schooled), and students, developed an age-appropriate bibliography of books on grief for local teachers and a literature kit and resource list for teachers and parents that featured extended activities on bereavement and coping after the death of a grandparent or other significant loss. The task force continues to collaborate with the American Hospice Foundation to conduct its annual Grief at School Workshops.

Arts Community

Community engagement employing the arts moves beyond merely placing artwork in hospitals and other clinical settings. The arts can play an active role in stimulating introspection, discussion, and community-based efforts.

In Missoula, visual and performing arts have proved to be powerful means for arousing emotions, raising awareness, and stimulating conversation, especially among those who may not otherwise seek conversation about the end of life. A variety of art forms, from paintings and photography to poetry, literature, live theater, and music, have engaged the public in exploring illness, caregiving, death, and grief. Programs have involved cultural organizations, such as museums, symphonies, and drama groups, as well as community organizations of schools, churches, and the local Area Agency on Aging.

The staged reading of a play, Vesta, by Bryan Harnetiaux, about an elderly woman’s struggle with progressive frailty, loss of independence, and extended family dynamics, was presented to a full high school auditorium. Students invited their grandparents to attend and participated in a discussion session after the performance. A reception and exhibit of evocative self-portraits by a well-known Canadian artist, Robert Pope, created while the painter was living with progressive cancer, was hosted at the Missoula Art Museum and drew record numbers of attendees. Since then, the art museum has exhibited various works on themes of illness, dying, and grief.

In conjunction with the local University repertory theater group, LEI produced the Pulitzer Prize–winning play, Wit, to high attendance for five successive nights. After each performance a “talk-back session” was moderated by one or more local professionals, including chaplains, social workers, doctors, nurses, and ministers.

Participatory and experiential art activities have taken a number of forms. To assist individuals and families in honoring a deceased loved one, local artists have conducted Images and Objects of Remembrance workshops. Participants are instructed to bring photographs and small symbolic objects to transform into memorials that recall and celebrate the person who has died. Those who wish can have their image or object of remembrance displayed in a local cafe or gallery. These workshops have typically preceded Missoula’s annual Festival of the Dead celebration, a week-long calendar of activities culminating in an evening, downtown parade on All Saints Day.

A collaborative project with KUFM, a public radio station, produced 32 radio programs or segments with end-of-life themes that were broadcast over 5 days. The content was varied and was tailored to a diversity of audiences listening at times throughout the broadcast day. These programs reached a potential audience of 300,000.

General Community

In recognition of the value that life review and storytelling in the experiences of seriously ill individuals and their friends and families, a group of community members joined together under the auspices of LEI as the Life Stories Task Force. They created a storytelling newspaper insert, “Everyone Has a Story, Share Yours!” which was a collection of end-of-life narratives, many both poignant and humorous, and emphasized the value of storytelling, especially as the end of life approaches. This tabloid was distributed to 20,000 households via the local daily newspaper.

The Life Stories Task Force also designed a project to elicit and help individuals record their stories with the intention of contributing a meaningful experience and enhancing the quality of life for dying persons. A short set of guidelines and suggestions were developed into a booklet, Gathering Life Stories of the Dying (available at http://www.lifes-end.org/gathering_life_stories.phtml). A collection of life stories is available in the public library. This task force proved so successful that members chose to develop a separate nonprofit, community-based organization called StoryKeepers, Inc. (http://www.mystorykeepers.org/mystorykeepers/). This new organization holds two workshops a year to improve skills in writing life stories and sponsors an annual storytelling festival.

LEI seeks to involve many segments of the community and people from all walks of life—because all are stakeholders. Although it is premature to assert that the community of Missoula has been transformed, it is safe to say that the 5 years of intense activity have heightened awareness of living with illness, family caregiving, dying, and grieving. These subjects are no longer relegated to the periphery of awareness or actively avoided. Instead, they have become matters for discussion in professional groups, as well as organized social and informal discussions, and are recognized as important aspects of community life. For example, the local newspaper regularly prints editorials pertaining to end-of-life issues, the art museum continues to display exhibits that address chronic illness and loss, and philanthropic organizations as well as small businesses regularly request LEI staff to speak to their members about advance care planning and caregiving. Topics pertaining to life’s end are no longer uncommon in public discourse.
Although organizations often resist change, because people’s values were affirmed and achievable goals were highlighted, individuals from many walks of life and various segments of the community recognized their own and their organization’s self-interest in quality improvement. Thus, resistance to LEI’s efforts has been minimal.

The history of LEI is still being written. As with most community-based, nonprofit organizations, funding remains a constant challenge and the future is never secure. But whether or not LEI remains active, the process of cultural maturation concerning end-of-life issues cannot be reversed. Interest is high, and professional and cultural activities to advance people’s values and meet their expectations will continue. This “genie” has been released and will not be forced back into the bottle.

Conclusion

Citizen and consumer efforts to improve end-of-life experience are necessary complements to initiatives in health care and can enhance general social support as well as the quality of practice among professionals in law, ministry, and education. An understanding of strategic approaches that are rooted in community and culture expands the realm of effective advocacy and activism.

Community-based research and social change efforts have been successful in other areas of life. Public health interventions and campaigns have focused on a variety of social problems, including unmet needs of the chronically ill, primary prevention of cardiovascular diseases, reduction of tobacco use, preventing low birth weight, eliminating child abuse, and diminishing drunk driving, to name a few.

Act Clinically, Think Culturally

Affirmative cultural values regarding end-of-life experience and care are prevalent and augment community-based efforts to improve the quality of life’s end. Unfortunately, also common are misconceptions and low expectations regarding illness, caregiving, dying, and grief. People anticipate suffering and hope that it can be avoided or suppressed. Rarely are periods of age-related decline or the experience of dying anticipated as potentially valuable times of life.

Palliative care clinicians empirically know that these inherently difficult times are also inescapably important and can become profoundly meaningful events in the histories of patients and their families. Under conditions of comprehensive care, effective symptom management and sufficient social and family support, people have the opportunity to review their lives together and their relationships, and they have a chance to say and do the things that matter most to them. The social stature of nurses and physicians and their expertise in matters of illness and dying provide them with invaluable opportunities for cultural leadership.

Although a national crisis surrounds the ways people are cared for and the ways they die, aging and dying happen to one person and one family at a time. Palliative care providers can act clinically and culturally. In taking the best care possible of each patient and family, clinicians can contribute to the health of their communities. In so doing, they can contribute to a maturation of the culture and affirm a social covenant to care for one another through the very end of life.

The details of developing and implementing an integrative model of palliative care are discussed in this chapter. The concepts that contributed to the success of this program were having a well-defined vision; obtaining support from top leadership; developing an extremely detailed step-by-step plan; creating an education plan; role modeling how to deliver “bad news”; creating an environment conducive to family conferences for decision-making; and establishing outcome measures for evaluation.

Project Safe Conduct, an integrative model of delivering palliative care, was a collaborative partnership between Hospice of the Western Reserve (HWR), an independent large community-based hospice, and the Ireland Cancer Center (ICC) at Case Western Reserve University and University Hospitals of Cleveland, a National Cancer Institute (NCI)-designated cancer center. The project name, Safe Conduct, is taken from concepts in Avery Weisman’s *Coping with Cancer*. He coined the term *safe conduct* as “the dimension of care that guides a patient through a maze of uncertain, perplexing, and distressing events.”

In 1997, *Promoting Excellence in End-of-Life Care*, a national program office of The Robert Wood Johnson Foundation, put out a Request for Proposals. The ICC, in collaboration with HWR, submitted a letter of intent. Of the 678 letters of intent, 59 submitters were invited to write a full grant proposal; 24 had a site visit; and 4 of the 22 who received grants were cancer centers.

Normally, a formal needs assessment would be performed, but the grantees at ICC were already aware that end-of-life issues were not being addressed as much in depth as they wanted. Additionally, they realized the need for input and expertise from their colleagues at hospice. The HWR staff were extremely interested in increasing access and decreasing barriers to palliative care for those patients receiving aggressive therapy.

---

*Key Points*

- “Safe Conduct” guides patients and their families through the cancer disease trajectory.
- The safe conduct team provides “safety” through times of uncertainty, confusion, and fear for patients and their families.
- An interdisciplinary team with expertise in end-of-life care is integrated with the acute care model, and this becomes the standard of care.
- The philosophies behind acute care and end-of-life care blend.

---

You cannot treat a person like a textbook and expect them to live. You have to treat them like a whole person and that is what the Safe Conduct Team does. They treat the whole person.

—Daughter of a Safe Conduct patient
Vision

Throughout this chapter, the elements for success that were identified in Project Safe Conduct are discussed. The first of these was a well-defined vision that aligned the program with the missions of the individual institutions. Philosophically, both ICC and HWR agreed that cancer patients should have an opportunity for life-prolonging treatment and for aggressive care in terms of palliative care (i.e., managing pain and symptoms and addressing psychosocial, spiritual, and life closure issues). These two goals are not mutually exclusive. In fact, the Project Safe Conduct designers viewed it as their obligation to patients to acknowledge and address both. To accomplish this, an environment conducive to open communication had to be created so that staff members could simultaneously talk about both life-prolonging treatment and life closure, when appropriate, and provide aggressive pain and symptom management. This resulted in the creation of more options regarding end-of-life care. Those individual patients who chose to continue with aggressive chemotherapy until they died were also supported with palliative care via the SCT.

Goals of This Model

The overall goal was to create a seamless transition from curative to palliative or end-of-life care for persons dying of cancer and their families in the ambulatory cancer setting by integrating the principles of palliative care. To accomplish this purpose, the following four aims were identified:

- Implement pain and symptom management care paths.
- Educate providers about the same.
- Improve patient/provider communication concerning end-of-life decisions.
- Increase community awareness regarding end-of-life issues.

Two guiding principles were identified that philosophically support the rationale for developing an integrative model of palliative care. Both HWR and ICC believe that cancer patients should not be separated from their primary oncologist (and staff) at the end of their lives, because these relationships are well established, are grounded in trust, and are important psychologically to both parties. Second, the hospice model of care embraces a holistic and family-centered approach focused on enhancing the physical, emotional, social, and spiritual qualities of life. The goal was to implement this holistic approach for patients with cancer regardless of treatment, curative intent, or timeline for survival. As treatment fails, patients and families need increased support from their oncologists, who have provided their care for years. To have the capacity to do this well, oncologists need the support and counsel of trained end-of-life caregivers, in this case the SCT.

The unique innovative aspects of this model of palliative end-of-life care were twofold. First, the SCT was integrated into the standard care of the patient, whereas in other models the patient is separated from the primary oncologist and introduced to a separate team for palliative care. This model realigns the delivery of good cancer care to incorporate the simultaneous provision of palliative care. Second, the creation of a team with expertise in end-of-life care that functions in the acute cancer setting represents a combining of two entirely different philosophies of care—acute cancer and end-of-life—that is both unique and innovative.

Development of the Framework

The second element of success was an extremely detailed, step-by-step plan. In the most skeleton explanation, the SCT—composed of a nurse, social worker, and spiritual care counselor with expertise in palliative/end-of-life care—would integrate into the greater team at the ICC. This team would track the patient with the primary oncologist and integrate palliative care principles with a resulting synergistic outcome. From HWR's perspective and expertise in end-of-life care, five essential elements should be considered.

- The team would be composed of a nurse, social worker, and spiritual care counselor.
- The team would function as an interdisciplinary, not a multidisciplinary, team.
- The team would be housed at the ICC.
- All members of the team would share the same physical space.
- The unit of care would be patient and family (whomever the patient identified as family).

Initially, there was agreement on all areas except the composition of the team. The ICC researchers immediately agreed with the nurse and social worker, but questioned why a spiritual care counselor was necessary. The inclusion of this team member is extremely significant, because spiritual care is a major part of end-of-life care and is one area that distinguishes palliative care from care delivered in most acute care settings.

Collecting Baseline Data

Before beginning the project, the SCT devoted 4 months to collecting baseline data, creating care paths and documentation forms, and educating themselves as well as those other individuals who would come in contact with any aspect of the project. The study population selected was patients with stage IIIb or IV lung cancer, because the overall prognosis for these patients is poor and part of the overall goal was to determine whether hospice referral rates among appropriate patients could be improved.
Creating a Pain Care Path

The second major task for the SCT was to create a Pain Care Path, because one of goals of the ICC was to improve pain management for patients in the ambulatory cancer center. A retrospective chart review of 149 lung cancer patients who died in 1997 revealed limited documentation of pain assessment and management. In those situations in which there was documentation, no standardized protocol was followed.

The Pain Care Path is a decision tree for pain management. This standard of care also includes guidelines and supplementary forms with specific directions for implementation. The guidelines identified in the legend of the care path include pain assessment; opioid reference table; adjuvant analgesics; management of side effects; nonpharmacological interventions for psychosocial, spiritual, and physical pain; and patient/family pain education.

Of equal importance was the creation of a Pain Flow Sheet, which was designed to monitor the patient’s pain management over time and to document actual practice. These two tools work well together: the Pain Care Path is “how you do it” and the Pain Flow Sheet is “how you document what you are doing.” Both tools, which are extremely detailed and user friendly, can be downloaded from http://www2.edc.org/lastacts/archives/archives/july02/painflow.pdf and http://www2.edc.org/lastacts/archives/archives/july02/paincare.pdf (both accessed April 25, 2005).

The SCT and the pain consultant to the team led a mandatory meeting for all ICC nursing staff in which the principles of pain management, the Pain Care Path, and the Pain Flow Sheet were reviewed. As part of the education on pain, all ICC physicians and nurses received A Cancer Pain Management Guide, created by the SCT. As a result of this education, all patients at the ICC now have a Pain Flow Sheet placed in the front of their charts. When the chart is opened, the first thing in view is the Pain Flow Sheet. This serves as an objective way to determine whether patients are being assessed at every visit for pain.

Another aspect of pain management to be assessed and evaluated was the prescriptive patterns of physicians. Successful pain control was achieved using the World Health Organization’s Analgesic Ladder Model and Agency for Health Care Policy and Research Pain Guidelines. Consultations with the pain specialist declined as ICC and SCT staff became increasingly skilled in implementing the Pain Care Path and protocol. Addition of a master’s level nurse practitioner to the SCT further enhanced the team’s ability to manage pain. Also, the Medical Director of HWR was actively involved at the weekly interdisciplinary team conferences and was instrumental in enhancing pain and symptom management with interventions such as the use of methadone for pain, specifically neuropathic pain.

At the time the SCT started working closely with the oncologists, some were immediately prescribing fentanyl patches; others routinely prescribed expensive opioids, and none used methadone. The advanced practice nurse became a major role model for the oncologists and over time gained the confidence of colleagues by her skillful and reliable interventions. The outcome was a change for the positive in prescriptive patterns.

Implementing the Education Plan

As part of the overall development plan, an extensive cross-training program was systematically created to bridge the differing cultures of aggressive cancer care and palliative care. There were many layers of professionals to be educated in end-of-life care, oncology, and Project Safe Conduct. The first was the SCT, whose members did not have a background in oncology, resulting in a knowledge deficit. Formal classes were provided to increase their general knowledge base about the lung cancer population and clinical trials. Time was spent shadowing staff in both radiation therapy and chemotherapy. An additional member of the project was the research nurse, who obtained informed consent from patients and administered the measurement tools. Her background was in oncology nursing, with limited knowledge of end-of-life care. An observational experience was done at the residential facility of HWR, where the nurse shadowed all disciplines to gain a better appreciation of the interdisciplinary team model and the blending of roles, as well as increased knowledge in palliative/end-of-life care.

A formalized education plan was implemented so that all staff members who might come in contact or work with the SCT would be oriented to the demonstration project before starting. Written information explaining the purpose of the project, identifying all core SCT members (by name, telephone and pager numbers, and how to contact them), and detailing the process of patient enrollment in the study accompanied the presentation given by the SCT members.

Members of the SCT participated in patient visits and spent one-on-one time with the medical and radiation oncologists. This provided the opportunity for SCT members to dialogue with the physicians and establish their individual preferences. Also, this time provided an opportunity to increase their knowledge base and to begin establishing rapport with the oncologists, staff, patients, and families.

Unwavering Support from Clinical and Administrative Leaders

The third and foremost reason for success was the endorsement and staunch support from the leadership of both HWR and ICC. As a kickoff to Project Safe Conduct, a day-long retreat was scheduled to discuss and launch the project and invite the oncologists to participate in the study. A psychologist from California who was knowledgeable about hospice and end-of-life care facilitated the retreat and provided support for the oncologists through some team-building activities. The unprecedented decision of the ICC Medical Director to schedule no patient appointments on the day of the retreat, so that key staff
members and the oncologists could attend, was a powerful unspoken signal of the significance of this project.

From HWR, the Chief Executive Officer provided leadership support through his knowledge of palliative/end-of-life care, financial support from two large local grants for the salaries of the SCT, and in-kind support of half of the salary of the project director.

At the operational level, the Vice President of Clinical Services at ICC and the Project Director from HWR had weekly planned meetings to plan strategies for the daily implementation of the project. The Project Director oversaw every detail of the project and also developed and supervised the SCT; however, she was an outsider to the ICC system. Her counterpart at the ICC was extremely knowledgeable about the internal management system and helped the Project Director navigate through the system. This relationship was a key to success, because a marriage of two entirely different philosophies took place, and an outsider to a system was responsible for the operation of the project.

Cultural Change

Before the project was initiated, outsiders from hospice looking in at the cancer center made assumptions that “the physicians must not be talking with patients about end-of-life care and hospice.” As the two systems worked beside one another, the understanding of HWR personnel changed dramatically. There were excellent oncologists at ICC who did have those conversations about end-of-life options. However, there are always patients who, despite the circumstances, respond with, “Yes, but I want to continue with chemotherapy regardless of the outcome.” Certainly that is the individual patient’s choice. All patients were given the option of whether to go into another clinical trial or transition into end-of-life care when the disease was not controlled. This close working relationship with the oncologists changed the hospice workers’ impressions of what occurs on a daily basis at the cancer center.

Implementation Strategies

Project Safe Conduct was created as a demonstration project under The Robert Wood Johnson Foundation grant and as a research effort on the part of the ICC. Only lung cancer patients with stage IIIIB or stage IV disease were eligible to enter the study. A total of 233 patients were enrolled in the study over 2 years (1999–2001). Fifty-one percent of the patients were female, and 39 percent were African American, which is representative of the demographics of Cleveland in terms of gender and race. The average length of stay with the SCT was 116 days, and at any given time there was a caseload of approximately 80 patients.

At the initial visit with the medical oncologist, the physician discussed the option of joining the clinical trial, explaining that the interventional SCT would work closely with the physician in the ongoing care and management of the patient’s physical, emotional, social, and spiritual needs. If the patient agreed, during that same visit the nurse researcher obtained informed consent from the patient and administered three instruments—the FACT-L and the Missoula VITAS Quality of Life Index, both of which measure quality of life, and the Wisconsin Brief Pain Index. At the second visit, the SCT was introduced as a team so that the patient and family would become familiar with the team members. During that visit, the patient and family were introduced to the idea that family conferences would take place periodically. Also the team always asked, “How can we be of most help to you, right now, today?” Experience demonstrated that frequently there was a concern, symptom, or problem that could be addressed very quickly, immediately increasing the comfort level of the patient and family.

At every visit for chemotherapy or radiation therapy, office visit, or diagnostic test, some or all members of the SCT met with the patient and/or family, because this model focuses on the patient and family as the unit of care. Depending on the concerns of that day or week, the support and interaction of the SCT with the patient and family were very fluid and flexible. At some visits the total time was spent with the patient, whereas at others, might be with the family, because not everyone was on the same page or even the same chapter in the book at the same time. All members of the team at some point contacted those patients receiving chemotherapy over several hours during the visit.

Any time that pain medications were titrated or symptoms were treated, the advanced practice nurse called the patient at home the next day to determine the effectiveness of the intervention. All members of the team frequently interacted with patients and family members between on-site visits by telephone or e-mail.

Family Conferences: Delivering “Bad News”

One of the goals of the project was to improve communication through planned family conferences. Anyone on the larger team, including family members, could request a family conference. Sometimes the SCT held these conferences in the patients’ homes, because frequently this resulted in an entirely different perspective. Family conferences were automatically scheduled at the completion of a clinical trial, because that is always a decision-making point. Typically, a computed tomography (CT) scan is scheduled to evaluate whether the cancer has responded to the therapy. The Project Director established a process that was set in motion at that time. The SCT was responsible to know the results of the CT scan and to discuss the options for treatment with the oncologist. Patients were informed that this would be a decision-making time and were encouraged to have members of their family present.

As with any topic, the level of confidence of the oncologists in delivering bad news varied greatly. Before holding the conference at which bad news would be given, the SCT usually
had a meeting with the oncologist to discuss what the options were and to share with the oncologist from their perspective how prepared the patient and family were for the information. As a result of the intense work of the SCT, it was not uncommon for patients to be prepared for the news when treatment was no longer effective and the option of hospice-level care was presented. The team members were experienced in how to prepare and guide patients and families. Over time, the Project Director observed the following stages of learning and comfort displayed by the various oncologists when delivering bad news: call a member of the SCT to assist; don’t leave me, keep me company; SCT take it from here; and finally, a seamless transition with the oncologist and SCT discussing the bad news with the patient and family.²

One of the ways senior faculty learned how to deliver bad news was by observing the SCT initiate the conversation to shift goals from cure-oriented to comfort-oriented care. The role-modeling and mentoring of senior faculty on the process of how to effectively deliver bad news and bridge the differences between palliative care and acute care was another element of success.

Team Conference

Weekly, a team conference using a hospice model took place. The Project Director, who was an advanced practice nurse with years of hospice experience, facilitated the conferences. Others in attendance were the research nurse, the SCT, the hospice physician, and the medical psychologist, who acted in a consultative role. The oncologists did not attend the weekly team conferences, although they were welcome. Their attendance was not logistically possible, because the SCT worked with more than eight oncologists and fellows who had entirely different schedules. Because the SCT was in the same building, team members could personally talk to the oncologists, e-mail them, page them, or call them by telephone.

The format for the team conference was to review any deaths that had occurred during the past week, any new admissions, and part of the active caseload and revise the plans of care with the input from all members of the team. The facilitator role-modeled how interdisciplinary teams interact and work effectively—something that takes many months to develop. New team members had to learn the roles of all other team members and how to blend their roles and still respect boundaries. Also just-in-time learning frequently took place. Having the input of a psychologist was extremely beneficial; she enhanced the management of behavioral symptoms, particularly depression. Another purpose of the team conference was to provide support to colleagues, because it was not uncommon for a team member to be visibly upset if an intervention was not as effective as anticipated or at the time of death. Debriefing, whatever the situation might be, is part of the process.

Open Access to Safe Conduct Team

In addition, patients and families could access the SCT phone line between 8:00 A.M. and 4:30 P.M., Monday through Friday. During off hours, families were directed in writing and prompted via voice message on the SCT phone line to contact their primary oncologist at all other times, as is normal practice at the ICC. During the established hours, patients and families knew that some member of the team would return their call if they did not immediately reach a team member. As a result, patients and families did not have to wait until the end of the working day, when physicians routinely return telephone calls. This open access to the team provided a certain amount of security. Because the team was monitoring these patients so closely, they were able to recognize subtle changes and encourage patients to come in to the clinic to be assessed and treated. It is likely that this careful attention to patients’ symptoms prevented more complex problems from occurring.

Bereavement

If the patient was not enrolled in a hospice program, family members were referred to a bereavement center for follow-up. At the time of death, families received a bereavement card signed by all members of the team. This followed the protocol of the ICC, where the primary oncologist writes a letter to families at the time of death. The members of the SCT also attended calling hours, memorial services, funerals, or shivas whenever possible if the patient lived in the Greater Cleveland area.

Interdisciplinary Team Dynamics

Going into the project, the Project Director, who was experienced in effecting change within systems, had preconceived ideas regarding the challenges to be faced. In reality, the greatest challenge was creating and maintaining a healthy, functioning team. Although the original members of the SCT, like the Project Director, came from HWR, they never represented hospice as such. It was their knowledge and expertise in end-of-life care, not their hospice affiliation, that created their identity. The other distinguishing feature was that the SCT was an interdisciplinary team, not a multidisciplinary team. On a multidisciplinary team, members are known first by their professional identify and secondarily by their team affiliation. On an interdisciplinary team, the identity of the team supersedes the individual professional identities. Members blend roles, share information, and work together with the patient and family to develop the patient’s goals.

In a period of 5 ½ years, the SCT has been recreated and rebuilt three times. The only persons who have remained constant on the team are the spiritual care counselor and the medical psychologist, who is a consultant to the team. The original nurse on the SCT was a home care nurse in hospice. Within a few months, it became apparent that the expectations of the role required an advanced practice nurse, because the nurse is expected to be an expert in pain and symptom management, to be capable of interfacing with oncologists as a colleague, to be able to teach pain and symptom management
to staff and physicians, and ultimately to be a change agent in the system.

Any time a person on the team changed, the team dynamics immediately changed and the team building started over. To enable the SCT to work effectively as a team and to enhance the integration of the team into the cancer center, they were located in the same physical environment inside the ICC. Each time the composition of the team changed, the newly created SCT was taken off site for a day of team building.

Many factors appeared to contribute to the challenge of having a healthy functioning team. This team functioned under a palliative care model, as opposed to a palliative medicine model. The difference is that a palliative care model is flat in regard to authority, and all disciplines within their scope of practice have equal input. The other distinction is that all disciplines are involved in development of the plan of care with every patient, who determines what the goals will be, rather than being involved at the discretion of another professional. Most professionals work independently; they have not had experience working closely on an interdisciplinary team, and that is the central issue. Repeated role modeling and mentoring were the techniques used to teach the individual team members how to use a holistic approach and how to blend roles. Some professionals are never comfortable working closely on an interdisciplinary team, because their practice becomes very transparent to their colleagues.

**Bridging the Gap: Creating an Interagency Interdisciplinary Team**

From the beginning, there were major differences in philosophy and experience between the original SCT from HWR and the ICC staff. Therefore, a proactive plan was established to address these differences. To illustrate, a member of the SCT said, “If the patient doesn’t want to eat, that’s okay.” That statement demonstrated lack of knowledge regarding aggressive treatments in an oncology center. The team member was responding from her own point of reference, when a patient is actively dying in a hospice program. She had no understanding of the role of nutrition for referred patients, the cost of drugs, and hospital and clinical trials.

Teaching and learning took place on both sides. The SCT visited a new patient who was on the research floor, where phase I clinical trials are conducted. The patient asked, “How do I tell my children I am dying?” This led to a conversation that resulted in the patient’s crying, a very appropriate reaction. The staff on the research floor interpreted the patient’s crying as evidence that the SCT had upset her. The other two areas requiring education for ICC staff were pain management (discussed earlier) and a better understanding of when hospice-level care was the appropriate level of care. A gray area for the ICC staff was how to recognize when it was appropriate to refer a patient to a hospice program. After the original bumps in the road, the gap between the two cultures narrowed as the SCT integrated into the ICC and became an interagency interdisciplinary team.

**Evaluation and Analysis of Data**

Project Safe Conduct was a demonstration project, not a randomized controlled trial. Therefore, it is difficult to respond to frequently asked questions that could be answered only if a randomized controlled trial model had been performed. What can be shared are the processes and outcome data and the impact on complex systems. The strength of the project was that almost an entire population of lung cancer patients was studied for a period of 2 years.

The tools administered were the short and long forms of the Wisconsin Brief Pain Index (WBPI); the Missoula-VITAS Quality of Life Version 15 (MVQOL-15), which measures patients’ quality of life on five dimensions; the FACT-L, which measures quality of life; and the After-Death Inventory (ADI), which measures family satisfaction. In addition to using these tools, the clinical researchers tracked the length of stay in hospice for referred patients, the cost of drugs, and hospital and emergency room admissions.

Pain was present in virtually 100% of the patients at some point, and it clearly interfered with their life and well-being. Regardless of the level of pain (worst, least, or average) there was an extremely high correlation between pain and the impact on mood and sleep.

The MVQOL-15 total scores correlated with patient quality-of-life ratings in five dimensions of the patient’s experience: symptoms, function, interpersonal relationships, well-being, and transcendence. A number of demographic characteristics were found to be associated with the quality of life and pain at baseline and at follow-up visits. The following subgroups of patients scored significantly lower on quality of life and higher on pain measures at baseline and at follow-up visits: young; African American; female; single, widow, divorced/separated, or unspecified marital status; and unemployed. Of these subgroups, all caught-up after 9 to 12 months except African Americans, widows, and those with unspecified marital status, who remained at high risk throughout the 1-year follow-up for selected quality of life and pain outcomes. The documentation of catch-up in the second 6-months of follow-up for the other high-risk demographic subgroups on both quality of life and pain outcomes was a positive finding. According to the statistician, it is highly likely that improvement in both quality of life and pain management was due in large part to the interventions of the SCT.

**Place of Death**

The most startling outcome was the shift in place of death. One of the goals of the project was to involve patients and families earlier in decision-making regarding end-of-life care. The 1997
statistics regarding lung cancer deaths for patients from the ICC were reviewed before the SCT intervention. Of the 149 deaths reviewed, 13% of patients with advanced lung cancer died with hospice support, with a median length of stay of 5 days and an average length of stay of 10 days. As of June 2001, when accrual of patients into the study was completed, 80% were dying with hospice support, with a median length of stay of 29 days and an average of 44 days. Eighteen months after the project ended, 75% of patients were dying with hospice support, with a median length of stay of 36 days and an average of 64 days. The majority of patients died in their own homes. Occasionally, patients were transferred to a hospice in-patient facility, based on the request of the patient/family when the patient had hours to days of life. These data speak to the sustainability of the intervention after the end of the demonstration project. To put these data into perspective, the national median length of stay in a hospice program is approximately 22 days and the average length of stay is 55 days, according to National Hospice and Palliative Care Organization statistics.4

A hospice referral is a process, not an event. Several factors contributed to moving patients to the appropriate level of end-of-life care. The members of the SCT who were experienced in palliative care knew how to guide the patient and family “through a maze of uncertain, perplexing, and distressing events” and build a trusting relationship. They were very comfortable in talking about hospice and engaging the patient and family into discussions about values, beliefs, treatment options or choices, goals, hopes, and unspoken fears. Shifting the level of care to hospice was viewed by all as an addition to the plan of care and not seen as taking everything away.

Second, the SCT was present at family conferences and provided support for the patient/family as well as the oncologist. One of the goals of the project was for the SCT to support the oncologists, especially regarding end-of-life topics. Oncologists should not be put in the position to have these conversations alone with families; they too benefited from the support of the SCT before, during, and after the news was delivered. Because of the integrative model of palliative care with the SCT, opening the conversation of end-of-life care was not viewed as withdrawing hope for these patients, but rather as part of the continuum of care at ICC. A referral to hospice was no longer seen as “giving up on” patients.

Open communication regarding palliative end-of-life care was modeled by the SCT in their daily practice with patients/families and the professional staff at the ICC. In addition, they were authorized to carry out their recommendations and interventions. This was the base for the professional staff to become comfortable with the topic and to build rapport with the patient and family. Patients were given options, and 25% chose to continue aggressive treatment until they died.

Other Comparison Data

Two other pieces of data were compared before and after the SCT intervention. The first was the number of hospital admissions and emergency room visits. Before SCT, the average number of hospital admissions or emergency room visits was 6.3 per patient. After the SCT became involved, that number decreased by 50%, to 3.1 visits per patient on average. A possible explanation for this decrease was the access patients and families had to the SCT through the team telephone number; team intervention prevented many emergency room visits.

The second piece of data was pharmaceutical costs. This information was an estimation of costs if all prescribed medications were filled (not including chemotherapy). Before SCT, the average daily cost per patient was $60.90, compared with $18.45 after SCT intervention. The advanced practice nurse worked very closely with the oncologists in managing pain and teaching pain management to fellows and some faculty who were less experienced. One of the outcomes of the project was a change in prescriptive patterns when doing pain management. More adjuvant medications were used, and high-cost opioids were not automatically prescribed but used only if appropriate.

Steps for Duplication of the Model of Care

Throughout this chapter, many of the essential elements of success have been identified. These elements are summarized in this section. Every system is different, so the identified steps for development of this integrative model of palliative care is the macro view; the micro aspects must be individualized according to the system.

Collaboration

- Support and buy-in from the top administrator who has control over daily operations is imperative. Do your homework well and do not attempt to implement the model until buy-in occurs.
- It is necessary to obtain buy-in not only from the top administrator, but also from the oncologists and staff who will be interacting daily with the team. The retreat off-site, where all oncologists and staff heard the same message about the project, was the beginning of buy-in for the oncologists. At all times, the message was that the oncologists do good work and the SCT is there to enhance their work and not add to it.
- Develop a steering committee, which meets every 4 months, to assist in addressing the direction of the project and developing overall strategies for implementation. The major decision-makers/implementers are at the next level.
- A trusting relationship at the decision-making/implementation level was the secret to Project Safe Conduct, beyond the more obvious ingredients. The Project Director was from HWR, and her counterpart was Vice President for Cancer Services at ICC. Those two individuals met weekly and developed a strong, trusting relationship as colleagues. The Project Director’s expertise was in end-of-life care, but,
needs assessment identifies late referrals or limited referrals as an area for improvement, this is easily measured.

- Physician surveys were done after about 6 months into the study to identify any unmet needs or problems that needed to be addressed.

### Safe Conduct Team Post-project

When the Robert Wood Johnson Foundation funded Project Safe Conduct as a demonstration project, one of many questions to be answered was how the ICC planned to sustain the program after the conclusion of the grant. The outcome of the project has been a new, higher standard of care. Removal of the SCT would be interpreted as a reduction in service, because this new standard of care has now become an expectation. As a result, the ICC is so committed to the SCT and the excellent work they have done that the members have been hired full-time at ICC. The cost of the team is integrated into the system and charged to the overall budget of the ambulatory ICC, with no additional fee charged to the patient/family. The Project Director, who also facilitated team conferences during the project, continues to facilitate the weekly conferences and support the team. Her time is donated as an in-kind service by HWR.

The composition of the SCT today is an advanced practice nurse with a background in palliative care, the same spiritual care counselor, and two social workers assigned according to disease entities. The target population has expanded to include patients with advanced gastrointestinal malignancies or advanced head and neck malignancies, as well as those with lung cancer stage IIIIB or IV.

The number of patients followed on any given day has increased from approximately 80 during the project to a set limit of 100. With such a large census, the SCT has had to develop a system to deliver palliative care that philosophically is unchanged but permits the involvement of more patients. Table 64–1 is an example of documentation used to identify and monitor patients.

Patients are referred to the team by oncologists, radiologists, nurses, and social workers. At every appointment, some member of the team tries to meet with the patient and/or family. In addition to the information on the patient record form, a daily schedule is prepared and the team decides which member will be the primary contact, depending on the needs of that individual patient. To illustrate, if a patient is having spiritual suffering, the spiritual counselor would definitely be the primary contact. But if, during a visit, the patient begins to talk about physical pain, then the spiritual counselor would page the advanced practice nurse to see the patient during the visit. The nurse practitioner sits in on physician visits so that she can be very involved as the disease progresses. At some point during the patient's course of treatment, team members from all disciplines sit in on doctors' visits.
Today, the SCT monitors patients as they did during the project, using a holistic approach to address pain and symptoms. The SCT continues to be involved in family conferences, with some of these conferences taking place in the patient's home. The main difference is that not all team members see the patient and/or family on every visit, and the length of time spent with the patient and family may be decreased.

The clinical researchers for Project Safe Conduct astutely incorporated the following key concepts into the program design: a well-defined vision aligned with the organizations’ missions; a detailed, comprehensive plan; clinical and administrative leadership endorsement and staunch support; family conferences initiated by any team member or by the patient or family; and the integration of palliative care into routine operations.

### REFERENCES

Harlem Palliative Care Network*

*The Harlem Palliative Care Network is a community based palliative care partnership among Memorial Sloan-Kettering Cancer Center, North General Hospital, and the Visiting Nurse Service of New York.

Imagine that you are the 51-year-old, Spanish-speaking, single mother of two children, 11 and 13 years old. You have bilateral breast cancer; you are in extreme pain, and your body is distorted with edema. Your lifelong belief in spiritual healing is no longer helping to relieve the pain and fight the cancer. Your children have no bedroom furniture and are sleeping on mattresses on the apartment floor. Your family, which includes a male companion, is threatened with eviction from your East Harlem, New York, apartment. In fact, the electricity has already been turned off. You are too ill to work. Your health insurance has lapsed; your family does not have enough food. You will die in 276 days. Among other issues important to you in your care is the fact that you want to die at home.

In the summer of 2001, Ms. S was referred by her oncologist at North General Hospital (NGH) to the Harlem Palliative Care Network (HPCN), a community-based model of palliative care that was made possible by a 3-year grant from the United Hospital Fund (UHF). The UHF selected this partnership as one of six community-oriented palliative care initiatives and provided valuable financial and consultative support for the duration of the project. HPCN enjoyed additional support from the James N. Jarvie Commonweal Service, a long-time supporter of the Visiting Nurse Service of New York (VNSNY), and generous in-kind contributions from NGH, VNSNY, and Memorial Sloan-Kettering Cancer Center (MSKCC).

From 2000 until 2003, HPCN served 350 predominantly female patients, age 20 to 91 years, who were residing in East and Central Harlem and had one of the five target diagnoses: progressive cancer, congestive heart failure (CHF), chronic obstructive pulmonary disease (COPD), end-stage renal disease (ESRD), or HIV/AIDS. This chapter describes the partnership, the care model including the network, and the success of HPCN. The legacy of the HPCN is a community-based palliative care model that demonstrated reduced pain and suffering, increased the number of patients with advance planning, and improved quality of life (QOL).
Harnessing the Power of the Partnership

VNSNY is the preferred home care provider for both MSKCC and NGH and operates one of the largest hospice programs in New York City. VNSNY has well-developed programs to better meet the needs of the culturally and ethnically diverse populations of New York City. NGH is the primary site for serving the acute care needs of Central and East Harlem residents and provides two converted patient rooms as office space for HPCN operations. NGH has extensive knowledge of community needs and resources as well as strong relationships with community-based organizations and providers. MSKCC is an internationally renowned cancer treatment and research facility that provides patient care and clinician training on all aspects of oncology, including pain management and end-of-life care.

The UHF grant enabled the partnership to establish a core staff and begin assembling a community-based network that numbered more than 100 providers. All three partners played key roles in developing the network. Network providers were selected based on their ability to meet a category of patient need. All agencies experience capacity issues at one time or another, and for this reason HPCN sought a few providers in each category. This was not always easy or even possible.

Network members provided a variety of services and included churches, health care providers, support groups, and other organizations. The Table 65–1 below provides examples of needs addressed by the Harlem Palliative Care Network in each of the domains.

pharmacies, pharmaceutical companies, and soup kitchens. They addressed needs in five domains: pain and symptom management, social/psychological/emotional, spiritual, physical, and advance planning. Examples of patient needs in each of these domains are presented in Table 65–1.

Examples of matching needs, solutions and network providers can be found in Table 65–2. Table 65–3 lists sample services for several categories of providers. Network members received end-of-life care education. Organized outreach included one-on-one appointments, educational presentations, and mailings to network members of current literature on palliative care designed to increase competency in end-of-life care. In addition to receiving referrals from HPCN, providers were asked to be aware of people in their community who needed palliative care and to refer those people to HPCN. The topic of advance planning was introduced within the first week after entry into the program. Multiple conversations addressed the topics of proxy, comfort, treatments, and relationships with loved ones. These conversations took place with patients and families by the HPCN staff.

### Establishing a Barrier-Free Palliative Care Program

Understanding the community was the first priority. Beliefs about end of life have deep roots in culture, religion, and clinical practice patterns. HPCN sought to understand these beliefs and practice patterns, present the project’s vision, and refine that vision to match the needs of the community. HPCN worked synergistically with other initiatives in the community, such as the Initiative to Improve Palliative Care for African Americans (IIPCA) and the Ziegler Professional Education Project (ZPEP), and a Nathan Cummings Foundation Grant. This initial process consumed the first 6 to 8 months of the grant and was time well spent.

First, a multidenominational clergy focus group helped to identify needs, learn about religious implications in end-of-life care, and educate clergy on palliative care. The clergy often know when a member of their congregation is facing a life-limiting illness and are in a key position to identify palliative care patients and refer them to NGH or directly to HPCN.

Second, HPCN participated in a Latino workgroup whose members reflected the growing Hispanic-Latino demographic in East and Central Harlem. The group comprised local community leaders, clergy, and medical providers and served to gather input from and effect change in the Latino community’s perception of NGH. East and Central Harlem residents perceived NGH as a primarily African-American institution. A plan was adopted to infuse the community with an image of NGH as a community hospital that welcomes Hispanics and Latinos. A concrete example of the changes was a commitment on the part of the hospital to increase community outreach and to develop bilingual signage and staffing.

Third, key opinion leaders were invited to join the ongoing Community Advisory Board for HPCN. This platform provided continued community visibility for HPCN, and for palliative care in general, and feedback throughout the 3 years during which HPCN was serving the community.

Fourth, there was organized outreach to physician offices, clinics, and other community-based organizations. This outreach included one-on-one office appointments by the VNSNY Physician Relations staff, group and dinner presentations supported by pharmaceutical companies, and mailings to network members with current literature on palliative care that was designed to increase competency in end-of-life care. During the first 2 years of the project, the message of HPCN and palliative care was brought to a total of 4000 people.

Fifth, the steering committee for HPCN met regularly and consisted of decision-makers in senior clinical and business management positions at each of the three partner organizations (MSKCC, NGH, and VNSNY). Through these efforts, the steering committee concluded that this underserved community faced common progressive diseases such as cancer, heart disease, COPD, and AIDS. Many of these people died without palliative care services available to them or their caregivers and families. Rather, they died in fear and discomfort after long struggles with uncontrolled pain, unresolved grief, and other daunting symptoms. In addition to economic factors, barriers to the delivery of palliative care included lack of knowledge or clinical expertise, hesitation on the part of providers to prescribe medications that might help feed a local network of illicit drugs, and a curative culture that still undervalued symptom management and psychosocial support. On the patient’s side, barriers included cultural beliefs, a distrust of the health care system, financial hardship, and a lack of insurance coverage, which impeded access to the supportive services that could improve their QOL.

The staffing model for HPCN included a director, a clinical coordinator, and an administrative assistant. In the start-up months, the roles and responsibilities of program staff were blurred. As the program evolved, these roles were clarified to achieve operational efficiencies. Over the 3 years, the skill set needed to advance the project changed, and this necessitated personnel changes to be successful and develop the program.
This model relied on in-kind resources from the partners to provide administrative support for accounting, human resources, clinical leadership and strategic planning, outcome analysis, and reporting. When hiring, HPCN sought cultural and linguistic matches. The program was bilingual (English/Spanish) and produced patient education literature in both languages. HPCN was located in NGH, in two converted patient rooms on the same floor as the oncology clinic. This provided convenient access for patients in a familiar setting and ease of patient travel to HPCN during physician visits or outpatient chemotherapy sessions. The clinical coordinator was called for bedside consultations on inpatients. With a lean staff and complex cases, the network became a key partner in meeting the needs of the patients.

Patient Care

To ensure a barrier-free environment, the admission criteria were as broad as possible. Every referral was accepted. In the rare instance in which a patient was not accepted into the program, the patient was linked to a more suitable provider. Examples of patients not enrolled in the program are persons younger than 18 years of age and those with chronic pain related to fibromyalgia. Characteristics of the enrolled patients are presented in Tables 65–4 through 65–6.

A nurse or social worker assessed each patient on referral. Data collected included demographics, information on the caregiver, proxy, diagnosis, medications and knowledge of illness, and identified barriers that made it difficult for the patient to comply with the prescribed medical regimen. Of greatest importance was how this diagnosis was affecting the QOL for the patient. A pain and symptom assessment, based on a 10-point scoring system, and the Missoula Vitas Quality of Life Index (MVQOLI) completed the initial assessment. This triad of data collection enabled the HPCN professional staff to outline a plan of palliative care designed to improve the patient’s QOL in the physical, social/psychological/emotional, spiritual, and pain and symptom management domains. This interview session laid the relationship groundwork for sensitive discussions concerning advance planning.

The MVQOLI was repeated every 60 days. The pain and symptom assessment was repeated as needed, but at a minimum every 60 days. HPCN’s success in advance planning, pain management, and improving QOL is discussed later.

Social Work Versus a Nursing Model

During the first 2 years of the project, the clinical coordinator was a nurse. Review of the data after 2 years revealed that the interventions this population needed most were primarily social in nature (Table 65–7). For the remaining year, the clinical coordinator role was cast as a social worker, with a part-time nurse available to address the clinically frail patients and to collaborate with the social worker on patients with nursing needs. The average daily census was about 90 patients. This enabled all program staff to know the needs and goals of each patient and to work collaboratively when each needed the expertise of the other. A close collaborative relationship between the nurse practitioner and the physician in the oncology clinic, and the close proximity of HPCN offices to the oncology clinic, provided HPCN staff effective access to these professionals when pain and symptom management required their intervention.
Harlem Palliative Care Network

The Plan of Care

A plan of care was created that linked each patient to network providers with the ability to meet that patient’s needs and to improve the QOL for that patient. Once the patient was socially stable, there was a sound foundation on which the medical team could build the medical plan of care. Patients’ problems compete with their ability to be compliant with plans of care laid out by the medical team.

Network providers were linked to a patient to help satisfy an identified need. Sometimes it was as simple as discussing with the clinic staff the scheduling of appointments. In one case, HPCN coordinated doctor visits so the patient did not have to choose between lunch at the soup kitchen or a visit with the doctor. Patients dealing with guardianship of minor children were connected to the Legal Aid Society. Families needing counseling were connected to the Family Center. The HPCN plan of care involved the patient and family, the medical team, and, when appropriate, the Network.

Advance Planning

The HPCN model of palliative care required identifying the needs of patients concerning advance planning and meeting those needs. This process was central to the HPCN mission. Even so, we stumbled. The reasons are not surprising. Becoming comfortable with these frank discussions was a skill set that the team needed to develop. It was much easier to meet a concrete need such as pain management. Even conversations about subjects as basic as the health care proxy were not resulting in decisions from the patients. We realized that patients do not approach advance planning in a linear fashion. After much internal discussion, the following process emerged. HPCN staff could engage the patients in discussion that naturally segued into identification of a health care proxy, completion of a living will, or creation of a do-not-resuscitate document. As this strategy was implemented, data were collected on the next 111 patients. The staff recorded strategies that the patients responded to. The ways in which patients were engaged are described in Table 65–8. Many patients eventually discussed more than one topic.

However, different topics resonated with individual patients. The clinician needed to find a common ground with the patient to introduce advance planning. Even if no document resulted from these interactions, when these patients were faced with a document to sign on admission to the hospital, their wishes had already begun to form and they were not making decisions about goals of care in a crisis. It took about eight sessions with the HPCN member to establish a relationship in which advance planning conversations were effective and not so emotionally charged for the clinicians, patients, and families.

A fair number of patients were undocumented immigrants, with better family and social support in the country of origin. Some of these patients chose to return to their country of origin for death. For some patients, HPCN assisted with funeral planning. After evaluating multiple resources and tools, HPCN

adopted the Five Wishes document for use in patient education on end of life. This 12-page document is available in English and Spanish through the Aging with Dignity organization at their website (http://www.agingwithdignity.org).

The Outcomes and the Legacy

The HPCN model demonstrated that QOL can be improved and suffering relieved even in patients who proceed to death. Patients began to see advance directives as empowering and not as withholding of treatment. For those patients who did not complete advance directives with HPCN, the staff unanimously felt that the patient was overall prepared to make those decisions when required in urgent situations. Internal analysis of the advance planning data revealed a 39% increase in the number of patients engaged in the advance planning process (Table 65–9). In addition, the location of death was reviewed as an indicator of patient control over care at the end of life (Table 65–10).

Quality of Life

HPCN collected and acted on quality-of-life information every 60 days, using the MVQOLI. HPCN submitted multiple MVQOLIs on the first 117 patients. The tools reflected an 8-month period in the patient’s life. The MVQOLI is designed to measure the subjective, experienced QOL of patients with advanced illness. Patients provide their own responses; QOL is not staff-assessed. Therefore, the data reflect the patient’s experience of his or her own QOL in the five domains measured (Figure 65–1).

The instrument measures five dimensions of a person’s subjective experience: symptoms (SX), functional status (F), interpersonal relations (IP), emotional well-being (WB), and transcendence (TR). Within each dimension, three types of information are elicited for patients:

1. An assessment of perceived status with respect to the experience encompassed by the dimension
2. The degree of satisfaction or dissatisfaction with the status
3. A rating of the importance of the dimension to overall QOL

A unique scoring protocol devised for the instrument allows for the weighting of each dimension based on the importance assigned to it by the patient.

Cumulative data for all patients over the 8-month period showed the following:

1. On average, patient-reported QOL increased.
2. Patient-reported QOL increased during the first 60 days of care.
3. QOL remained high or continued to increase for the entire 8-month period.
4. Patients who came to HPCN with the lowest QOL showed a 50% increase in QOL scores on the MVQOLI within the first 60 days of care.
5. Improvements were seen in all domains—symptoms, function, interpersonal, well-being, and transcendent. The most dramatic improvements were seen in the emotional well-being and spiritual (transcendent) domains.

Pain Management

Routinely, patients were assessed for their pain levels at a minimum of every 60 days and as indicated. In addition, 48 hours after a change in the pain medication regimen, the pain score was reassessed. Patients were taught to communicate their pain to physicians and HPCN staff using the 10-point pain score. An outside evaluator for UHF found the reduction in pain scores to be significant.

Sustainability

Efforts were heroic to secure additional funding for continuation of the HPCN, but to no avail. The funding after the September 11, 2001, terrorist attack in New York City was very limited. The message from funders was clear: They were...
interested in programs that provided a broader reach to affect more patients. What could we take away from our HPCN work and reach more people? VNSNY Hospice Care has been successful in securing funding focused on increasing competency in palliative care and increasing the reach of programs such as HPCN. A consultation team based in VNSNY Hospice Care will lend expertise to nurses in the VNSNY Certified Home Care Agency. The team will provide an array of services that reflect the three core competencies of hospice and palliative care: advanced care planning, pain and symptom management, and counseling. In addition, the consultation team will design strategies for early introduction of palliative care and will also offer care coordination services.

The lessons learned from the HPCN model were powerful:

1. Match the staff with the ethnic backgrounds of the patients.
2. Understand the cultural implications of end-of-life decision-making.
3. Provide support for the social, psychological, and spiritual needs of the end-of-life patient to provide a steady platform for medical management of the pain and symptoms related to the terminal diagnosis.
4. Educate time and again the health professionals, clergy, and community-based agencies. Two components are essential to this education: the academic

![Figure 65-1. Results of administration of the Missoula Vitas Quality of Life Index (MVQOLI) at 60-day intervals to 117 patients. The instrument measures five dimensions of a person’s subjective experience: symptoms (SX), functional status (F), interpersonal relations (IP), emotional well-being (WB), and transcendence (TR).]
material and the experience gaining comfort with end-of-life conversations.
5. Integrate palliative care into the medical plan of care.

Reimbursement

VNSNY is actively working with managed care organizations to make the clinical and business case for palliative care services in the hospice contracts. Palliative care at this time relies heavily on philanthropy. The data on cost savings of palliative care in health plans are mounting. There is evidence in the literature that emergency room visits are decreased, hospital stays are shortened, and pharmacy costs are decreased when palliative care is introduced.4

Setbacks and obstacles can be overcome if the program sets clear goals and focuses on achieving results. Although there were changes in personnel and reporting relationships, the program never lost sight of its goal to improve the QOL for Harlem residents facing life-threatening illness. The program strove to touch the lives of an increasing number of patients in need and to understand how to effectively meet those needs and overcome barriers to access.

ACKNOWLEDGMENTS

The HPCN received initial funding from the United Hospital Fund and additional support from the James Jarvie Commonweal Service. NGH, MSKCC, and VNSNY provided generous in-kind support throughout this project.

We thank others who contributed to the success of the HPCN: Terri Payne, Lisa Alvarenga, Sam Daniel, Elaine Keane, Jennifer O’Neill, Oscar Lewis, Liz Alvarado, Norma Castillo, Enol Onda, Roberto Rodriguez, Joseph Yo, Jenny Romero, Barbara Coulston, Nessa Coyle, Diane Magnuson, and Susan Hopper.

REFERENCES

Canadians highly value their publicly funded health care system and believe that quality end-of-life care is an imperative. Indeed, end-of-life care is consistent with the very values that resulted in the creation of a national health care system. However, the current system of end-of-life and hospice palliative care in Canada has been described as a patchwork of inadequate and inequitably available services. Access to services is influenced by the diseases Canadians die from, whether they live in a city or rural area, the province in which they reside, the nature of their health insurance plans, and their personal wealth. Only 5% to 10% of the 220,000 Canadians who die each year receive integrated and interdisciplinary palliative care. The estimated cost of dying in Canada is approximated at $3 billion annually, with no performance indicators to suggest that resources are appropriately allocated. Recent federal reports are calling for federal action to address access to palliative care services, particularly in the home. The increased attention on end-of-life care and acknowledgment that services are inequitable challenge those responsible for health services delivery to develop initiatives and to address models of care for palliative care delivery.

This chapter discusses models of service delivery for palliative care in Canada. To provide context to Canada, an overview of the Canadian Health Care System is provided. The responsibilities of the federal and provincial governments and regional health authorities are described, as these three levels of government are accountable for health care delivery. The impact of the Canadian Hospice Palliative Care Association (CHPCA), in particular the consensus-based Model to Guide Hospice Palliative Care, is presented. Key factors influencing program development are discussed: the end-of-life care movement; the shift to community-based care; the unique needs of rural Canada;
cultural factors; and primary health care. The challenges and direction of best-practice model development is analyzed. Programs in Edmonton and Calgary are discussed as examples of integrated regional community-based programs.

Responsibility for Palliative Care

Federal Government

Health care in Canada is publicly funded and universally accessible. The Canada Health Act is federal legislation that facilitates reasonable access to health services without financial or other barriers through the five key principles of public administration, comprehensiveness, universality, portability, and accessibility. While the Constitution Act of Canada (1982) defines health care as a provincial rather than federal responsibility, in practice, responsibility for health care is shared between the federal and provincial governments. The federal government can influence health care through legislation and control of financial resources. The federal government can also impact areas of health care through regulations, commissions, and activities of its various departments. For example, Health & Welfare Canada has initiated several key reports and meetings that have increased national discussion about health care and end-of-life care issues (Table 66–1).

All reports call for national initiatives to increase access to integrated palliative care services, with particular emphasis on palliative care services in the home. This is crucial to the development of palliative care in Canada because the Canada Health Act is generally viewed as a barrier to community-based palliative care. The principle of “comprehensiveness,” as defined in the Act, includes only health care provided in hospitals, or by physicians in any setting. Thus, each province decides which additional services, if any, will be funded. The result is that home-care coverage varies between provinces and within regions of a province. To address this inequity, the Commission on the Future of Health Care in Canada specifically identified this issue and proposed that new home care transfer payments should be used to support expansion of the Canada Health Act to include medically necessary home care services, including palliative home care services to support people in their last 6 months of life.

In 2001, the federal government established the Health Canada Secrétariat on Palliative and End-of-Life Care in recognition of the need for a national action plan to ensure that all Canadians have access to quality end-of-life care. Five national working groups have been established to work on the priorities identified in a National Action Planning Workshop: Best Practices and Quality; Public Information and Education; Education of Care Providers; Research; and Surveillance. An example of improving quality of care is the Best Practice working group’s initiative with the Canadian Council for Health Services Accreditation (CCHSA) to incorporate palliative and end-of-life care into recognized quality assessment and improvement processes in Canada. They plan to develop a national set of standards and to incorporate them into the existing CCHSA health service standards. Furthermore, there are plans to develop a national accreditation program for free-standing hospice organizations and volunteer-based programs, which currently have no national method of accreditation. The development and integration of national palliative care standards into the CCHSA accreditation process will challenge health care providers to ensure that they have incorporated hospice palliative care services into mainstream health care services.

The Secrétariat was influential in the development of the Employment Insurance Compassionate Care Benefit, which was launched in January 2004, to ensure that Canadians do not have to choose between keeping their jobs and caring for their families. Canadians who must be absent from work to care for a gravely ill family member will be eligible to receive up to 6 weeks Compassionate Care benefit.

Provincial Government

Provinces have begun to recognize palliative care as a part of basic health care services. Some, such as Manitoba and British Columbia, acknowledge palliative care as a core health care service. Others, such as Saskatchewan and Alberta, have developed provincial guidelines for services. British Columbia has developed a provincial strategy for end-of-life care. Quebec has begun to integrate palliative care into its existing local community centers known as CLSC, supporting home care with a dedicated phone line and on-call physicians, nurses, and pharmacists.

Barriers to accessing medications in the home are being addressed by some provinces. For example, several provinces will now cover the cost of palliative medications such as opioids and laxatives for persons who are designated as palliative by their physicians (British Columbia also provides coverage of equipment such as hospital beds and supplies). Canadian physicians have adequate access to a wide variety of angesics for pain management and do not have to contend with the daunting regulatory impediments faced by care providers in many other countries.

There is increasing recognition of the need for adequate reimbursement for family physicians to provide home visits, spend the necessary time with patient and family, work with team members, and provide 24-hour coverage. However, only a handful of provinces have addressed palliative care codes for physician remuneration.

Regional Health Authorities

In the 1990s, most provinces in Canada partially devolved their responsibility for health care to sub-provincial regions in an effort to streamline the delivery system, making it less fragmented and more responsive to local needs. Regional Health Authorities are autonomous health care organizations with responsibility for health administration within a defined geographic region within a province or territory. They have appointed or elected boards of governance and are responsible

for funding and delivering community-based and institutional public health services within their region.\(^\text{15}\) To date, all provinces and territories, other than Ontario and the Yukon Territory, have implemented some form of regionalization.\(^\text{15}\) The process of regionalization has, in most areas, resulted in a decrease of acute care beds, as the community and acute care sector begin to become more integrated.

In Wilson’s\(^\text{16}\) synthesis research project, she identified that, in theory, regionalization has the potential to assist integration of end-of-life care by facilitating access and care continuity across diverse health care settings. Alternatively, regionalization could limit growth of palliative care services if particular regions do not see palliative care as a priority. The need for research to substantiate whether the theoretical benefits of regionalization are actualized is evident.

The Canadian Hospice Palliative Care Association\(^\text{17}\) is the national nongovernmental organization that provides leadership for hospice palliative care in Canada (CHPCA, 43 Bruyère Street, Suite 131C, Ottawa, Ontario K1N, 1-877-203-4363 [toll free], info@chpca.net). Founded in 1991, its mission is to promote awareness, education, and research, advocating at a national level for policy development, resource allocation, and support for caregivers. The CHPCA board of directors is composed of the 11 provincial/territorial associations and five members-at-large. Advocacy is an important role for provincial and federal counterparts. The CHPCA chairs the Quality End-of-Life coalition, taking leadership in the advocacy role.

Historically, the terms “hospice” and “palliative care” were used in Canada in a variety of ways. The term hospice may have indicated a philosophy of care, a free-standing building, a unit in a long-term care facility, or a home-based program. New terminology in Canada was proposed in 2002. The words hospice and palliative care were combined to recognize the convergence of hospice and palliative care into one movement. The national organization for palliative care adjusted their name to include the term “hospice palliative care.”\(^\text{17}\) Their updated definition is “Hospice palliative care is aimed at relief of suffering and improving the quality of life for persons who are living with or dying from advanced illness or are bereaved.” It is appropriate for any person and family living with a life-threatening illness due to any diagnosis, regardless of age and prognosis.\(^\text{17}\) This definition calls for hospice palliative care intervention earlier in the disease trajectory for all diagnoses.

A priority of the CHPCA has been the development of national standards to guide the development of palliative and hospice care service delivery across the country. Following 10 years of extensive consensus building and collaboration across Canada, a model to guide hospice palliative care was published in 2002.\(^\text{18}\) The model is comprised of: the values, principles and foundational concepts that underlie all aspects of hospice palliative care; a conceptual framework for the delivery of care called the “Square of Care”; and a conceptual framework to guide organizational development and function called the “Square of Organization” (Figure 66–1).

The CHPCA has also been an active partner in the establishment of palliative care as a specialty within the Canadian Nursing Association. The CHPCA Nursing Interest Group provided the venue through which nurses across Canada collaborated to

establish the Hospice Palliative Care Nursing Standards of Practice, which were developed in 2002. These standards and the CHPCA Model of Care provided the foundation for the development of palliative care nursing certification. The first sitting of the certification occurred in April 2004. More than 500 nurses are registered, the highest rate of enrollment of any certification process to date.

**Forces Influencing Model Development**

**End-of-Life Care for All**

Palliative care services in Canada developed with a specific focus on care of persons with cancer. However, the significant changes in Canada’s demographics are changing attitudes. The declining birth rate, development of new technologies, and increased life expectancy have resulted in an aging population, with a burgeoning baby-boomer population that will reach retirement in the next decade. The aging of Canada’s population has drawn attention to the necessity of an end-of-life care strategy that will address the needs of the increasing proportion of elderly who die every year from causes other than cancer. Currently, cancer patients receive 90% of the available palliative care services, although they only represent 25% of those who die. Deaths due to progressive chronic illnesses such as congestive heart failure, chronic obstructive pulmonary disease, renal disease, and dementia will increase. Recent hospice palliative care literature is replete with articles acknowledging the benefits of the hospice palliative care approach to individuals dying from diseases other than cancer. Authors have written about the need for integration of hospice palliative care into settings such as intensive care units and nursing homes, and to extend palliative care to those with diseases such as end-stage renal disease, cardiorespiratory disease, neuromuscular disease, and AIDS. It has been argued that hospice palliative care programs are providing service to a privileged minority—the ethical case for palliative care beyond cancer is resounding, and restricted practice is indefensible. MacDonald describes a Canadian paradox, in which we are facing growing numbers of elderly and people with chronic life-threatening illnesses during a period of continued downsizing in the health care system, while, at the same time, societal expectations for access to excellent care are rising.

Palliative care programs will be challenged to respond. Many of the characteristics of progressive chronic illnesses, such as prognostic uncertainty, do not “fit” with the admission criteria of many programs that have evolved based predominantly on a cancer model. Primary care professionals and palliative care clinicians, for the most part, have not developed expertise in the management of these conditions. Human resource issues are a critical concern. Shared Care models and partnerships with other clinical specialties are beginning to be established to address care for this broader group.

The end-of-life movement has compelled Canadians to address a variety of issues such as advance directives and euthanasia. Advance directives, or living wills, are beginning to gain attention. Provinces such as Newfoundland, Alberta, and British Columbia have passed legislation to compel health care providers to follow the previously written wishes of persons in the event that they are unable to speak for themselves. The “Let Me Decide” initiative, which began in Ontario, is being replicated in nursing homes in other provinces and areas.

**Shift to Community-Based Care**

During the initial development of palliative care in the 1970s and 1980s, health care was strongly institution based. In fact, Canada’s first palliative care programs were established in tertiary hospitals. In the mid-1990s, up to 80% of total Canadian deaths occurred in hospitals. We are now beginning to see a reversal of the trend toward dying in hospital. Growing numbers of patients, families, care providers, and planners are now advocating for increased community care and more opportunities for home deaths. The move to community-based care is seen as appropriate and fitting for palliative care.

Most palliative patients do not need to be in acute care hospitals, and quality palliative care can be provided in a home or hospice setting. However, the issue of transferring the cost of care from hospitals to persons and families has not yet been adequately addressed in most settings. People cared for at home may assume responsibility for the costs of medications, supplies, additional home care services, and transportation. In some provinces, persons pay a daily fee for hospice care. This fee is usually set at a rate similar to the nursing home accommodation charges.

Recent evidence suggests that dying at home may be idealized and, when family members actually have to face the challenges of care, the burden can be considerable. Indeed, the shift of care from hospital to home presupposes that care providers will be available in the home. Most programs do not fund 24-hour care over the long term, and there are regional differences in availability of home support. Unless families are able to afford private funding of care providers, the burden of care falls to family and friends. Although many Canadian palliative programs advocate for care in the home setting, there are several potential concerns to be considered. Canada has smaller family sizes, leaving fewer children to care for the wave of aging “baby boomers.” Children often live far away and work outside of the home. Spouses are elderly and have their own health issues, and early discharge from acute care means more care is expected from both home care and family caregivers.

There remains insufficient research into the issues and outcomes of caring for family members at home. Since we are likely to see increasing demands for home-based care, in part because of economic pressures in the Canadian health care system, solid research investigating all aspects of such care is needed.

Palliative care needs to reflect a continuum of services that incorporates community-based options such as home care.
and residential hospice environments. In many communities in Canada, grass-roots, donor-based organizations have taken the initiative to develop programs, such as free-standing hospices, to address this need. As more publicly funded palliative care services are developed, collaboration and integration with the voluntary sector is paramount.

Meeting the Needs of Rural Canada

In the past 5 years, there has been an increasing awareness of the need to ensure that the health care needs of rural Canadians are reflected in national health policy and health system renewal strategies. There is a considerable body of research that indicates a marked urban–rural difference in the provision of health care and social services. This inequity extends to the provision of palliative and hospice care.

Depending on which definition of rural is used, up to 30% of Canadians live in rural communities. Ninety-five percent of Canada’s territory is considered rural. The rural, Northern, and Aboriginal communities that comprise rural Canada have diverse social, geographic, and economic characteristics that challenge several of the key guiding principles of hospice palliative care, in particular, the principle of access. Rural communities face an acute and persistent shortage of health care providers. Rural practitioners must function as generalists, having limited access to specialist physician services and to the full interdisciplinary team available to urban counterparts.

The restructuring and reform of health care have resulted in downsizing and closure of rural hospitals and long-term care facilities, which provided an important infrastructure for rural health services delivery. Timely access to health care service is a significant challenge. A study of referral patterns to a central palliative care service in Halifax, Nova Scotia, found that people were more likely to be referred if they were younger, receiving radiation therapy, or lived closer to the center.

In their interviews with rural health personnel from six regions in Canada that were noted for their significant initiatives in rural health, MacLean and Kelley identified the following themes as critical to the development of rural palliative care models:

- Be sure the philosophy, definition, and guidelines of palliative care retain and reflect the “essence and strengths of ruralness.”
- Build on the strengths and experiences of people in rural areas rather than imposing a program from the outside.
- Build in flexibility and creativity to facilitate access to services.
- Ensure 24-hour access to specialist services through the most cost-efficient methods.
- Enable flexibility and “blurring” in regard to the boundaries between disciplines, job descriptions, and health care practice.

Several recent web-based innovations in Canada will help to address some of the challenges experienced in the provision of rural palliative care. In 2001, Health Canada announced funding to support the development of the Canadian Virtual Hospice (CVH). CVH goals are to facilitate, via a web-based forum, equitable distribution of mutual support, the exchange of information, communication and collaboration between and amongst healthcare professionals, researchers, the terminally ill and their families.

In December 2003 the federal government committed funding to a national outreach education and professional development initiative called the Pallium Project. The project aims to improve access, enhance quality, and provide additional capacity for palliative care in communities across Western and Northern Canada. Web-based technology is one of several strategies. Pallium is the first large-scale initiative to implement the CHPCA norms across several jurisdictions.

Impact of Culture on Models of Care

Canada is a rich tapestry of cultures from around the world. The four main cultural groupings include the Aboriginal peoples, British and French “founders” of Canada, and more recently, immigrants from Asia, Africa, and other non-European nations. The larger urban centers in Canada, where the “third wave” of immigrants from Asia and Africa as well as an increasing number of Aboriginal people tend to settle, are challenged to respond to the linguistic and cultural diversity. Palliative care practitioners are particularly challenged by this diversity on several fronts. In regard to access, research has suggested that ethnic minorities are underrepresented in palliative care programs. Access is further compromised due to the lack of translated materials and clinical assessment tools. The foundations of the modern palliative care/hospice movement are based on Christian tradition and teachings and a growing recognition of the futility and indignity of continuing expensive and intrusive treatments for people who are clearly dying. Guiding palliative care principles are based on the western ethics of “truth telling” and patient autonomy. These principles are often in direct conflict with the beliefs and values of many of the persons that we care for, resulting in culturally insensitive decisions and health policies. Palliative care programs in Canada need to reflect cultural competence. That is, we must reflect values, behaviors, attitudes, knowledge, and skills that are respectful and inclusive of diverse cultural backgrounds.
Impact of Primary Health Care

Canada is focused on the restructuring of primary health care delivery in response to a widespread call for health care reform to ensure a sustainable health care system. Over the past 2 years, $800 million was provided through the Primary Health Care Transition Fund to investigate models of primary care delivery. In 2003, the federal, provincial, and territorial governments signed a “First Ministers Accord of Primary Health Care” that included a 5-year, $16 billion commitment to improve primary health care. Primary health care is defined as a set of universally accessible first-level services that promote health, prevent disease, and provide diagnostic, curative, rehabilitative, supportive, and palliative services. The effects of primary care—responsiveness, effectiveness, productivity, accessibility, continuity, and quality—are expected to be enhanced.

Primary care initiatives have the potential for positive impact on the delivery of community-based palliative care in Canada. Family physicians will continue to be key providers of these services. Strategies that discover ways to re-engage family physicians in providing quality end-of-life care are critical to the sustainability of community-based palliative care services.

Models of Palliative Care Service Delivery

Literature on model development in Canada and elsewhere remains largely in the descriptive stage. There are several challenges in regard to evaluating palliative care models in Canada. First, while there is consensus regarding the philosophy of palliative care, there is not consensus regarding the operationalization of the philosophy. There is debate regarding who should be “palliative,” or when this designation should occur. Second, nationally accepted outcome indicators have not been developed or agreed upon. Much of the literature describes quality of life and satisfaction as appropriate evaluative methods for determining effectiveness of models of care, yet it is not clear what constitutes quality palliative care. Therefore, there is no agreement on how to evaluate effective palliative care services. The inadequate description of services using comparable variables does not provide evidence beyond a descriptive level or allow assessment of external validity or generalizability. The gaps in the literature make it difficult to understand what programs are currently in place across Canada, what the trends are, and what has been successful thus far.

The CHPCA conceptual framework, the “Square of Care,” will assist Canadian programs in developing a care model and providing a broad framework to evaluate the outcomes. The framework supports a standardized approach to ensure that all caregivers are knowledgeable and skilled, to identify gaps and opportunities for partnerships, and to ensure programs manage activities, resources and functions consistent with its approach to care delivery. The challenge to programs is to use the Square of Care, ensuring that the underpinnings of model development of accessibility and continuity of care are addressed. This will involve clear definitions, common language, assessment tools, and criteria of admission that meet national and local needs.

Best Practice Model Development

It is generally agreed that service delivery models for palliative and hospice care need to include essential components such as pain and symptom management, interdisciplinary teams, consultation services, psychosocial/counseling care, spiritual care, and volunteer and bereavement programs. Services to support care in the community include outpatient clinics, day care, respite care, hospice (home support, freestanding, and integrated into long-term care facilities), and community consultation teams. A seminal report to address model delivery of these components was provided by the Expert Panel of Palliative Care. Their report to the Cancer 2000 Task Force (responsible for providing recommendations on priorities and coordination for cancer to national cancer agencies) strongly recommended support of development based on regional plans. The report contained essential components such as home-based care, acute care, chronic palliative care beds, consultation services, and a tertiary, regional unit that would act as a learning and research center. The development of secondary and tertiary levels of care are necessary for the collaborative management of complex cases and for the much-needed education and research development in this field.

Other authors have echoed the need for regional approaches, with primary, secondary, and tertiary levels of care based on the needs of patients and families. Primary care will be central to the development of palliative care in Canada. Primary care is and will continue to be provided by family physicians in conjunction with community interdisciplinary teams. Palliative care consultants in their secondary or tertiary roles must develop strong relationships with family practitioners and home care teams because they provide the link between various providers of care.

Clearly, the challenge today is to work within present health care systems and attain the integration and coordination of care necessary to provide the right mix of services in the “most appropriate setting.” More than many other specialties, the palliative care model of care needs to be flexible and to be able to “travel” and meet the unique needs of individuals, particularly in noncancer diagnoses, where most appropriate settings of care will need to integrate with other models of care such as nephrology, pediatrics, and neurology. The ideal setting for palliative care is evidently complex and varies over time.

Provinces generally report that emerging models are using generic services complemented by specialized services. Regions report working with present services, partners, and agencies to bring together the best mix of services possible. Regina Quapelle Health Region has an integrated model in which a care coordinator and interdisciplinary staff follow the client in any setting within the health care region. The Fraser Health
Authority in British Columbia has established a variety of arrangements with community-based hospice groups to establish several residential hospice environments.

For some provinces, such as Ontario, developing an integrated palliative care program in the absence of regionalization requires a unique approach to service delivery. Partnerships between organizations and across settings of care are critical. In Toronto, the Hospice Palliative Care Network was developed to formalize these partnerships. A contractual agreement between the physician group, various service providers, and government was created to address continuum-of-care needs. A computerized patient record is key to the success of the model.

This trend toward partnerships, strategic alliances, shared care models, and contractual arrangements to ensure a continuum of care from acute care to community-based options is seen in the literature. O’Connell\(^5\) completed a comprehensive review of the literature and describes five integrated care delivery models:

1. Shared care: Sharing responsibilities between a specialist and generalist health care professionals
2. Case management/Managed care: An identified person is assigned to a person to manage their care from admission into the hospital to discharge into the community. Often part of a prospective payment system
3. Home care: Person is managed by a team of health care personnel in the community
4. Collaborative practice clinics: Groups of health care personnel who work together in community or outpatient clinic
5. Cancer centers: Incorporate support and coordination of resources, including a directory of local cancer support groups, voluntary organizations, and palliative care

All delivery models should aim to reduce costs and to enhance quality of care, communication, continuity, and patient satisfaction. O’Connell’s review was limited due to the multiple interpretations of each model described, but overall she identified shared care as the preferred model because it has the potential to provide a more continuous and integrated form of care.

Rather than recommend any particular model, Wilson\(^1\) identified four key components of end-of-life services that are essential: (1) universality: a broad range of health care and social support services need to be available to all persons who are near the end of life; (2) care coordination: care should be arranged through an end-of-life care coordinator with specialized knowledge and skills; (3) broad range of basic and advanced end-of-life support: basic services needed by most persons provided by persons who do not specialize in end-of-life care, and advanced end-of-life service needed for a small proportion of persons provided by persons who specialize in end-of-life care; and (4) care regardless of setting: services should not be limited by care setting. Care regardless of setting must be tempered with rural and cultural needs that impact plans for services, such as acute care utilization.

Rachlis\(^10\) poses the following questions as markers of integration and innovation in hospice palliative care service delivery:

- Does your community track the number of deaths in hospitals, hospices, and homes? (If your community has more than 50% of cancer deaths occurring in hospitals, then there are not adequate palliative care services).
- Do your community’s hospitals and nursing homes measure pain as a fifth vital sign?
- Do your community palliative care programs provide care to noncancer persons? These persons should make up more than 25% of the total caseload.
- Are palliative care programs available for the homeless?
- Do your community’s long-term care facilities and home care services complete advance directives on all of their clients?
- What proportion of long-term care facility deaths occur in hospitals? (More than 70% should occur within the facility.)
- Do intensive care units have dedicated staff to counsel persons and their families about preference for care?
- Do ambulance dispatches and paramedics respect advance directives?

**Calgary and Edmonton Model of Care**

Although there is no evidence to date regarding the impact of different models of palliative care on patients’ quality of life, models may be justified on other grounds, such as patient preference or cost effectiveness.\(^3\) There have been individual studies examining aspects of integrated programs such as consultation teams and satisfaction and acute care utilization. However, the ability to research the impact of an integrated model of care is limited because these programs are relatively new and complex to describe, and the research involves linking administrative data sets.

The impact of an integrated regional community-based palliative care program on patterns of care for terminal cancer patients has been studied in the Calgary Health Region and the Capital Health Region (Edmonton), Alberta.\(^2\) The objectives for the study were to describe, explain, and evaluate the economic consequences of introducing two comprehensive, coordinated, and integrated palliative care programs in Alberta. A before-and-after analysis of linked administrative data for cancer patients who died between April 1993 and March 2000 as residents of Calgary or Capital Health regions was completed. Cancer registry, administrative, and palliative care databases were linked, including information on utilization.
and cost of hospital, physician, outpatient prescriptions, and nursing home and home care data.

Shortly after the establishment of the Regional Health Authorities in Alberta, the Capital Health and Calgary Regional palliative care programs (RPCP) were created in July 1995 and October 1996, respectively. At that time, both programs presented convincing business cases for the establishment of a regional program. Regionalization provided a vehicle to develop an integrated service delivery model. The aim in both regions was to increase the access of patients to palliative care services and decrease the number of these patients dying in acute care facilities by enhancing the developing community-based service options. Services include:

- Tertiary or specialized palliative care units for those persons with complex symptoms requiring intensive interdisciplinary support (14 beds in Edmonton, 10-bed tertiary unit began after study period in Calgary)
- Hospices: end-of-life care settings for persons unable to be cared for in their home but who do not require acute care, located either freestanding or in long-term care facilities. Interdisciplinary team, 24-hour registered nursing, dedicated nurse managers, and consultants are provided. Admissions are centrally coordinated and respite care is provided if a bed is available (57 beds in Edmonton, 40 in Calgary at the time of the study).
- Palliative home care: both regions have specialized interdisciplinary home care programs to support persons in their homes. During the study period, significant investment had been made to further enhance the capacity of the home care programs to provide round-the-clock care.
- Consultants: available throughout the regions for any setting providing consultative support to primary care providers in acute care, long-term care, and community settings. Consultants are also responsible for palliative care education to primary caregivers.
- Central office to coordinate administrative, education, research, bereavement, and volunteer activities

Admission criteria for each area of the programs assist in assessing for care options. Common assessment tools are used to evaluate symptoms, cognition, and functional status. Both regions have established strong liaisons with cancer agencies that link patients to the regional palliative care services to enhance seamless care.

The results of the study are:

1. Access to palliative care was defined as referral to any part of the program, which would provide knowledgeable access to all parts of the program. Over the 7 study years, access increased from 45% to 81%. This increased coverage rate was attributed to the increase in hospice beds, consultation, and home care services (Figure 66–2).
2. People were predominantly referred to hospice palliative care services in the last month of life, with 31% of palliative home care admissions and 71% of residential hospice admissions occurring in the last month of life.
3. The percentage of time that palliative clients spend in their home is more descriptive of palliative care services than where people die. In the last study year of 1999/2000, 87% of a person’s time during that year was spent at home, 12% of this while receiving palliative home care near the end of life. Time in institutional care over the year was 6% in tertiary palliative care, 7.5% in acute care,

---

**Figure 66–2.** Probability of referral to palliative care by type of service at any time in last year of life, 1993/1994 to 1999/2000 (n = 16,282). Source: Fainsinger et al. (2003), reference 61.
2.4% in hospice, 3.5% in nursing home. Clearly, the majority of time is spent at home before entering specific palliative care services. The authors have identified that the time prior to entering palliative care services is an area worthy of further study.

4. Actual location of death was 37% acute care, 29% hospice, 28% home, 3% nursing home, and 3% tertiary care in the last study year of 1999/2000.

5. The integrated regional palliative care programs were implemented at no additional cost to the public sector (Figure 66–3). The number of acute care bed days per year used by palliative care persons decreased from 10.4% to 7.5%, representing a savings of 74 acute care beds/year. This has been offset by care provided in less costly settings: palliative home care increased from 7% to 12% and hospice increased from 0% to 3%, which is equivalent to 61 beds in hospice. Tertiary and nursing home and time at home remained constant.

6. Overall acute care accounts for two thirds (67%) of the cost of palliative care services provided in the last year of life, followed by physician services (10%), hospice care (8%), long-term or nursing home care (6%), home care (6%), and outpatient prescription medications (see Figure 66–3).

7. Age (older), gender (female), socioeconomic status (lower income), cancer diagnosis (breast, respiratory, buccal), and disease burden (multiple comorbidities) can significantly explain increased use of hospital and physician costs.

A community-based integrated model of palliative care service can be implemented to increase access at no additional cost to the health care system in large urban settings.

**Conclusion**

The Senate Subcommittee, updating the 1995 special Senate report on euthanasia and assisted suicide, called their report _Quality End-of-Life: The Right of Every Canadian_. The name of this report sets the stage for public expectation for hospice palliative care services. The aging population and the prominence of the Prime Minister with Special Responsibility for Palliative Care supports the expectation of quality end-of-life care for all Canadians.

There are many components in place to enhance model development of palliative care services in Canada. The recent reports on health care, with clear expectations of palliative care services in home care, have advanced a clear rationale for universal access to competent, effective palliative care that can address the rural and cultural challenges. The national standards of hospice palliative care should guide those developing and enhancing palliative care services as we move toward national accreditation standards. Certification of palliative care for physicians and nurses is an important step in increasing the availability of palliative care within the health care structure.

Palliative care is well positioned to succeed in a community-based model of care. The call for adequate resources in these programs of care must be heeded to ensure that palliative care is widely accessible.

PALLIATIVE CARE IN AUSTRALIA AND NEW ZEALAND

Sanchia Aranda and Linda J. Kristjanson

... this source of hope—that our last moments will be guided not by the bioengineers, but by those who know who we are . . .

Palliative care nursing in Australia and New Zealand shares many features of palliative care nursing as practiced elsewhere in the world. The similarities between Australasian palliative care nursing and palliative care nursing in other countries is evident in the Australasian contribution to journals such as the International Journal of Palliative Nursing and in the adoption of Australian palliative nursing texts by international publishers. The purpose of this chapter is to both profile palliative care in Australia and New Zealand and to provide insights into some of the key innovations in care where nurses are providing a leading role.

In developing this second edition, we have retained and updated those sections of the chapter that provide an overview of palliative care in Australia and New Zealand. This material was gained from practicing nurses in Australia and New Zealand for the first edition and has been largely updated here from website sources and published materials. In this edition, we have shifted our specific focus to the imperative to increase access to palliative care across the population. More specifically, nurses have taken a leading role in innovations featured here such as the development of models of care for noncancer populations and in provision of after-hours support. The chapter concludes with a brief look at the steps Australian palliative care nurses are taking towards advanced practice roles.
Some Essential Differences Between Australia and New Zealand

Australia and New Zealand are often considered together—consistently labeled as “down under” and far away in world consciousness. Despite being close geographically and sharing a predominantly British heritage, these countries have significantly different personalities that are important to understand before exploring palliative care developments of the two countries.

New Zealand is a small country consisting of two large islands and one smaller, sparsely populated island. The total population is 3.7 million according to the 2001 census and is estimated to be 4 million in 2004 based on previous population growth. The population is unevenly spread between the two main islands, with almost 75% living on the North Island. European/Pakeha (white) make up almost 80% of the population, plus 14.5% Maori and 5.6% Pacific Islanders. The economy is predominantly agricultural. Specialist health services are likely to be confined to large cities in each of the two main islands, but most general health services are available locally. However, New Zealand’s population density, 12.6 people per km² compared to 234.5 per km² in Britain, has some effect on access to health services, with those in less densely populated areas having less access to specialized services, including palliative care.

In contrast, Australia is a large island continent of five states and two territories plus Tasmania, a small island state to the south of the main island. The population is approximately 20 million. According to the 2001 census (http://www.abs.gov.au), indigenous Australians make up only 2.2% of the population, although the total number of 410,003 individuals was up 16% since 1996. Australia has undergone significantly more migration than New Zealand, with 22% of the population born overseas at the 2001 census. Overseas-born Australians are predominantly from the United Kingdom and Ireland, making up 5.5% of the total population. A further 1.9% of the population was born in New Zealand, and 1.2% in Italy. However, migrants from a variety of Asian countries make up a further 4.9% of the total population, or 982,519 individuals. To illustrate the diversity, Melbourne was recently declared the world’s most ethnically diverse city, with residents from more than 140 countries (http://www.melbourne.vic.gov.au).

Australia ranges from dense urban cities such as Sydney, with approximately 4 million people, through rural communities surrounding large towns, to isolated remote areas where the nearest neighbor may be a day’s drive away. Although the Aboriginal population constitutes only 2.1% of the population, they make up 30% of the population of central Australia, and in some communities are the primary clients of health services.

It is clear, then, that Australia and New Zealand have similarities and differences. Both countries feature a predominance of people from Anglo-Celtic origins and were populated by these settlers at a similar time, although under different circumstances—Australia was established as a penal colony and New Zealand with free settlers. Both were colonialist settlements featuring disenfranchisement of the existing population—in Australia, the native Aboriginal people, and in New Zealand, the Maori. Since that time, New Zealand has remained largely bicultural despite limited migration from other parts of the world, while Australia is considered a multicultural society. Despite the diversity of languages spoken in Australia, English is the only official language. In contrast, both English and Maori are recognized national languages in New Zealand, and significant effort has been made to maintain Maori cultural identity and influence at a national level. Resurgence in Maori nationalism over recent years has been more effective in influencing national policy than has similar indigenous nationalism in Australia.

Australian and New Zealand Models of Health and Palliative Care

Both countries have a long history of universal health insurance systems that provide basic health care to all people. This universal health care system is supplemented by a limited system of private health care, more extensive in the Australian context. There is a consistent valuing of universal access to adequate health care within the two populations despite increasing trends toward user payment for some services. User payments are more common in New Zealand, where services such as visits to the local doctor are user pay, but user copayments are increasingly common in Australia.

Both countries feature a trend toward privatization of public facilities that affects health care services, perhaps most noticeable in care of the aged. Privatization of nursing home facilities has resulted in an increased need to profit from care of the elderly, with considerable potential impact on access to palliative care services when combined with the shift toward user payments. Health care is of a high standard, with access to a range of generalist and specialist services at a level consistent with that of the United States and Europe. Most generalist services are available in rural communities, but specialist services such as radiotherapy usually require travel to a large city. In remote areas of Australia, access to health care may be limited to a regular monthly clinic by the Royal Flying Doctor Service and limited access to outreach telephone services. In some remote settings, nursing care may be provided through remote nursing stations, where nurses are expected to serve as advanced generalists attending to a range of health care concerns within the community.

Structure and Delivery of Palliative Care

Hospice and palliative care developments in Australia and New Zealand are well advanced, with services required to meet established standards of service delivery. Models of palliative care delivery in these countries feature inpatient, home care, and hospital support teams, with New Zealand evidencing more use of palliative day care than Australia. Urban cities tend to feature all service elements, with home care provision showing the most variation. In larger rural cities, small specialist
services provide support and consultancy services to generalist nurses and local doctors. Palliative care developments in both countries are notable for their lack of homogeneity, with models of care dependent on historical factors, financial support, population density, and the local community environment.

The first hospice service in New Zealand opened in 1979, and there are now 37 services operating across the country (http://www.hospice.org.nz). Palliative care in New Zealand features the development of small community inpatient hospices that link strongly with local community nursing services in the provision of home care. The system is well organized through Hospice New Zealand, which facilitates communication between members and organizes the national conference (http://www.hospice.org.nz).

The first Australian hospices predate the opening of St. Christopher’s in London (1969) by 79 years—the establishment by the Sisters of Charity of hospices in Sydney (1890) and Melbourne (1938). Following the global spread of modern hospice, Australia’s response occurred largely through the development of community-based palliative care services, with a particular emphasis on care in the home. However, significant change is occurring in the provision of home care. The system is well organized through Hospice New Zealand, which facilitates communication between members and organizes the national conference (http://www.hospice.org.nz).

Palliative care services in both countries ascribe to the principle of supporting the patient’s decision to die at home whenever possible. Australian government policy directions clearly support the care of people in their own homes. This emphasis includes specific attention to respite care and 24-hour access to supportive advice. Of people receiving palliative care in Australia, approximately one third die at home. Average length of stay on a home care service is approximately 102 days, and average length of stay for patients receiving inpatient palliative care is 12 days. However, these figures relate only to those individuals who access specialized palliative care services. Access, including issues such as provision of after-hours care, respite services, and the spread of palliative care into areas such as aged care, is an increasing critical focus of service development efforts. In the remainder of this section, we will focus on five areas relating to access to palliative care: provision of culturally sensitive care, access in rural and remote communities, services for noncancer populations, provision of after-hours support including respite, and access to palliative care in the aged-care sector.

Cultural Issues

A key feature of New Zealand health care is its responsiveness to Maori nationalism, which calls for greater control over their own health and services compatible to cultural beliefs. Cultural safety is a feature of Maori demands for appropriate health service development, and is a concept that moves beyond cultural sensitivity, featuring both acknowledgment and respect for difference, toward implementation of strategies to promote and nurture the cultural identity of the person who is ill. In New Zealand, nurses have taken the lead on cultural issues in health with the production of guidelines in 1992, which were updated in 2002. These guidelines define cultural safety as “an outcome of nursing and midwifery education that enables safe service to be defined by those who receive the service” (p.8). Ultimately this means that people of one culture feel able to use a health service provided by another culture without feeling at risk. The New Zealand Palliative Care Strategy, released in February 2001, specifically details expectations for Maori and Pacific people, including development of linkages with Maori organizations, local service plans, and the employment of care coordinators in conjunction with local Maori providers.

In contrast, the Australian indigenous people remain a marginalized group, with a health status significantly below that of other Australians despite strong government programs to address indigenous issues. A long history of neglect and suffering as a result of earlier ethnocentric government policy has left a legacy of difficulties for indigenous Australians. The provision of sensitive care to dying Aboriginal and Torres Strait Islander people is beginning to feature in national consciousness, and some research in this area is emerging. The 2003 Australian palliative care conference illustrated the emerging emphasis on access to palliative care for indigenous Australians, with three conference sessions devoted to this topic with a range of indigenous and health professional speakers. Current models of palliative care delivery, with an emphasis on terminal illness, may be unsuitable for some indigenous Australians whose concept of life-death-life may not be well understood or catered for in the traditional palliative care approach.

The National Palliative Care Strategy identified the need for services “... to cater sensitively and flexibly for the needs of Aboriginal and Torres Strait Islanders” (p.6), but did not identify specific goals or strategies, and key indigenous groups are not listed among those consulted in developing the document. More recently, Palliative Care Australia released the second edition of the Australian Service Planning Guide for palliative care, which does not specifically address the needs of indigenous Australians or consult with key indigenous groups. However, significant government resources are being channeled into developing models for indigenous palliative care. A comprehensive needs study was commissioned by the Australian government outlining a blueprint for service development. Importantly, this report recognizes the key differences in service expectations, articulates a critical role for Aboriginal health workers, and addresses the significant training and education needs of health service providers. Further work is being undertaken to develop guidelines for culturally appropriate palliative care service delivery.

In a recent summary of the issues in indigenous palliative care, Dr. Olra Fried demanded that services hear from indigenous Australians about what quality of life means as a way of considering how services might best be provided. She further suggested that indigenous people and mainstream service providers have differing world views, conflicting values, different
ways of making important decisions, and problems with communication (both verbal and nonverbal), and that recognition of these is essential in service planning. Drawing on research work to date in Australia, Fried identified that many indigenous people “. . . feel alienated from and distrust mainstream services . . . , want to be cared for and die on their traditional country . . . ” and “there are inadequate resources to support home palliative care . . . ” on traditional country (p. 4). Fried’s recommendations for moving forward on indigenous palliative care are to:

- Focus locally in service development.
- Develop local support and information networks.
- Provide training in palliative care for Aboriginal health workers and bereavement workers.
- Provide cross cultural training in indigenous care for non-Aboriginal workers.
- Gain Aboriginal input into service planning, development, and management.
- Make specific efforts to facilitate Aboriginal access to mainstream services.
- Maintain access to traditional healers and bush medicines for Aboriginal people receiving palliative care.

Models of care, such as the employment of an Aboriginal social worker at the Mount Isa Hospital in remote Australia offer some hope for service improvements.19 Burns’ role as a Palliative Care Aboriginal Liaison Officer helps to bridge communication between her people and mainstream services.

The large number of migrant Australians, for whom English is not a first language and cultural beliefs about death and dying differ from Western belief, creates different demands on palliative care services. The provision of palliative care for these groups is beginning to feature in national research and service delivery efforts,20–24 with nurses often leading the call for improved service provision to people of non-English–speaking backgrounds.25 Importantly, Kanitsaki’s research has challenged a dominant palliative nursing belief in open discussion about death and dying. Participants in her studies of Italian, Chinese, and Greek Australians often perceived nurses “who attempted to discuss with them death and dying” as “negative, insensitive and transmitted to them a sense of hopelessness” (p. 39). In addition, nurses who were accepting of death and told participants they were dying were interpreted as giving up on them, producing fears that the nurses would stop caring.

Access to information about palliative care is now available in 21 languages through the website of Palliative Care Australia (http://www.pallcar.org.au); however, attempts to improve information access are just a beginning. Systematic attention to cultural safety should move beyond access to interpreters, multilingual information, and liaison with ethnic community organizations and religious groups.9

Improving Services for Noncancer Populations

Three projects developed from a recent National Health and Medical Research funding scheme in palliative care specifically address noncancer palliative care in the areas of heart failure, renal disease, and neurodegenerative disorders. The project in neurodegenerative disorders was developed by a national team of nurse researchers and offers some useful insights into the issues associated with palliative care for non-cancer populations.

Individuals living with neurological diseases such as motor neuron disease (MND), multiple sclerosis (MS), Huntington’s disease (HD) and Parkinson’s disease (PD) face long-term physical and psychosocial challenges. These are all progressive diseases primarily occurring in adulthood and all are incurable. The illness trajectory for these people may be long (years or decades) and involve lengthy periods of dependency. A range of technologies and health care options may be used to ensure adequate nutrition, communication, cardiac and respiratory functioning, bowel motility, and skin integrity. All of these initiatives require learning and adjustment on the part of the individual and family. The psychological and social factors of managing living with a neurodegenerative disease are as important as physical care. Healthy recovery of family members after their eventual bereavement is also essential.

Neurodegenerative diseases have the capacity to evoke the most negative and despondent attitudes in the minds of many health care professionals. These attitudes may readily transmit to patients and their families.26 The fact that we cannot significantly alter disease progression is sometimes interpreted to mean that there is nothing more to be done.27 This is inaccurate and regrettable. It is precisely because we cannot reverse or even retard the disease process that everything possible must be done to alleviate symptoms and offer appropriate psychological and spiritual support. This is where a palliative approach has much to offer.

Although many of the neurodegenerative disorders are relatively rare, the symptoms that occur in association with these disorders are quite common. Symptoms such as pain, breathlessness, constipation, and insomnia are commonly encountered, and their routine management should fall within the scope of all competent practitioners.28 Of course, more complex issues such as nutritional support using enteral feeding, respiratory function with a view to ventilator support, or management of neuropathic pain may require consultation.3

A team of palliative care nurses is leading a study to examine the needs of these groups of patients and their families with the aim of identifying approaches to care that may be helpful in meeting the unique needs of these populations. Results from qualitative interviews with 135 patients, family members, and key health professionals from these four disease groups revealed six common concerns: challenges of adjusting to the impact of the illness, surviving the search for essential information, gathering practical supports from many sources, bolstering the spirit, choreographing individual care, and fearing the future. Results indicate that patients and family members needing palliative support also require access to rehabilitative services, genetic counseling, and financial assistance to help them cope with the long-term needs. The role of the palliative care nurse in working with these groups of patients
requires expertise in management of these unique disease symptoms, advanced skills in family counseling, and strong interpersonal skills to help patients and families navigate the rehabilitation–palliative care pathway.

Rural and Remote Communities

Nurses working in rural areas believe there is significant work needed to provide for the palliative needs of rural communities. Rural and remote communities are not homogeneous; they offer various challenges to health delivery based on demographics, local culture, physical environment, and distance from health services. Rural nurses, providing palliative care as one aspect of a broader health role in the community, suffer significant professional isolation. In some settings, particularly in remote areas, the nurse may be the sole health practitioner in a community, receiving telephone support from a doctor located some distance away. The challenge is to develop sustainable models of palliative care provision in many of these communities.

The provision of palliative care to people in rural areas is a major component of government attempts to improve access to palliative care. In many rural communities, a specialist palliative nurse consultant has been employed to work with a local team of interested people to provide palliative care support to local health services. Many rural local doctors have taken up the challenge to improve their palliative care skills and work in partnership with the nurse. There is now evidence that these approaches are working.

Sach undertook a major study to explore the provision of rural palliative care in Australia. This study found the role of palliative nurse consultants to be vital in the provision of quality palliative care in rural areas. The rural palliative care nurse was identified as maintaining an up-to-date knowledge of treatments and drugs that was vital for their support of local doctors. The consultative nursing role was appreciated as being in the background, supporting the family and community nurses to provide care. Despite the fact that rural palliative care services staff were likely to visit less often than city services staff, there was greater use of telephone support and community members, and innovative use of nursing support through access to specific funds available for rural health. Overall, the study found rural communities to not be disadvantaged in the quality of palliative care provided.

Since this report, a number of innovative projects have commenced that seek to redress service access issues in rural and remote communities. For example, a collaborative project between doctors and nurses in South Australia uses video phones to link specialist palliative care outreach nurses with local health services caring for patients with palliative care needs. This project, while still under evaluation, enables remote clinicians to participate in multidisciplinary clinics and improves cross sector communication.

A second innovative and nurse-led project aims to implement a "Palliative Care Toolkit" that provides local community health providers with a framework for activating palliative care services when required. This framework assists the local community to work together, drawing on the existing community and health care resources to establish as-needed palliative care services. This "pop-up" model of service provision recognizes that rural and remote communities have a small number of people requiring palliative care services annually and thus require a service provision model that can be activated on demand. The toolkit is being tested in rural and remote sites in three states of Australia (Professor Kate White, personal communication, 2004). The key principles that underpin this project are sustainability, being community led, and responsiveness, and they illustrate how palliative care nurses are taking a leadership role in innovative service delivery based on the unique needs of local communities.

Models of After-Hours Service Provision

A dominant feature of Australian community palliative care service provision is 24-hour access to support. The nature of this support differs across services and between rural and metropolitan areas, and maintaining the after-hours service can place significant strain on small services and terms of small numbers of nurses sharing after-hours responsibilities. Two models of metropolitan after-hours provision have developed that address this strain. The first consists of a triage model where a related inpatient service receives calls from patients or family members at home regarding their needs. In an evaluation of this model, the triage nurse was able to manage 30% (192 calls) of calls alone. The remaining 70% (437 calls) were transferred to the specialist community palliative care nurse on call. Of these, a further 43% (186 calls) were managed by the specialist nurse with telephone support. The remaining 57% (251 calls) required a home visit. Importantly, the availability of the triage nurse was significantly related to whether the call could be managed alone, suggesting improvements in training and support for the triage nurse could increase the number of calls managed in this way and further reduce burden on the specialist community palliative care nurse.

The second model consists of sharing after-hours responsibilities between specialist palliative care services and generalist community nursing services. Across Australian metropolitan areas, generalist community nursing services already offer after-hours care and are already available to visit palliative patients at home. All of these nurses are provided with basic palliative care knowledge and skills and have access to updated information about the specific palliative patients seeking after-hours support on a daily basis. In some settings, this service is supplemented by telephone support after hours by a specialist palliative care nurse, increasing the capacity of the general community nurse to meet the patients’ needs.

Night respite can be another means of improving after-hours support. A recent Australian study undertaken by Kristjanson and colleagues described the benefits of night respite for patients receiving a home palliative care service and their families. The investigators developed and tested a brief assessment tool to determine those patients and families most in need of night respite. Care aides were then specifically trained to
provide night respite support, and 53 patients received this support over an 11-month period. Results indicated that the assessment tool was reliable and feasible for use in practice. Findings from this study revealed the types of patients most in need of night respite support were confused, agitated, or incontinent. As well, families with high levels of caretaker fatigue were particularly in need of this type of respite. Patients and family caretakers reported high levels of satisfaction with the night respite service, and 70% of patients who died during the study were able to die at home. Cost estimates indicated that the home care and service, and ers reported high levels of satisfaction with the night respite service. As this study revealed the types of patients most in need of night respite support were confused, agitated, or incontinent. The palliative approach aims to improve the quality of life for individuals with a life-limiting illness and their families by reducing their suffering through early identification, assessing and treating pain, and addressing physical, cultural, psychological, social, and spiritual needs. The palliative approach should be able to be provided by all health professionals in all settings of care, with referral to specialist palliative care services where patient needs require this.

In response to this need, in 2002, the Australian Government Department of Health and Ageing commissioned the Australian Palliative Residential Aged Care (APRAC) Project Team to develop palliative care guidelines for the residential aged care setting (http://www.apracproject.org). The interdisciplinary team was led by nurses in palliative care and aged care and includes individuals with special expertise in guideline development, dementia, and cultural issues.

The aim and scope of the guidelines is to identify evidence-based recommendations to inform a palliative approach in residential aged care facilities. The guidelines are not intended to be rigid, prescriptive pathways, for it is the needs of the individual that determine the care one receives. The guidelines prompt creative solutions appropriate to diverse settings, varied resident needs, and unique workforce characteristics of the many residential aged care facilities that exist across the country. The guidelines provide staff working in these facilities with evidence-based criteria against which their services can be monitored. The guidelines will also assist in the identification of local strengths and weaknesses in the provision of a palliative approach in residential aged care facilities, providing a mechanism by which changes in service delivery may be evaluated over time.

Advanced Practice

Advanced practice role development in Australia is in its infancy, with state nurses’ boards just beginning to set frameworks for nurse practitioner endorsement. New South Wales is the most advanced in terms of nurse practitioner developments, with South Australia and Victoria having received applications for endorsement of nurse practitioners in palliative care. Karen Glaetzer became Australia’s first community palliative care nurse practitioner (NP) in August 2003, the third NP in that state. Glaetzer works at the Southern Adelaide Palliative Care Service in a combined role as NP and Outreach Coordinator, with the future plan to become a full time NP. Glaetzer’s role as an NP involves case management of patients identified to have complex needs, with a particular emphasis on those with difficult family/social issues, young patients with dependent children, significant mental health concerns, or serious comorbidities. To achieve endorsement, Glaetzer was required to present a portfolio addressing 10 standards set by the South Australian nurses board, including the development of relevant practice guidelines. The endorsement process also involved an interview and presentation to the board about the clinical preparation undertaken for role performance and discussion of role expectations. While there is no minimum education requirement for NP endorsement, there is an expectation that NPs will have master’s degrees. Prescribing preparation has been included in NP preparation, but in South Australia, government processes to allow nurse prescribing are incomplete. For the first 5 years, Glaetzer is required to provide evidence annually of her continued maintenance of the standards (Karen Glaetzer, personal communication, April 2004). Details about the process for endorsement can be found on the following website: http://www.nursesboard.sa.gov.au. In Victoria, four community palliative care nurses have been involved in a pilot role development program over 2003 and are in the final stages of seeking endorsement. Details on the Victorian nurse practitioner projects can be obtained from the following website: http://www.nbv.org.au.

Conclusion

Palliative nursing in Australia and New Zealand continues to develop and grow. Since the first edition of this book, the leadership role of palliative care nurses in advancing the development of palliative care has become increasingly evident in practice, education, and research. This development is supported by new academic positions in palliative nursing in several states, and individuals employed in these positions are attracting research funding from state and national competitive research funding bodies. The hallmark of these academic positions is their close relationship with clinical facilities, helping to ensure that the research agenda for palliative nursing is firmly grounded in important clinical issues. As demonstrated by the work profiled in this chapter, nurses are at the forefront of developing a service system able to meet the needs of marginalized groups in our communities and are committed to sustainable models of palliative care delivery. Palliative nurses, like nurses everywhere, are being asked to demonstrate their contribution to the health and outcomes of palliative care.
clients. We believe the important integration of research and practice developing in the Australasian context will allow palliative care nurses in Australasia to take a leadership role in advancing palliative care practice knowledge internationally.

PALLIATIVE CARE IN THE UNITED KINGDOM

Andrew Knight

It is now 38 years since St. Christopher’s Hospice in Sydenham, a suburb of South East London, opened its doors to patients. St. Christopher’s had been long in gestation. Cicely Saunders had been thinking about, praying for, traveling (in effect, what we would call “networking”), and generally organizing her hospice for the previous 20 years. The amount of organizational effort that Saunders and her supporters put into the project that she called her “spiritual odyssey” meant that it could not fail, yet they were never sure it would wholly succeed. The building
itself, a large concrete and glass structure and architecturally very much of its time, proclaims a bold statement that few could ignore. Here was something new, something that would not go away.

Yet Cicely Saunders and those early pioneers did not imagine that the concept of hospice—a philosophy of care that would encompass all needs of the terminally ill patient and their family—would lead to a movement replicated around the world in hundreds of settings and cultures, and to a new form of medicine that would change forever how systems of care are delivered: palliative care.

Students of the origins of hospice are indebted to the ongoing careful work of Professor David Clark. He makes the important point "that to claim an arbitrary starting point for such a complex and far-reaching movement is unsatisfactory. Indeed it may be preferable to see the opening of St. Christopher’s in 1967 as a crucial outcome of ideas and strategies . . . in which can be located the essential characteristics of the subsequent hospice movement." Many of the principles of hospice care are as sound and applicable now as they were then.

Cicely Saunders’s sense of a calling to undertake this work and the idea of a religious community operating outside the mainstream of the health service is prevalent throughout the decade prior to the opening of St. Christopher’s. It is now interesting to speculate what would have happened had she not decided, in a pragmatic way, to embrace the need to work practically within the world of modern medicine and social services. Would the movement have had so much influence? Certainly in the 1960s there was a greater openness to question the norm, to challenge tradition; and the public was beginning to become interested in alternative therapies, such as Eastern and homeopathic medicine. But would politicians, administrators, and planners of health care have been so influenced by an evangelical religious community? This is not known. However, it is clear that the originators of St. Christopher’s and those that followed in its wake were religiously motivated; they carried with them a religious zeal to change the way that society and, in particular, the medical establishment cared for the dying.

Would St. Christopher’s have been established if it were to be proposed now, at the start of a new millennium? Many of the advisors to Cicely Saunders were religious and established figures in the church. The church in a largely secular Great Britain has much less influence and power than it did in the 1950s and early 1960s. The concept of hospice care remains hugely popular with the public, who identify with its philosophy and approach to care. Moreover, it is thought to be an essential component of the modern health care system in the United Kingdom, one that should be replicated elsewhere. Many public figures sit on hospice boards of trustees, giving voluntarily of their time. However, it is not at all clear in a modern world, where health budgets are being cut and stretched to deal with pressing needs, that another seat at the table labeled “palliative care” would be at all welcomed.

Influence of Cicely Saunders and St. Christopher’s Hospice on Nursing

From the beginning, the need to publish and to spread the new principles of the care of the dying was recognized. Cicely Saunders had an article on euthanasia published in October 1959 in Britain’s most widely read nursing journal, Nursing Times. This was the first of a seminal series of six articles, whose influence has been immeasurable, on the care of the dying. They contain advice on “should a patient know?”; pain control; mental distress in the dying; and principles of and the nursing care of the dying. It is not surprising that they can still be purchased in reprint form today, as they contain many of the founding principles of palliative care. Many nurses came to know about hospice through reading these articles.

The Joint Board of Nursing Studies (later to be divided into four national boards) was formed to oversee the burgeoning number of postgraduate courses for nurses in the United Kingdom. It recognized the need to formulate a course in the “Care of the Dying Patient and their Family” in 1974—the first course appropriately being run at St. Christopher’s. This course, now run by a number of colleges of nursing remains as popular as ever, containing as it does a synthesis of the subject. Known popularly as ENB 931 after its old catalogue number, it remains the touchstone course for any potential applicant to the specialty.

The impact that this new approach had on nursing throughout British hospital nursing care was considerable. The rise of a movement in the United Kingdom and the growth of hospice facilities was fired by inspired nurses wanting to practice this form of care who were frustrated by the lack of resources in the National Health Service. It was mirrored by a growing sense of professionalism in nursing and the need to formulate philosophies of care. Virginia Henderson’s model seemed to many to come closest to an ideal model of care and was readily taken up by the influential Royal Marsden Hospital, the United Kingdom’s premier cancer hospital. However, it was not until the 1980s that a full model of care, embracing palliative and cancer care, came into being, when the Royal Marsden Hospital added palliative care to its curriculum in 1986.

The acquired immunodeficiency syndrome (AIDS) pandemic in the mid-1980s took many by surprise and challenged those who were equipped and trained to deliver palliative and cancer care to this largely dying population. The providers of mainstream hospice care were, with some notable exceptions, seen to be indifferent, fearing the difficulties of an unpredictable human immunodeficiency virus (HIV) trajectory and the effects on a largely voluntary income. Criticisms of homophobia were not unjustified. Two hospices specifically for the care of the HIV patient were formed: the London Lighthouse in North West London, and the resurrected Mildmay Mission Hospital in East London. These remain, but the focus, at least for the time being, have shifted from providing inpatient care to that of education, counseling support, and outreach work. The self-determination and questioning spirit of the HIV
patient was a good foil to an apparently unquestioning elderly cancer patient. Nurses working with this group of patients learned a great deal about the care of a group of patients who questioned the status quo—lessons that have been included in palliative nursing courses.

**Hospice Care Under the National Health Service**

The National Health Service (NHS), promising free health care for all, was 19 years young in 1967 and still considered successful. Its modes of operation were well established and took up much of the resources and time. There was largely indifference to care of the dying. Systems of nursing, based on the traditional work-based apprentice model, were designed so that each block of extensive work practice was preceded by a (hopefully) appropriate block of classroom teaching. The Committee on Senior Nursing Staff Structure, known universally as the Salmon Report, refashioning nursing management and crucially introducing a tier of nursing officers that were to stay in nursing for 30 years, had yet to take effect. Matrons and assistant matrons still ruled in a world where little audit of care or questioning of practice took place. The first degree program in nursing, at Manchester University, would not appear until 1969.

The first hospices emerged into this system. Independent in nature, they relied on charitable giving and voluntary labor, raising funds to provide for capital building and staffing. At the same time, they looked to the health service, in the form of hospital boards and regional health authorities, for contractual arrangements for patients. Some, such as St. Christopher's, also received grants from the Ministry of Health for pain research.

The emotional appeal of terminal care was strong. Its zealous founders were convincing in their moral arguments that society address the need to care for the dying, who were languishing without adequate pain control in hospitals. It easily captured the public’s imagination, as all families would experience death; in particular, the way that the dying were cared for, good and bad, had special meaning. Catching health care planners off-guard, the spread of hospice facilities was rapid and ad hoc. Indeed, the need for hospice care and the question about the use of resources allocated to it were not carefully examined until the advent of the so-called purchaser-provider split as part of the conservative government health reforms of the 1980s. To question the motivation of benefactors providing for worthy services was thought incorrect, to say the least. Although clearly the hospice movement could not exist outside, with its charitable foundations it was difficult for it to survive unchecked inside the NHS. Perhaps reluctantly, they were mutually dependent, and for hospices to survive, some growth regulation and some organizational sense had to be brought to bear. This was gradually taken up by regional, area, and local health authorities. A sense of need for hospice facilities was sought.

In 1980, the Working Group on Terminal Care produced the first report on the provision on hospice serves. Believing that a lack of specialist staff and financial resources would limit the growth of independent hospice facilities, it recommended concentrating on home care (care of the terminally ill in their own home) and day care. Fundamentally, its members held the view that the dying should not be “hidden away” from the provision of wider, hospital and community-based services. However, the Working Group’s prediction that the number of stand-alone services would be self-limiting was found to be false: the number of such units trebled in the next decade. This also ran contrary to the recommendation of a survey by Lunt and Hillier, who, in the following year, recommended that inpatient services be limited and that community services be coordinated to ensure equity of access across regions.

In 1987, 20 years after the first “modern” hospice started treating patients, the Department of Health set out its stall. In the first official circular on the subject, it firmly recommended that district health authorities gauge the need for and control the provision of hospice services. It underscored the need to control hospice finances to ensure that facilities were financially secure to meet all contingencies, such as nurse salaries.

In 1990, in what was quickly to become a controversial departmental press release, the government seemed to be prepared to commit “a pound for a pound” of charitable giving. This announcement was indeed followed by a large injection of some £8 million and an unequal and divisive scramble among hospices and NHS providers of palliative care for funds. It seemed to say that monies for this health sector were limitless and, in turn, led to much ill feeling among other, apparently equally deserving, providers of health care. Deeply unpopular except among hospice providers, the scheme was dropped in 1995, and the age of earmarked monies for palliative care was over.

The 1980s had seen the beginning of health care reforms that continue to this day. Believing that the NHS was bureaucratically badly managed by ill-equipped managers who could not compete with the vested self-interests of its professionals, the conservative government finally introduced a system of general management in 1983. Writing in the report that was to carry his name, Sir Roy Griffiths, the head of a supermarket chain, famously declared that “if Florence Nightingale were carrying her lamp through the corridors of the NHS today, she would almost certainly be searching for the people in charge.” It was felt by commentators that with the introduction of “general management” and its business ethos, professional and clinical staff had lost out. Certainly a paradigm shift in power had taken place.

Fundamentally for the provision of hospice care, these management reforms ensured that there was now a clear demarcation between the purchasers of care, the district health authorities, and the newly formed General Practitioner fund holders, and its providers, independent hospices and charitable providers of funds, notably Macmillan Cancer Relief. Crucially, purchasers brought to bear four key components to the
planning of palliative care services: an overall strategy; a service specification (of assessed need); the contracting process to allocate funds; and the need for clinical audit and quality assurance. The multidisciplinary Standing Medical Advisory and Standard Nursing Advisory and Midwifery Committees (SMAC/SNAMC), reporting in 1992, again recommended that palliative care should not be concentrated in hospice units, and that need should be assessed demographically and care delivered as an integral part of the local health service. This far-reaching report served as a blueprint for purchasers and providers alike, and by 1995, 97% of hospices had entered into a contracting relationship with health authorities.

“The idea that health care services should be predicated upon a rational assessment of need rather than upon emotional pleading, political lobbying, or the vested interests of particular providers is one with which it is difficult to disagree.” The palliative care community was enthused at the opportunity to state the needs of their population group and lobby for a properly financed commitment based on that need. However, it became clear that the needs of the cancer patient and their families are many and include needs previously not considered by cash-strapped health authorities: psychosocial, social, and emotional. The strategy developed into one of prioritizing need and hoping that the limited resources would be shared equitably.

The remaining years of the conservative governments saw the conclusion of their health care reforms. The number of general practitioner (GP) fund-holders expanded, and from 1994 were enabled to purchase palliative care services.

GP fund-holding was abandoned with a change of government in May 1997. It has been replaced by, first, Primary Care Groups, and since 2000, Primary Care Trusts (PCTs), who essentially have a not dissimilar role to assess, plan, and commission a local health strategy.

In 1995, the Expert Advisory Group on Cancer published its findings on the provision of cancer services in the United Kingdom. Known universally as the Calman-Hine Report, it found a significant inequality of services—an absence in some areas, a plenitude in others. It recommended a three-tier system of primary care provision, for prevention and initial consultation; cancer units at district level for the treatment of common cancers; and cancer centers to deal with rarer cancers, covering larger populations. It highlighted that palliative care should be a seamless service across all three tiers, effectively underlining the fundamental need for palliative care from diagnosis of cancer. To enable this, teams of palliative care nurses and consultants should work in cancer units and centers.

The Calman-Hine Report did much to raise the profile of cancer within the NHS, and changed the landscape of palliative care forever. It underscored its link with the provision of cancer services at a time when some were beginning to question the need for palliative care to be available for the “non-malignant” population. However, palliative care was established in a mainstream area of health care and one that would assume major importance for the Department of Health. A key policy in commissioning palliative care and one that developed from the work on the Calman-Hine report was the Cancer Plan. The providers of palliative care had to learn how to promote their services; they had to learn a business culture. “At the dawn of the Conservative reforms of the 1990s the position was crystallized completely: join the contract culture or be condemned to obscurity. The independent hospices, after the briefest of vacillations, climbed on board and rarely looked back.”

The latest guidance for the specialty is that of the National Health Services’ National Institute of Clinical Excellence (NICE). This Institute, a government organization for health improvement, has undertaken extensive consultation on guidance for the provision of palliative and supportive care in the United Kingdom. Their binding guidelines recommend explicit service models to the providers of cancer and palliative care services on all aspects their services undertake.

The National Council for Hospice and Specialist Palliative Care Services (NCHSPCS)

Formed in 1991 as a representative and coordinating body for the hospice movement in England, Wales, and Scotland, the NCHSPCS has done much to ensure that hospices have been faithfully represented at every level. Its membership comes from national cancer charities, professional organizations, and regional representatives. Through its professionals’ working parties and guidelines, it has been instrumental in affecting the practice of palliative care. Examples of this work include guidelines on ethical issues affecting palliative care, such as artificial hydration, cardiopulmonary resuscitation, and much on-going work on euthanasia. Other issues covered are guidelines for the management of the last days of life and the use of complementary therapies. Quality guidelines include the use of outcome measures in palliative care. Its work with purchasers of palliative care, ensuring that a high profile is maintained, include guidelines on contracting; needs assessment and research in palliative care; and a statement of definitions of palliative care. A full list of their publications may be obtained by visiting their website.
Hospice Governance

Hospice and clinical governance is another subject on which the NCHSPCS took an early lead. It helped to define the components of appropriate governance and an action plan for its introduction. It has become an established part of the way that palliative care services now manage their staff, clients, and resources; set programs to monitor and receive information on quality issues, clinical audit and evidence-based practice; and work with commissioners and assess risk management. Importantly, hospice governance systems have neatly embraced the need to bring voluntary trustees of services and staff together in a common goal. These systems have been incorporated into standard frameworks for hospices, the most notable being the accreditation program produced by the Health Quality Service, an independent charity that surveys NHS, independent hospitals and hospices, nursing homes, and clinics in the United Kingdom and mainland Europe.

Settings of Care

An important piece of work undertaken by the NCHSPCS has been the gathering of information about the activities of specialist palliative care services, the Minimum Data Sets Project (MDS). In conjunction with and building on the excellent work undertaken by the Hospice Information Service, a joint organization between Help the Hospices and St. Christopher’s Hospice, the MDS provides valuable information on numbers of inpatient and home care services, hospital support service, and day care, as well as how these services are used (Table 66–2).

The 10 Marie Curie Centres or hospice inpatient units are administered by a national charity, Marie Curie Cancer Care. In 2002–2003, there were some 3666 inpatient admissions. Additionally, there are thousands of nurses who care for patients in their own homes for a full working day or night shift. The presence of a Marie Curie Nurse often allows patients to remain at home. In total, they provide some one million hours of nursing care each year.

Sue Ryder Homes are administered by a national charity, the Sue Ryder Foundation, providing palliative care for patients with cancer in their homes. Several homes have visiting nurses who visit patients before and after admission.

The growth of hospice services in recent years has been considerable. In the early 1970s, The Cancer Relief Macmillan Fund began a program of capital funding to provide units within NHS hospitals, or on their grounds, with hospital authorities ensuring the responsibility for their running costs.

The number of adult inpatient hospice, community, and hospital-based services, although adequate in some areas, is variable and inequitable throughout the country. A survey undertaken by the NCHSPCS highlighted this variation. In Wales and Scotland, the provision to remote communities relies largely on community teams and hospitals. Out of a total of 434 inpatient units currently providing care, there are just 34 in Wales and 46 in Scotland (see Table 66–2). There are now 51 beds per million adult population.

Much is owed to these inpatient institutions. They broke new ground with their nonhierarchical teams of professionals and volunteers, incorporating patients’ needs and wishes into the care that they gave. Hospice involves “a personal noninstitutional approach, promoting psychological care and physical well being through good symptom control.”

The voluntary units include 10 Marie Curie Hospices and 6 Sue Ryder Homes. The remainder are independent local charities including 2 exclusively for HIV/AIDS.
The growth of number of hospices catering to the terminally ill child and family has been remarkable throughout the last decade and a half. There are 30 listed in the current edition of the Hospice Directory (Table 66–3).28

Patient statistics for 2001 reveal that 41,000 new patients were admitted to an inpatient unit. Ninety-five percent of these were suffering from cancer. There were 29,000 deaths, and the average stay was 13 days.28

Range of Services

The range of services offered by hospices is now considerable, the day long past when hospices cared only for the patient requiring terminal care. Johnson and colleagues reported that “our findings suggest that their [patients] management is likely to include a range of investigations and procedures that are usually associated with acute hospital care.”30 Hospices routinely admit patients who are having chemotherapy and radiotherapy for their cancer. Transfusions of blood, and rarely platelets and other blood products, and injections of bisphosphonates either as a day case or overnight inpatient admission are performed. Proponents of this rather more accommodating and enabling position feel it important that patients see hospices as places where they can be successfully treated and discharged. Critics believe that we are in danger of losing much if we forget the original binding ethos and principal aim—the holistic care of the dying—in the rush to diversify and to be seen as therapeutic, a process universally known as the “routinization and medicalization of hospice.”

Much attention has been given to an integrated care pathway for the dying, in particular the Liverpool Care Pathway for the Dying Patient,30a a multidisciplinary framework designed to coordinate care. Its implementation in hospital, community, and care homes has meant that a focused hospice model of care can be replicated. This pathway has been incorporated into the Gold Standards Framework33 and embraced by the NICE Guidance.23

Home Care

Table 66–4 illustrates the extent to which the majority of patients who receive specialist palliative care do so in their own home. In 2001, more than 150,000 patients were seen by home care teams, 3 to 4 months being the average length of time that a patient will be cared for by a team. A minimum of 60% of all cancer deaths are now cared for by these teams, with an estimated 30,000 deaths at home.28 The MDS for 2002–2003 records the reasons for referral to a community (home care) service as pain or other symptom control 43%; psychological support 38%; caregiver support 13%; social and financial help 7%; and assessment for admission to an inpatient unit 3%. A team of clinical nurse specialists (CNS), usually with medical support, will make on average 5.3 visits per

patient; the CNS will make 79% of visits recorded; medical staff 2%; and the others being made by professions allied to medicine, social workers, and other nurses. The average length of care given to a patient in the community is 118 days, although two thirds of those cared for are on the case load for less than 3 months.31

“Macmillan Nurses,” long a feature of the provision of specialist palliative care, are named after Macmillan Cancer Relief, which funds the first 2 to 3 years’ salary of these posts in community and hospital settings, with the understanding that the health authority will pick up the costs of these posts afterwards. The principal role of these nurses remains one of personally assessing and delivering care to patients and families, and giving advice to and empowering primary caregivers. However, this has evolved to one that promotes high standards of cancer and palliative care. This is achieved by acting as a catalyst and change agent; contributing to pre- and postregistration educational curricula, and promoting and participating in clinical research and audit.32

The Macmillan Gold Standards Framework, a framework for community physicians and their teams caring for the palliative care patient in their own home, is now being rolled out across the United Kingdom, with more than 500 practices in 56 project areas. Based around seven “gold” standards, the program offers evidence-based advice on:13

- Teamwork and continuity of care
- Advanced planning
- Symptom control
- Support of patients and caregivers

Hospice at Home

Extended nursing care at home, or Hospice at Home, is a service that employs registered and auxiliary nurses in the patient’s home, providing physical care and psychosocial support. Although the amount of time spent at home is small, it is thought that this type of service reinforces patients’ confidence to remain in their own surroundings and in their ability to stay there. Boulstridge and colleagues34 conclude from their retrospective study of 52 patients cared for by a Hospice at Home team that “Hospice at Home appeared to enable patients to die at home.” There was a primary need for caregiver respite. Hospital admissions were mainly for appropriate specialist palliative care; 26% had been admitted for symptom control and just one patient, 2% for terminal care.

Day Care

Day centers afford the chance for patients to express their creativity, to be among others in a similar situation, to provide both a social support and the opportunity to receive symptom control as required. They can serve as an important source of respite for patients and their carers.35,36 A questionnaire survey of 43 day centers aimed to investigate the two prevailing models of day care in the United Kingdom, the “social” model and the clinical or “medical” model.37 It showed that there were multiple reasons for admission to a day care program, but that respite for caregivers was the second most commonly cited reason. Others were psychological support, social interaction, and symptom control. An estimated 31,500 new patients attended day facilities in 2002–2003. Of the services that responded to the MDS, 19 had more than 15% noncancer patients. However, 21 services recorded that they did not have any noncancer patients. Fifty-nine percent of patients stayed with a day center for less than 3 months, while 23% stayed more than 6 months.31

Hospital Support Teams

Approximately 56% of cancer patients in England and Wales die in hospitals.39 Hospital support nursing services consist of on average 2.2 nurses31 based in hospitals, acting as a resource. Hospital support teams may have the support of a specialist doctor. Access to patients who require palliative care but who may be in a surgical, medical, or gynecological bed is vital, and a doctor facilitates this. In 2002–2003, there were an estimated 120,000 patients seen by these services.31 An evaluation of the impact of hospital clinical nurse specialists on other doctors and nurses showed clear benefits in the support and education that they were able to provide.39 Two important studies underline the importance of these teams. A study to evaluate whether a hospital team had an effect on the patients’ symptoms showed that they benefited from being admitted to the hospital for symptom control, and that they had better symptom control for pain and anorexia,40 while a study to assess the effect of the hospital team on cancer patients’ insights, showed that those patients who received input from a team had a better insight into their diagnosis and prognosis. This enabled more open communication about impending death.41

Some Issues Facing the Providers of Palliative Care

Criteria for Admission to Inpatient Hospices

Criteria for admission to what is, in effect, a valuable and limited resource, has always been an important issue for hospices.33 Admission is likely to be because the patient has symptoms in which the hospice can play an active part in treating, or because the patient is dying and the patient and/or their family believe that admission is appropriate.

A review of requests for admission are usually decided each working day by a small representative team of senior staff. They take into account the patient’s physical, psychosocial, and other needs; whether they live alone and who is at home to care for them; whether there are children in the house; and what packages of care are already in place. A visit by a member of the hospice’s medical staff may be necessary, but often there is little time to accomplish this. Many hospices have a businesslike understanding with their referring community or hospital-based teams, trusting their estimation of the patient’s prognosis, present condition, and needs.
A study of a random sample of people who had died in 1998 investigated which terminally ill cancer patients received inpatient care in hospices and other specialist palliative inpatient units. This study interviewed families and others who knew about the last year of life. Interviews were obtained for 2074 cancer deaths. Of these, 342 had been admitted to 31 different hospices. Five factors were found to independently predict hospice inpatient care: having pain in the last year of life, having constipation, being dependent on others for activities of daily living for between 1 and 6 months before death, having breast cancer, and being under the age of 85 years. A third of patients with all five factors were admitted, compared with no patients with none of these factors. It was found that symptom severity, age, dependency level, and site of cancer played a role in determining hospice admission but had limited predictive value. The study’s salutary conclusion was that “admission in determining hospice admission but had limited predictive severity, age, dependency level, and site of cancer played a role severity, age, dependency level, and site of cancer played a role in determining hospice admission but had limited predictive value. The study’s salutary conclusion was that “admission in determining hospice admission but had limited predictive value. The study’s salutary conclusion was that “admission in determining hospice admission but had limited predictive value. The study’s salutary conclusion was that “admission seems to be governed more by chance than by need.”

It is generally unlikely that a hospice will agree to the admission of a patient with a prognosis of longer than 3 months. In the United Kingdom, the complex social services banding procedures for estimating continuing care, residential and nursing home care mean that few hospices willingly admit patients who may require referral for this care on discharge.

Respite Care

Possibly the most common reason for admission to an inpatient unit at the end of life is the caregiver’s inability to provide continuing care. Despite the increasing amounts of palliative care available, studies have highlighted the high level of anxiety experienced by caregivers. The term “respite care” is a term that covers a range of services provided under the palliative care umbrella: inpatient care, day care, and hospice at home services.

The majority of hospices are able to admit for a period of 1 to 2 weeks to enable the family or caregivers to have a rest. The concept of providing this form of care is not new. Families who “battle their way through” the journey from diagnosis to death and beyond require considerable information from the palliative care team and attention to their emotional and health needs. They need empowerment to undertake their role. Identification of family members who may not cope well in the bereavement period is important so that resources can be mobilized in a preventive manner. This is often achieved by the home care team, but the admission of a patient for respite care enables the caregivers to be introduced to staff who will be there to care for them later on. However, there is little evidence for the clinical effectiveness of inpatient beds for respite care.

The problems associated with respite admission have been well identified. That this group of patients may be “blocking” a bed needed for a terminally ill patient taxes most inpatient units and ensures that staff carefully plan these admissions, and that restrictions are often placed on the numbers of such admissions that a unit can take at any one time. Raeside and Ellershaw, in their retrospective analysis of 34 respite admissions to St. Christopher’s Hospice, found that patients admitted were enabled to receive a range of services, including anesthetic referral. However, 24 (71%) died during the admission in the hospice or during a subsequent admission.

The place of day care as a means of providing support to the caregiver by ensuring that a patient achieves a regular, often weekly, day admission and break from their routine, while established and cited as the second most common reason for referral, is none the less poorly evaluated. The effect of the increasing amount of support at home, either provided by hospice services, national cancer charities, or local voluntary bodies is similarly probably underestimated because of inadequate sample sizes and a problem with the definition of this care.

Single or Shared Accommodation

Many hospices in the United Kingdom, following a model first promoted at St. Christopher’s, placed their patients in bays of two, three, and four beds. Kirk, in a search of the literature prior to undertaking his study, found no reference to room choice in a hospice “or why the people who are influential in hospice ward design chose the bed configurations they did.” Following criticism by the regulatory body, the Care Standards Commission, and an appreciation that many patients prefer single rooms, many hospices are undertaking extensive redevelopment works to supply more single rooms. Kirk established that 21 out of 24 patients preferred a single room, especially if they had distressing symptoms such as nausea and vomiting or diarrhea. Contrary to common belief, there was no evidence to support placing patients together to share their experiences. There is anecdotal evidence that placing short-term patients alongside those who are terminally ill is detrimental to their overall well-being. Many patients report being distressed and subsequently reluctant to be readmitted. Further research into the effects of placing patients for short-term admission—for example, for respite or rehabilitation—alongside those that are dying is required.

Ethnic Minorities

The need to meet the needs of all cultural and ethnic groups residing within a hospice’s catchment area is recognized by a movement anxious to help hospice shed its white, middle-class image. After all, a hospice not only serves, but also depends on its local population. Information from the Hospice Information Service shows that of those cared for by palliative care services in 2001–2002, just 3% were nonwhite. That there is a poor uptake by ethnic groups was a cause of concern highlighted in the NHS Cancer Plan. The National Council for Hospice and Specialist Palliative Care Services’ report, Opening Doors, attempted to identify the extent of and reasons for low uptake of hospice and specialist palliative care services and tried to ensure that those purchasing and providing these services were aware of ways in which the service could be improved. Fountain, in his 1999 study of palliative care uptake in the city of Derby, found that whereas ethnic minorities made up 9.7% of the population, they accounted for only 1.5% of the patients referred to palliative services.
care services. The NCHSPCS report had found that the ethnic minority population had a lower proportion of elderly people and the incidence of cancer in the black and Asian communities was lower than that of the indigenous white population, a conclusion reached by other authors.49,51

Another concerning reason why ethnic minorities may use palliative care services less is that the services are "culturally insensitive."52 The reluctance of GP's and other health care professionals to refer patients, the lack of information about the availability of services, and poor communication exacerbated by poor translation services were some of the reasons cited for this "insensitivity." As the authors state, it is indeed fortunate that Oliviere, among others, offers specific advice to "nurture and respect cultural difference."53 Perhaps the best current advice is that of Sheldon, who states that an application of "the individual and whole person approach basic to palliative care, which inquires of the patient and caregiver what their goals are and makes them central, is still the most appropriate."54 However, the providers of palliative care services still have some way to go to appeal to ethnic minorities and to not appear exclusive.

Dying from Other Diseases

The use of hospice and specialist palliative care services by patients without a cancer diagnosis is another important issue for and measure of a service that is openly diversifying and trying to shed its old image. For those with a noncancer diagnosis, palliative care is most likely to be delivered by a primary care team. Provision of specialist palliative care to this group is rare but becoming increasingly less so. In the past, few services advertised their willingness to extend their services to the noncancer patient; however, many are changing their mission statements and broad service objectives to include patients with a "life-threatening illness." However, the percentage of new patients admitted to hospice inpatient units remains very low, just 4.9%, and to home care programs, just 4.8% in 2002–2003,51 little different to that of 1994–1995, 4.4%.54 It would appear that the United Kingdom is not following reported evidence from the United States by treating and caring for a larger percentage of this group.55 However, it is recognized that the needs of this group of patients is essentially the same as that of advanced cancer56 and anecdotally few are now denied access to specialist palliative care. Addington-Hall and colleagues, writing one of a series of papers highlighting the need of this group, states that to answer the "question of how to meet the palliative care needs of people who die from causes other than cancer will require the qualities of imagination, innovation and dedication which have characterized the hospice movement over the past 30 years."57 It is good to report anecdotally that nurses in home care, day care, and inpatient units do understand these needs and, using these qualities, are becoming more and more skilled in addressing them.

Cardiopulmonary Resuscitation

Cardiopulmonary resuscitation (CPR) remains a difficult issue for hospices. The debate has intensified since the publi-
has not always achieved the status that it requires in the United Kingdom.

Despite these seemingly formidable obstacles, there are now many palliative nursing academic departments in the United Kingdom. The Palliative Care Research Forum of Britain and Ireland has been in existence since 1991. In 1996, the Association of Palliative Medicine formed a science committee, and The Royal Society of Medicine created a Palliative Care Forum in 1997. The growing number of palliative medicine specialist registrar training programs and the 10 medical, nursing, multiprofessional, psychosocial, cancer, and palliative care Masters programs require that the implementation of research is addressed and that a body of knowledge continues to be assimilated. The multiprofessional journal Palliative Medicine, established 15 years ago and now in its 18th volume, has consistently published research from the United Kingdom and Europe, doing much to ensure the credibility and effectiveness of research among all disciplines and in all palliative care settings.

The continuing need for providers of palliative care to engage with the commissioners of health service delivery has meant that they have had to embrace their reforms and priorities to establish outcome and effectiveness measures. It is not easy to apply an evidence-based approach to palliative care for some of the reasons above, and as Higginson has noted, an absence of evidence does not mean that a service is ineffective. The NICE guidance for supportive and palliative care emphasizes that “Future research should focus on determining effective solutions, rather than re-assessing need; there is a wealth of evidence on need and importance, and a relative dearth on effective solutions.”

However, as Clark notes, “although research has been stimulated by developments in the health service and by the development of cooperative and supportive links between researchers, the research base of palliative care is insufficiently rigorous, often failing to move beyond small-scale descriptive accounts.” He optimistically concludes that “there are . . . signs that there is a sufficient volume of established researchers and research units to begin to move beyond the situation.”

### Regulation of Hospice Services

The regulation of hospices and specialist palliative care services has long concerned nurse managers. Under the Nursing Homes Act (1984), a convenient place to lodge a facility that did not fit in with the mainstream hospital sector, hospices found that they were both overregulated and burdened by the regulations that apply to nursing homes, be they for six beds or 60. It did not reflect the comprehensive, multiprofessional work that palliative care services provide. The regulation and inspection teams were interested in inpatient facilities only, not in the important work in the community and how it impacted on these facilities. The present government undertook evidence and published its proposals for the provision and regulation of services in the independent sector. These Care Standards set up a separate regulatory body to set and inspect hospices against new, defined standards. Many were looking forward to the implementation of these new standards as an opportunity to fully and appropriately demonstrate the complexities of palliative care. Some 2 years after their introduction and just when the Care Standards inspectors are coming to grips with the palliative environment, these standards are being abandoned. In the future, we will be inspected by the Health Care Commission.

### User Involvement

Olivieré69 reminds us that involving the users of palliative care was integral to its founding, and that Dame Cicely Saunders, in recounting her original vision, felt that the hospice movement should be “a voice for the voiceless.” There are potential and real difficulties in transferring the concept of user involvement to palliative care, including the nature and effects of a rapidly changing disease process, patient symptoms, and concerns about their families, finances, and the future, which must take precedence. Talking openly about death and dying and the protection of patients by professionals is also paramount.70,71 Bradburn72 writes that user involvement in the context of palliative care requires that we listen to users’ experiences, empower users to advocate on their own behalf, and work with user groups in partnership. A report into the users forum at St. Christopher’s Hospice concluded that although the entire process was time-consuming, the forum for both professionals and users had been “exciting, educational and stimulating.”73 It is now understood that participation by users cannot be a token exercise, and that their input is required when considering the development of hospice services. Certainly, despite the barriers and challenges to establishing an effective means of obtaining user feedback, there are now many successful initiatives in the United Kingdom72 to ensure that the user voice, the “voice for the voiceless,” is heard.

### Conclusion

It would seem appropriate to conclude that, with the advent of the NICE guidelines for palliative and supportive care, our specialty, at least as far as it practiced in the United Kingdom, has “arrived” and gained its proper footing. However, despite assurances that a long-term framework for funding will be developed,74 concerns remain that the provision of palliative care can be maintained in its present format.75 “Agenda for Change,” a grading and pay system for all clinical staff in the NHS, is just the latest package of proposals to affect how palliative care is provided. The main providers of palliative care, independent hospices in the charitable sector, are faced with the prospect of losing staff to the NHS if they are unable to meet the new terms and conditions, but of a prohibitive financial bill if they do meet them.76 The ongoing problem of an aging workforce and continued nursing shortages in the United Kingdom77 place further pressure on the provision of care, and make it imperative that the
specialty is both competitive and attractive to prospective nurses.

At this time, it appears redundant to some to again debate the name of our specialty to embrace "supportive care" and to be concerned about our image. "Patients are not interested in the name of our specialty but in what we do, how compassionate we are, how well we communicate and whether we demonstrate concern for their relatives." However, if we are to continue to matter to patient groups other than cancer patients and to make an impact on the potential purchasers of our care, we will have to be clear about who we are and what we stand for. Although there is continuing debate in the United Kingdom, there is little ambiguity of purpose and plenty of goodwill and resolve to see that palliative care continues to grow and to assume its rightful place, remaining an influential force in nursing.

REFERENCES

quality of life of patients and their families facing the problems associated with life-threatening illness, through the prevention and relief of suffering by means of early identification and impeccable assessment and treatment of pain and other problems, physical, psychosocial and spiritual. These aspects are specifically emphasized in the recently released document on palliative care from the Council of Europe, Committee of Ministers: “Recommendation REC (2003) 24 of the Committee of Ministers to Member States on the Organization of Palliative Care.”

Palliative care should be offered at all levels in the health care system and could be regarded as an integral part of all medical services. However, based on the above, it becomes evident that palliative care has its own special characteristics that are not entirely covered by the mainstream health care system. Thus, the emergence of palliative care as a medical specialty is rapidly progressing, and palliative medicine has already been acknowledged in some countries as a specialty.

In the Nordic countries, a 2-year training program for a specialist program was started in 2003—with too many applicants. The course is composed of six 1-week slots of teaching, with working assignment in the intervals. All participants conduct a small research project and write a paper for publication, preferably for an international journal.

The scientific advances in cancer therapy have not lead to a dramatic reduction in cancer incidence. The mortality rates have remained relatively stable or slightly decreased in the western world. Because palliative care goes far beyond opioid availability and pain treatment and encompasses all the key elements of the holistic nursing approach—the care needs, the suffering, and the dignity and the quality of life of patients and relatives towards the last stages of life—it seems inappropriate to draw artificial lines between disease-modifying therapy and palliative care. This becomes even more evident when we know that most cancer patients are not cured from their disease, and that palliative care should, in fact, be offered early in the stage of disease to provide the essential part of this care to all patients. Thus, the development and improvement of palliative care is an important, growing, and large public health issue across nations and cultures.

The purpose of this chapter is to present some of the European experiences with respect to the organization and delivery of palliative care, educational issues, and research.

**The Situation in Europe**

Due to increasing life expectancy and declining birth rates, the age distribution in many European nations is skewed toward a larger proportion of older people. Because the overall cancer incidence rises with advanced age, more people with cancer are expected in the near future. Predictions for causes of death in Europe for the next 15 years also show a changing pattern (Table 66–5), with more people living with and dying from chronic diseases.

Although different diseases present with various symptoms along the illness trajectory, epidemiological studies show that many symptoms and problems in the last year of life are similar. This represents a challenge to the health care systems in the delivery of effective and adequate end-of-life care to an increasing number of people.

Europe has gone through great political changes in the last decade, economically and culturally. In spring 2004, 10 new countries became members of the European Union (EU). How to best develop palliative care across Europe is still a challenge due to the great diversity of economic, cultural, and health policy aspects, as well as the significant differences in population size, from 4.5 million in Norway to 82 million in Germany. Nevertheless, the gradually increasing medical and scientific collaboration across borders has led to the development of various models for palliative care. Some European centers are influenced by the Canadian model in Edmonton, the Beth Israel Medical Center program in New York City, or by the WHO project on palliative care implementation that influenced the development of palliative medicine throughout Spain.

However, directly adopting a model from another nation with a different health care system is not always feasible. An example of this is the integration of the departments of pain service and palliative medicine into one, as has been successfully done at Beth Israel in New York. The pain programs in Europe are very closely linked to anesthesiology, and, as such, not only are caring for palliative care patients but also taking care of patients with postoperative pain, chronic nonmalignant pain, chronic back pain, etc. Although pain treatment is an essential part of palliative care, the linkage between departments in Europe is more often based on cooperation and consultation services and, to some extent, translational research. Several services in Europe have begun either from pain/anesthesiology and/or oncology teams.

most successful programs have been able to combine the skills and knowledge across specialties.

A survey of all European countries was undertaken in 2003 to provide an overview of the national palliative care activities with respect to implementation of palliative programs, finances and funding, delivery of care through palliative care units/hospices/home care, education, specialist training, and research. There has been a gradual growth in this medical field during the last 3 decades, with significant innovations in the last 10 years. The first national palliative care units (PCU) were opened in Great Britain in 1967, in Cyprus in 1974, and in Norway in 1993. Germany, France, Poland, and Finland followed before 1999; after this Romania, the Netherlands, Belgium, Hungary, Portugal, Austria, Switzerland, Slovakia, Denmark, and Luxembourg all established their units before the change of the millennium. However, the survey revealed major international as well as intranational variations with respect to most of the issues that were evaluated.

To place palliative care on the health policy agenda, strategic interventions based on evidence-based knowledge and consensus among international experts in the field are mandatory to gain the necessary influence. This can be achieved through the establishment of professional organizations, such as the European Association for Palliative Care (EAPC). The EAPC was established in 1988 with 42 members, on the initiative of Professor Ventafridda and the Floriani Foundation in Italy. The aim of the EAPC is to promote palliative care in Europe at the scientific, clinical, and social levels. In 1998, the EAPC was awarded the status of Non-Governmental Organization of the Council of Europe. The EAPC has participated in two Expressions of Interest presented to the European community for the EU 6th and 7th Framework Research Programs.

As a result of this work, the issue “Innovative Research on Palliative Care in Advanced Cancer Patients” is included in the thematic priority area number 1, and as such put on the agenda for advanced research. These are great opportunities to come forward with priority topics for research.

Criteria for Excellence

There is currently no universal European consensus regarding indicators for a center of excellence in palliative care. The national models for delivery of palliative care are not identical, and they are not prioritized uniformly in each country. Because of the relatively large economic, political, and cultural diversities, for example, between the former eastern states and the rest of Europe, between the southern and northern parts of Europe, as well as within nations such as Italy, it might not be feasible to aim for the implementation of one particular model of excellence everywhere. On the other hand, there are certain criteria that should be included in all models of palliative care to ensure the sufficient comprehensive provision and quality of care. These criteria include:

Delivery and content of care:
- Inpatient professional palliative care services in PCUs or hospices
- Outpatient palliative care services or home care, organized by the PCU or through the established health care services
- Size of the unit and patient case mix
- Multidisciplinary approach
- Consultation services

Figure 66–4. The integrated palliative care model in Trondheim, Norway.
Education and advanced training:
- Basic levels, medical/nursing schools
- Continuing medical/nursing education
- Palliative medicine specialists, palliative care nurse specialists
- University chairs of palliative medicine

Research:
- Continuous evaluation of the quality of palliative care services (structure, process, delivery)
- Evidence-based knowledge to provide guidelines for treatment
- National and international multicenter studies
- Translational research to close the gap between basic sciences and clinical practice
- National and international networking

Integration of palliative medicine and care in public health care:
- Policy, advocacy, lobbying

At the University Hospital in Trondheim, a fully integrated model has been developed during the last decade (Figure 66–4). The program started with the development of a 12-bed inpatient unit (acute palliative care) and an outpatient program, including a consultation service at the various wards and departments at the University Hospital. The staff is interdisciplinary—with highly trained nurses and doctors. A close collaboration with the city of Trondheim (a 12-bed nursing home unit at Havstein) has been established as an integrated unit of the palliative care program, combined with specialist palliative care service in patients’ homes in collaboration with the general practitioner’s (GP) and home care nursing program in the community. The pain clinic and the palliative medicine unit are increasing their clinical, educational, and research collaborations.

**EAPC Activities: An Example of International Networking**

The EAPC serves as a catalyst for this work, through the steadily growing number of activities and task forces (Figure 66–5).

The delivery aspects are addressed by the EAPC Task Force on Palliative Care Standards and the EAPC Task Force on Palliative Care Development in Europe. These task forces are established through initiative from the EAPC members and recommended by the board of EAPC. These working partners are time limited, with an expectation to deliver a program that can be followed up by the member states. The aim of the first one (Palliative Care Standards) is to identify the needs for some form of European standard and to create a checklist for others to follow. The second task force aims to achieve an overall vision of the care activity and development of the different palliative care teams in Europe. A new task force that was established in 2002, EAPC Task Force on Palliative Care for Children facilitates and supports the work of pediatric palliative medicine and provides a link between palliative care for adults and children.

Education and research are imperative for palliative care to become acknowledged as a medical specialty. The EAPC task forces on nursing and medical education are in the process of developing recommendations for the curricula on basic educational levels, as well as at the advanced and specialty levels. The EAPC research network was founded in 1996, based on the fact that research is a key issue for palliative care, a collaborative effort that has resulted in several scientific publications, international studies, and the organization of three research congresses—in Berlin in 2000, in Lyon in 2002, and in Stresa in 2004.

The major aims of the EAPC East project, which was established in 2001, are to support and to improve the development of palliative care and to coordinate the activities and initiatives in Eastern Europe. In most of these countries, the care is unevenly distributed and poorly developed, and drugs such as opioids are not readily accessible everywhere. In Romania, for example, a GP must write and request the drug from an oncologist, who, in turn, has to send a letter of recommendation for approval to the health authorities. An approval is valid for 3 months, but the prescription from the GP is only valid for 10 days. The drug is not in stock in all pharmacies, and if the medication needs to be changed, the entire procedure must be repeated. By building a network of people and organizations interested in and working with palliative care in Eastern Europe, palliative care is put on the health policy agenda.
a prerequisite for funding and change of practice. The development of educational, training, and twinning projects between EAPC member institutions and Eastern European health care professionals constitutes a major part of this work, as well as the identification of national and international donors for hospice and palliative care development.

A current example is the joint European project to disseminate the recommendations from the European Council for widespread use by professionals, health care administrators, politicians, and the public. The peak in this work WAS in the fall of 2004, by media campaigns, seminars, and discussions of the Council of Europe documents and the recommendations from EAPC and national organizations. The work is organized through the EAPC-East office in Stockholm in collaboration with local palliative care organizations that will translate, print, and distribute the recommendations—an important tool for information and lobbying. The relevance of this work in relation to the Romanian drug example above is highlighted by the statement in the EC recommendation: “legislation should make opioids and other drugs accessible in a range of formulations and dosages for medical use.” The following countries are included in the project: Albania, Armenia, Azerbaijan, Belarus, Bosnia-Herzegovina, Bulgaria, Croatia, Czech Republic, Estonia, Georgia, Hungary, Latvia, Lithuania, Macedonia, Poland, Romania, Russia, Slovakia, Slovenia, Ukraine, and Yugoslavia.

Ethical issues are central in palliative care; the EAPC task force on Ethics and Euthanasia completed its work in 2003. The principle aim of this task force was to revise the EAPC’s statement and judgment of palliative care and euthanasia. These issues created much debate; the original paper with comments is found on the website: http://www.eapcnet.org/projects/ethics.asp. The guidelines have been translated into French, Italian, Hungarian, German, and Greek, with other languages in the pipeline. The EU-funded research project PALLIUM is also concerned with the elucidation of ethical principles within European palliative care services and has finalized specific country reports from a survey undertaken in 1999.

Delivery of Palliative Care

Models

As pointed out earlier in this chapter, the organization and delivery of palliative care in Europe is unevenly distributed. A recent survey showed that there were no PCU beds in 35 of 53 administrative districts in one German region, while five districts had from 31 to 45 PCU beds per 1 million inhabitants. The Spanish region of Catalonia has about 46% of the nation’s palliative care programs but only 15% of the entire Spanish population.

Palliative care is delivered through various channels, and the degree to which it is integrated, coexisting, or separated from the formal health care system varies considerably. In many countries, health professionals, as well as volunteers, private, charitable, and religious organizations, in primary care and through general hospitals carry out much palliative care. In Spain, for example, private organizations are providing home-based palliative care to a substantial number of people, and likewise through volunteers in countries such as Hungary, Italy, and France, while there is little tradition for volunteer work as a separate work force in the Nordic countries. However, with the increasing knowledge and recognition of the complexity in the symptomatology of incurable diseases, a common model of providing care in Europe has been to concentrate expertise in multiprofessional teams, who work in hospitals, inpatient units, hospices, or in the community in direct patient care or as consultants. To fully integrate palliative care into the general health care system, political guidelines from the health care authorities are prerequisites. In 2001, the Italian National Health Service passed a law saying that palliative care programs should be provided for free to patients and families, building on a previous law on hospice development that was followed by a budget allocation to the regional administrations. Several other European countries such as the United Kingdom, France, Norway, and Spain also have health policy directives on palliative care implementations.

An all-inclusive and comprehensive overview of all European centers is not possible to present. Because the statistical and reporting guidelines vary too much, it is difficult to obtain sufficient documentation to perform valid comparisons across countries at the same time, and the field is rapidly developing—maybe a quality criteria in itself! Table 66–6 presents the activities of 11 centers in Europe according to the previously mentioned criteria.

Comprehensive Care

Most studies on delivery of care uncover the importance that patients and families place on receiving a well-organized package of care. Quite often these professional teams take care of the most advanced patients, with complex symptomatology and rapidly changing needs. Despite this, there is evidence that such specialized teams are effective in relieving distressing symptoms and can improve the quality of life of the patients and families towards the end of life. Research-based knowledge from studies concerning patient preferences in relation to end-of-life care shows that up to 75% of respondents would prefer to die at home. Scandinavian trials on different ways of coordinating palliative care services across the different settings of hospital, home, and community have found that a higher proportion of people can be helped to remain and to die at home as they wish to, and to spend less time in nursing homes.

Most European palliative care centers have a limited number of inpatient beds, ranging from 4 to 40, as shown in Table 66–6. This is in line with the numbers in Figure 66–6, demonstrating an insufficient coverage of PCU and hospice beds on national levels in some European countries in 2003, ranging from 20 to 50 per one million inhabitants.

Overview of Some European Palliative Care (PC) Centers (continued)

| Country          | Name                                                                     | Palliative Care Unit (PCU), Size, Team Composition* | Outpatient Unit | Home Care† | Patients          | Education/Training Consultation Services                                                                 | Research                                                                                      | Specific Activities                                                                 |
|------------------|--------------------------------------------------------------------------|-----------------------------------------------------|-----------------|------------|-------------------|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| Norway, Trondheim| Seksjon lindrende behandling (SLB)                                       | Acute PCU, 12 beds, plus 12 beds in one nursing home Multidisciplinary team: doctors, nurses, social workers, physical therapists, dietitians, chaplains | Yes             | Yes        | 99% cancer patients | Continuous PC education and training for medical students, physicians, and nurses in collaboration with the university Regular internal education, courses, and training on basic/specialist levels Consultants in other units, home care and the nursing homes | Close link to the university, chair in palliative medicine Specific research seminars, high degree of translational research, substantial scientific publications on PC every year Multidisciplinary, several PhD students |
| Spain, Barcelona | Institut Català d’Oncologia                                               | Acute PCU, 16 beds Multidisciplinary team: doctors, nurses, social workers, psychologist, psychiatrist, physical therapist | Yes             | Yes        | All cancer patients | University hospital support team to serve other units Individually based continuous education and training for staff Master of PC located on site, doctors/nurses | Active research department, center based and multicenter studies Multidisciplinary research | CATLAN (Catalan multicentre cooperative group), 1998, design of studies and trials |
| Sweden, Stockholm| Stockholms Sjukhem (SSH)                                                 | Acute PCU, 40 beds (20 × 2) Multidisciplinary team: specialist doctors in oncology, geriatrics, algology, neurology, internal medicine, nurses, social workers, physical therapists occupational, therapists, chaplains | Yes             | Yes        | The PCU of the SSH has a majority of cancer patients | Continuous PC education and training for medical students, physicians, nurses in collaboration with the university One medical training position Continuous education and courses for staff members, external courses for nursing home staff, physicians in specialist training during specific 1 week courses. Collaborating with the university, chair in palliative medicine Specific research seminars Substantial scientific publications on PC every year Multidisciplinary research, several PhD students | The Swedish Palliative Network (SPN), a web-based information service developed and based here The EAPC East Coordination Center based here The web-based research tool PANIS, a multi-center data collection system developed and based here |

*No differentiation between part time and full time employment
†Defined as PC services provided out of hospital by the PC team
Palliative care models encompass the provision of comprehensive care, and most centers presented in Table 66-6 also have outpatient/day care facilities and home care services. However, there is no universal way of delivering this, because the national health services are organized and reimbursed for this work in different ways. In many PCUs, the hospital palliative care teams provide direct patient care after discharge (see Table 66-6). In certain parts of Spain, private organizations have a car service to take palliative experts from the hospital to the patients’ homes. In Norway, as another example, there was no tradition for physicians to leave the hospital to take care of the patients at home. The financial system was prohibitive of such activities, with no reimbursement for extramural activities. Through intense and evidence-based lobbying, however, local politicians were convinced that the hospitals, not the individual physicians, should be reimbursed for this work. Thus, the Trondheim model was implemented in one region, enabling more people to stay in their homes. In the Netherlands, on the other hand, the home care services are generally well functioning, and the hospital palliative care teams basically serve as a facilitator and consultant to ease the transition between the PCU and the home. A Dutch evaluation showed that the team served the needs of the professional caregivers in a variety of settings, and that most consultations concerned physical and pharmacological problems.

Some of the PCUs in Table 66-6 are closely collaborating with nursing homes, for example, in the Netherlands and Norway, as recommended by Norwegian governmental committees. Extending intensive services to sites of more traditional care represents a challenge on the political, personal, organizational, economical, and educational levels. Hospitals and nursing homes often have different budgets, and cost containment might be difficult when expensive drugs, fluids, and transfusions become part of daily care. This also increases the workload for the PCU care teams with respect to direct out-of-hospital patient care, extended consultation services, continuous, and specifically designed educational programs.

The increased demand for multidisciplinary teams is directly related to this.

**Multidisciplinary Approach and Consultation Services**

The increasing complexity of the tasks involved in palliative care makes it obvious that multidisciplinary teams are necessary in the identification and interventions to the rapidly changing needs of patients and families. Professionals in specialist palliative care settings may form relatively permanent teams, as is the case in most of the European centers presented in Table 66-6. Physicians, nurses, physical therapists, and social workers are included in most teams, supplemented by psychologists, psychiatrists, dietitians, bereavement counselors, chaplains, and others. Depending on the context of care, the individual team professionals also may serve as expert consultants for palliative patients in other hospital units, the home care service, and nursing homes. The situation may also be the opposite, with palliative care teams seeking specialist services in disciplines such as neurology, anesthesiology, and pharmacology. Continuity of care across the PCU/hospice/home care interface is more easily achieved through a multidisciplinary team composition, if the responsibilities and strategies for the care plan are agreed upon. Again, the earlier the patients are seen with this holistic interprofessional approach, the more adequately their needs might be met. Another major advantage of the multidisciplinary teamwork is the aspect of bereavement care of staff, in cases with bereavement overload, an area traditionally better managed by professions other than physicians. The increasing numbers of professions involved in palliative care is directly reflected in the membership of palliative care organizations. The German Association for Palliative Medicine was founded by 17 physicians in 1994, while there were 50% physicians and 40% nurses among the 1100 members in 2003. At the EAPC 2004 Research Forum, there were 76% physicians and 11% nurses among the 449 attendants who had reported their profession, in contrast to almost 100% physicians at the first forum in 2000.
Education and Advanced Training

Rapid progress in the growth of professionals interested in palliative care began from 1995/96 and onwards. This is evidenced by the steadily increasing number of members in the EAPC, from around 7000 in 1995 to more than 50,000 in 2002 (Figure 66–7).

However, the link between academics and palliative care has only slowly progressed, by establishing palliative medicine as a formal part of the medical programs at a university level. Academic positions in this field can be found in 10 European countries (Belgium, United Kingdom, Germany, Finland, Greece, Norway, Poland, Sweden, Netherlands, Italy). Teaching in palliative medicine is on the curricula for medical students in Germany, Norway, Sweden, Finland, France, Greece, United Kingdom, Poland, Spain, and Hungary, while formal training as palliative medicine specialists can be found in United Kingdom, Romania, Poland, Germany, Norway, Sweden, Denmark, Iceland, and Finland. Specialized palliative textbooks in indigenous language are available in 12 countries. The situation is basically the same for nursing curricula, with few countries having palliative care as formal parts of the graduate or postgraduate levels or as an accredited specialization.

The recent extension of the EU has led to a more flexible employment market, with less restriction on crossing borders for work. A priority of the EU to facilitate this flexibility is the process towards more universal educational programs. Revising the different medical school curricula and the postgraduate specialist education programs to make them more standardized is an example of this.

Palliative Care Research

Palliative care had its origin in the hospice movement emerging in the United Kingdom in the late 1960s. For quite some time, it was erroneously believed that research had no priority in this context. However, the great advances in the attitudes on cancer pain and the speech by Cicely Saunders in 1965 makes it clear that this ideology was based not "only on compassion but equally on skills preferably founded on scientific evidence."22,23 Research in the relief of distress to raise the general standard, and the collaboration with other experts in medical science, such as pharmacology, were the means to reach these goals.

The Need for Research

Research is indispensable for the further development and improvement of palliative medicine.24 However, research is poorly embedded in this culture, partially due to the traditional focus on compassion and partially because research has relatively loose priority in routine clinical activity. The lack of scientific medicine in nursing homes and hospices further adds to this. Nevertheless, there is an increasing demand for documentation on quality and costs of care, through scientifically based evaluation of outcomes. In palliative care, there are many obstacles to the prioritization of research, methodological and clinical, in addition to the more attitudinal and ethical aspects. Based on experience, however, most patients are willing to participate in various topics of palliative care research, including randomized trials on the impact of palliative care services25,26 and evaluation of pain programs27 and palliative radiotherapy.28
Evidence-based Medicine (EBM) and Palliative Care

A definition of EBM states that it is the conscientious, explicit, judged use of the best available evidence in order to offer the patient the most optimal individual care. Thus, retrieving and applying the best available evidence should be an important part for every clinician in the preparation of strategies for diagnostic workup and treatment of patients. As such, there should be no contradictions between the philosophy of palliative care and EBM, although this debate has been going on for decades.

Many of the decisions made in palliative care are based on inferior quality studies, clinical experience, or extrapolation from studies performed in other populations, as is often the case in pain management. Thus, the need for EBM in palliative care seems evident. Treatment of patients with a complex pathophysiology is dependent on research that focuses on the specific patient population and their problems. This includes clinical trials, as well as basic and translational research. Areas that need more in-depth studies are related to cancer and non-cancer pain and symptoms, barriers to accessing care, differences in the social, psychological, cultural and spiritual aspects of palliative care from the point of patients, relatives and caregivers (Table 66–7). One example is related to the fact that most patients in palliative care are elderly. This is in contrast to most studies in mainstream oncology, internal medicine, and even in pain treatment, where the upper age limit often is 70 to 75 years. The validity of extrapolating data from these age groups into older populations is highly questionable, and the need for appropriate research programs in the elderly is warranted.

Research Collaboration

National or international multicenter collaborative studies are prerequisites for obtaining sufficiently large samples. The EAPC research network has established particular collaborations both in the area of clinical and basic scientific studies, including the combination of clinical data with pharmacology (phenotyping) and genetic mapping (genotyping). Eleven expert working groups have been working on various topics for which a universal European consensus is warranted. An example of this is the EAPC recommendations on morphine and alternative opioids in cancer pain.

Important information for palliative care providers as well as for policy makers might be gained by exploring already existing data on palliative care. This includes evaluation of different models and the huge variation in costs of care, the spending on palliative care vs. other health care, whether people die in hospices or in home care, and more. This might be facilitated through networks such as the EAPC, through channels for communication and education such as telemedicine for educational and consulting purposes in Norway, or through new national European databases such as the OICP (Italian Observatory of Palliative Care) and PANIS (Palliative Assessment Network in Sweden). The OICP is a website (http://www.oicp.org) with two main contents: a directory of all Italian palliative services and a research center with annual exclusively online surveys on palliative care issues. The PANIS network (http://www.panis.se) conducts semiannual nationwide e-mail surveys on prevalent symptoms, with rapid online feedback to attending physicians.

The European Way to Promote Research

Many of the European centers presented in Table 66–6 were engaged in research activities on various levels. To successfully integrate multidisciplinary research in a palliative care program, certain criteria have to be accomplished:

- Professional leadership
- Agreement on and promotion of a clear strategy and research agenda
- Parallel development of clinic and research
- An infrastructure that ensures interaction with scientists not working in the palliative field
The pain and palliation research group in Trondheim, Norway is an example of a multiprofessional group that is active in international collaboration (see Table 66–6). Main areas are ethics, communication, subjective assessment, pain and opioids, and symptom palliation. Several PhD students are pursuing their dissertations in this group, and 54 scientific papers have been published over a 3½-year period. The Instituto Tumori in Milan and the Dutch university hospitals in Table 66–6 are other examples of successful collaboration between research and clinical palliative work.

An ultimate goal should be to ensure that palliative care is represented at all local and national research forums. For Europe as a whole, it is essential to promote the inclusion of palliative care research within the EU framework.

**The Challenges**

Although palliative care in Europe has undergone a remarkable development from its start in the 1960s to the beginning of a new millennium, there are still several challenges ahead. As we have demonstrated in this chapter, there are still major differences within Europe. During the preparation of this chapter, we inquired as to how palliative care is organized in various countries in Europe. Written responses and oral communication indicated that there is no clear definition on what is meant by a palliative care program or what a hospice is. To describe and compare programs across countries, it seems urgent to agree upon minimum criteria for developing a palliative care program at various levels of the health care system.

Therefore, EAPC is in the progress of establishing a new task force on “Centres of Excellence” in palliative care. The aim is to create a network of European countries at the university hospital level to establish common criteria of success and failure for developing a standard at all levels.

The challenges seem to be universal. These are first and foremost related to the total integration of palliative care in the general health care system both in the inpatient and outpatient sector and, as such, have huge policy implications. This includes education and specialist training at basic and advanced levels through universities and medical associations and a multidisciplinary approach. Furthermore, special national and EU research programs in palliative care are needed to take the next step towards EBM in palliation. Such programs should work toward defining relevant areas to obtain universal guidelines for treatment and delivery of care and to implement EBM. Striving for these goals is by no means in conflict with compassion—both are the cornerstones in the professional encounter with patients.

**PALLIATIVE CARE IN SITUATIONS OF CONFLICT**

Nathan Cherny and Ora Rosengarten

We used to wonder where war lived, what it was that made it so vile. And now we realize that we know where it lives, that it is inside ourselves.

Instead of killing and dying in order to produce the being that we are not, we have to live and let live in order to create what we are.

Those who lack the courage will always find a philosophy to justify it.

—Albert Camus

Situations of political conflict are characterized by enmity and potential for, or actual, violence. Conflict of this ilk may be manifested as outright war, a cycle of terror and reprisals, or a grumbling enmity between religious, national, ethnic, or cultural groups.

Incurable, life-threatening illness is endemic, and it often occurs in places of conflict. In these circumstances, care delivery is often compromised or complicated. Situations of conflict occur in many places in the world and, at any time, a substantial proportion of the world population is involved in conflict of one sort or other. Conflicts, such as war or terror, traumatize the involved populations. Bereavement, fear, anxiety and depression become commonplace. Persistent conflicts may generate feelings of hopelessness and helplessness.

These observations are derived from our experience in working with Palestinian and Israeli patients in a Jewish hospital in Jerusalem over the past several years.

**Our Context**

Jerusalem is a city that has existed in a situation of conflict over the past 100 years. Historically, this has been the ancient capital of the Jewish people, and currently it is the capital of the modern state of Israel. Jerusalem, however, is also claimed by the Palestinian Arab population as their capital. Indeed, Palestinians and Jews have been in conflict over the destiny of this small strip of land between the Mediterranean and the Jordan river...
since the inception of the plan to reestablish a Jewish state in the area.

Attempts to achieve some form of rapprochement between the Jewish and Palestinian peoples have been intensified during the past 15 years. The breakdown of negotiations in 2000 was accompanied by a violent Palestinian uprising, characterized by a wave of terror against Israeli citizens, with subsequent restrictions on Palestinian movements and reprisals against terror organizations and their supporters. Thousands of people have been killed on both sides.1,2

In the midst of this, The Cancer Pain and Palliative Medicine Service, in the department of Oncology at Shaare Zedek Medical Center, has provided palliative care for both Israeli and Jewish patients. Shaare Zedek Medical Center is a Jewish general hospital that serves the entire population of Jerusalem. Reflecting the demographics of the city, 20% of the population are Palestinian Arabs, most of whom are Moslems.

The Cancer Pain and Palliative Medicine service is an integral part of the oncology service, based in the Oncology day hospital. The service consists of two physicians, a palliative care nurse coordinator, an education and research coordinator, three social workers (Hebrew, Arabic, Russian), a chaplain, and a liaison psychiatrist and psychologist. The service provides ambulatory and inpatient care. Community care is provided in cooperation with a number of home hospice services. Although most of the clinicians are Jewish, both the Arabic-speaking social worker and thoracic surgeon (who works very closely with the service) are Palestinian.

Uniting and Dividing Experiences

Peoples on different sides of a political conflict of this ilk share a common traumatized existence.3 Both sides suffer from risk of violent death or injury; both sides are vexed by injustices wrought by the other. Two peoples with different readings of history and different cultures share a common home, a common homeland, and often common cities, neighborhoods and health care services.4

Illness is a unifying experience. The experiences of physical and psychological distress and fear of deterioration or death are universal. Similarly, the desire to care for the ill and to alleviate suffering is fundamentally universal. Indeed, even in the situation of awful conflict, health care can provide opportunities to bridge between communities and peoples.

Nurses have a special role to play in this situation. Given the greater opportunity for intimate contact and often, greater time for dialogue and compassionate care, their role is critical. This is true both in regards to care delivery and also for the critical role of developing bonds of trust. Communication is critical to the success of this endeavor, and this will often require the use of a translator to ensure that the patient is understood and that nurses understand the care provider.

Barriers to Care in Situations of Conflict

Infrastructural Barriers

Conflicts commonly disrupt the flow of persons (patients and health care providers), the availability of care, and the delivery of health care. Often patients are unable to get to the needed health care, and health care providers may be hampered in their ability to get to their patients. Physical resources may be limited by diversion of resources for other purposes, lack of free movement of goods, or use of limited health care resources by the combatants or victims. In times of war or conflicts, medications, sterile dressings, hospital beds, and health care providers may be in short supply. Often, the cost of medications may be inflated due to the collapse of health insurance arrangements or shortage.

Bias

Both patients and health care providers may be affected by bias against persons on the other side of the conflict barrier. This bias may be generated by resentment, fear, cultural misunderstanding, or demonization. Bias may hinder patients from seeking health care that might involve contact with health care providers or other patients from the other side of the conflict divide. Similarly, bias may influence health care providers in their attitudes or in delivery of care to persons on the other side of the divide. This can be as mild as personal distaste or as severe as overt hostile neglect or sabotage of treatment.

Distrust and Enmity

Neither patients nor health care providers are protected from the political and social environment. Both parties may carry and project distrust and/or enmity that may be manifest in the caregiver/patient interaction. Distrust and/or enmity can interfere with all aspects of care delivery. Distrust and/or enmity may also affect other relationships: patients sharing the same waiting room or adjacent hospital beds, health care providers from different sides of the conflict, or patient’s family members’ relationships with the health care providers.

Safety

Death or injury to health care providers is, sadly, common in war and conflict. Beneficently minded health care providers often feel naively protected by the nature of the humanitarian work that they undertake. The enmity of conflict is often such that it is stronger than any compunction about the killing of carers.5
Narrative: “I almost killed a patient today”

Monday night; 11 PM. I almost killed a patient with methadone today. She was (and thankfully still is) a 68-year-old lady who came to see me from Natanya. She has a huge inoperable cancer deep in her abdomen, and even with high doses of morphine, her pain hadn’t been adequately relieved.

Under close supervision, I gave her two doses of methadone. Over the next 2 hours, her pain subsided. She was able to get up and walk about. She seemed to have good relief without excessive drowsiness, confusion, or sleepiness.

Methadone is not widely available and, in Jerusalem, there is only one pharmacy that carries it. At 3:15 this afternoon, I wrote out a prescription and sent this lady and her husband to buy the methadone before they headed back to Natanya. To avoid parking problems, they went to the pharmacy by cab.

The pharmacy is in the middle of town... on Jaffa road near Zion Square. Half an hour later, I was called to the emergency room. A terrorist had shot some 30 people in the center of town... exactly outside the pharmacy. I was quietly panicked. They didn’t arrive in our emergency room. I checked with the emergency coordination center. They weren’t on any of the emergency room lists. That meant that they were either alive and well or, possibly, dead but unidentified.

It was a very long hour until they returned to the hospital to ask where else they could possibly get the methadone. The shooting had broken out as they approached the area, and their cab driver was diverted.

Few things scare physicians more, and particularly physicians relieving pain with opioids, than almost killing a patient with a medication intended to help. I am an expert in the side effects of methadone, but this would have been a new side effect for me. These are strange and evil times.

Abuse

In some instances, health care resources are abused to facilitate violence. The harboring of combatants or weapons in hospitals or clinics and the ferrying of arms or combatants in ambulances or disguised as doctors, medics, or nurses undermines the assumption of benevolence. To be respected, it is essential that the credibility of the beneficence of health care providers be maintained. Without the assumption of benevolence, ambulances, health care providers, or even patients may be submitted to justifiable suspicion, which may cause delays in genuine care delivery due to security concerns and suspicion of potentially hostile intentions.

Why Provide Care in Conflict?

The ancient Rabbi Hillel stated succinctly, “If I don’t look after my interests, then who will; but, if I look after my interests only, then what am I?”

Medicine is a fusion of humanity, science, and compassion. Humanity and compassion dictate that the suffering of illness must be addressed, and, when possible, relieved. This holds true for all who suffer, be they friends or foes. One need not love a foe, but their suffering can be acknowledged and should be relieved when possible. Through this process, new opportunities for understanding and for mitigating enmity can be developed.

Depersonalization and dehumanization of the enemy are common processes in conflict. Often members of the “enemy” are demonized such that they are perceived as fundamentally hostile, evil, or unworthy. These processes of depersonalization, dehumanization, and demonization are reinforced by lack of intimate contact between peoples. Perceived or real issues of fear, risk of harm, distrust, and enmity limit social contacts. All of these processes make the possibility of cooperation or conflict resolution more difficult.

Medicine has the potential to be a positive agent of change. Provision of care across lines of enmity creates the potential to reverse some of these processes. Given that suffering at the end of life is universal, there is a special opportunity for palliative care clinicians working in regions of conflict. While end-of-life care is so often ignored or neglected, palliative care emphasizes humanity and respect for human dignity in a very special way. This focus on humanity stands in stark conflict to the disregard for the value of human life that is so much part of war and terror. Through the delivery of care, there is a potential to break barriers of suspicion and hatred and to reverse the processes of depersonalization, dehumanization, and demonization.

CASE STUDY

Mr. A, Husband of a Patient with Metastatic Colon Cancer

Mr. A was a 40-year-old husband of a young Palestinian woman with metastatic colon cancer. Together they had four children and lived in East Jerusalem. In September 2000, Mr. A had been at the site of a violent clash between Palestinian protesters and the Israeli armed services. The young man who stood beside him was shot and killed, and he carried the body away from the battle scene.

When Mr. A initially came with his wife to an Israeli hospital, he was full of anger at Israelis and Jews, and he had little reservation about hiding his hostility. The treating oncologist was an orthodox Jewish Israeli, Dr. S. They communicated with the help of a Palestinian social worker.

For 2 years, Dr. S cared for this young family. Mrs. A underwent several lines of chemotherapy; some successful, others less so. When she developed a bowel obstruction, Dr. S arranged for a diverting colostomy and supported the family through the ordeal. The treating nurses would hold her...
hands, stroke her hair, and extended the same care and support that they would to any other patient.

Slowly, enmity faded and Mr. A, his wife, and family became part of the routine in the oncology day hospital. As her illness progressed, she became increasingly dependent on help from the palliative care nurse. Because the family lived in an area that had become increasingly unsafe for Israelis, and in the absence of a Palestinian home care program, we had to make do with telephone support and hospital-based ambulatory care.

Mrs. A ultimately developed a severe pain problem with lumbosacral plexopathy. She was admitted for pain stabilization. She did not achieve adequate relief with PCA morphine, and she was switched to methadone, which provided reasonable relief. It became clear, however, that she would not be able to return home, and she died in the oncology/palliative care ward, surrounded by her family and friends and her mainly Israeli doctors and nurses.

A week after her death, her husband returned with his four children with gifts and thanks for the staff. To Dr. S he said, “You are now my brother.”

Facilitating Care Delivery Across Lines of Enmity

Advertise Availability

Unless it is known that care is available irrespective of conflict, many potential patients may not seek help. Advertising can be in the form of letters to doctors, commercial advertisements, or via the print or video media.9

Demilitarize Hospitals and Clinics

It is absolutely unacceptable for hospitals to be militarized by any party in the conflict. Hospitals must be respected neutral territory. When this principle is not adhered to, those in need of help may be too afraid to seek care. The abuse of hospitals either as bases for attack or as asylum for health combatants undermines impartiality and potentially invites incursion or conflict.

Ensure Care Regardless of Ability to Pay

Health care provision costs money, and, unless supported by charity, costs must be covered to ensure ongoing ability to provide care. Emergency care should be available to all who present need, irrespective of ability to pay. For patients without insurance or financial resources, providing ongoing care can present logistic challenges. Several options are possible: provision of care at cost, arranging for care to be provided by health care services across the divide of conflict, or providing subsidized or charitable care. Arranging care at lesser expense to the patient across the lines of conflict requires the development and maintenance of lines of communications with health care practitioners on the other side of the conflict. In our experience, even in the setting of political animosity and differences, this sort of humanitarian cooperation has been possible and positive.

Ensure Physical Access

Patients, their caregivers, and family members may need specific permits to enable them to reach health care facilities across lines of enmity. Members of the health care team are often able to liaise directly with the civic or military authorities to facilitate the granting of permits. In doing so, there is an element of responsibility insofar as the clinicians need to be adequately convinced that these permits will not be abused to ferry either arms or combatants. Since the authorities at checkpoints may sometimes be hostile to the patients or their families, it is helpful to provide patients with written testimony to the fact that they are seeking health care, with a specific contact name and telephone number for verification purposes.

Provide for Cost Containment

To protect the interests of the patient and the health care provider, the clinician has a duty of care to try to contain costs of care provision as far as possible. This concern reflects itself in clinical decision-making in regard to both diagnostic investigations and therapeutics. One needs to be aware of the cost of medications and the most effective formulations to provide ongoing care. Commonly available formulations of controlled-release opioids may be prohibitively expensive, and cheaper options, such as immediate-release morphine or methadone, may be preferred.

Use Liaison Where Possible to Ensure Safety

Often patients can get adequate care without enduring all of the logistic barriers involved in crossing lines of enmity. It is often useful to liaise with physicians across the lines of enmity to evaluate the availability of care and the limits of care resources. In suggesting to a patient that they not cross lines of enmity and that they seek care locally, one must first be sure that there is a real possibility of receiving adequate care. In so doing, it is appropriate to invite open lines of communication to address any medical issues that may arise.

CASE STUDY

Mrs. FW, a Patient with Metastatic Breast Cancer

Mrs. FW, a 60-year-old Palestinian woman from a small village just outside Jerusalem, presented to an Israeli hospital with metastatic breast cancer with liver and bone metastases. She received palliative antitumor therapies in two Israeli hospitals. She was regularly reviewed in the day hospital by the palliative care service, which managed her pain with transdermal fentanyl and oral morphine.

Her condition deteriorated just as the conflict in Jerusalem worsened. Because of excessive personal risk, home hospice
services were unable to attend her. The danger was under-
stood by the patient and her family, who not only accepted
this with sorry resolve, but who actively discouraged staff
from placing themselves at risk.

Contact was made with a local doctor and nurse, and with
the support and instruction of the palliative care service, they
undertook a program of home care. When she was unable to
take oral medication, a PCA pump was provided and serviced
by the local medical team, with daily telephone support from
the palliative care service. This arrangement was successfully
maintained until the patient’s death at home.

Create a Bank of Returned Medications

Returned and unused medications are usually discarded or
destroyed. When there are potential patients who do not have
the resources to pay for medication, this is wasteful and inap-
propriate. Returned medications should be stored appropri-
ately and may be used in the care of patients who do not have
resources to pay for them. In our setting, we have successfully
done this with cytotoxics, analgesics and antiemetics, and
other potentially expensive medications.

Use Creative Improvisation

Often, normal care structures such as home hospice services
or day clinics will be unavailable or inaccessible. In such cases,
the available care resources need to be evaluated to explore the
possibility of some form of improvisation, which may be sub-
optimal, but at least fills a modicum of care needs. This may
involve a compromise on care plan; for example, when a PCA
could not be maintained at home because home care staff
could not safely visit, we switched the patient to methadone
suppositories, which were both cheap and effective. Often,
family members or sometimes friends and neighbors will need
to be trained to provide for care needs or even to do simple
procedures such as tube feeding, suction, and wound care.

International Organizations

Several international organizations have created special infra-
structures to assist in the provision of care in situations of
conflict. It is very helpful to know and to develop relationships
with those services and agencies active locally.

The World Health Organization (WHO)

Sponsored by the United Nations, this international organiz-
ation has widely accepted and acknowledged credibility that
usually crosses all lines of conflict. Indeed, WHO is mandated
by its Constitution (article 2) to “furnish appropriate technical
assistance and, in emergencies, the necessary aid upon the
request or acceptance of Governments.” In such situations,
I write these words, he lies in a three-bed room in Internal Medicine A at Shaare Zedek Medical Center (an Orthodox Jewish Hospital in West Jerusalem). He is weak and tired. Three of his sons were at his bedside when I bid him farewell tonight. As I left, I saw his eldest son prostrate and barefoot on his prayer mat, face to Mecca, deep in prayer.

Formerly a handsome man, with a strong resemblance to the late King Hussein of Jordan, Dr. Natshe is now withered and prematurely aged. The whites of his eyes are yellow tinged with an early jaundice from his now failing liver. His abdomen is distended with fluid and his legs are bloated by edema. His eyes are bright and his broad loving smile breaks through the misery, sadness, and fear of his current circumstances. Like many Palestinian men, he has smoked most of his adult life. Now the lung cancer that presented 9 months ago has erupted through the brief response to chemotherapy and threatens the function of his vital organs.

Today, I am Muhammed’s doctor, his oncologist, and palliative medicine physician. That was not always the case. I first encountered him as a colleague. He was a highly respected general practitioner in East Jerusalem. There, close to the spectacular hubbub of the Damascus Gate of the Old City of Jerusalem, he tended to a large practice. Patients he referred were among the first Palestinians whom I treated when first I arrived in Jerusalem some 7 years ago. He was a caring and involved family doctor. I was impressed and touched by his devotion: be it visiting his patients when they were admitted to our hospital, or caring, alongside the Home Hospice Service, for his patients who were approaching their deaths.

Dr. Natshe was a general practitioner by default. He had initially wanted to be a surgeon and had, indeed, started a surgical residency at Hadassah Hospital in early 1973. Shortly after it began, his residency was interrupted by the surprise attack of the Yom Kippur War. The Jewish world was shocked and outraged at the surprise attack. Most Palestinians supported the Egyptian/Syrian alliance. Dr. Natshe took leave from Hadassah during the war and, in the aftermath, he felt too embarrassed to return to his residency in surgery. After 3 years of general practice, he applied and was accepted back to Hadassah as a radiology resident. The medical world of Israel, the West Bank, and Jordan is small, and word of Dr. Natshe’s appointment quickly reached Amman. The Jordanian Medical Association dispatched a strongly worded letter of reprimand, intimating that it would be treasonous to work in an Israeli hospital. Thus, Muhammed returned to his general practice, where he worked until the toll of the lung cancer and the adverse effects of its treatment made it impossible to continue.

Faith and pragmatism: Dr. Natshe’s eyes twinkle with enthusiasm as he explains his love of Islam and the word of The Prophet. He is a deeply religious man and, in the encroaching shadow of death, his faith in God’s ultimate beneficence underscores his inner strength and courageous coping. His sons are dapper, deferential, and attentive to their frail father. Even in his ill-fitting hospital pajamas, I can see his tired chest rise with pride at the sight of them. He tells me that he insisted that each of them learn a trade before entering tertiary education. He has successfully assured them of short- and long-term economic opportunity. His eldest son, a part-time hairdresser, studies computer engineering at an Israeli Technical School; the second, a part-time truck driver, studies industrial chemistry at the Hebrew University. The boys speak to me in Hebrew and English. He tells them that they will need to look after their mother, as he will soon be gone.

Tomorrow, I plan to discharge Dr. Natshe back to his home in East Jerusalem. After 3 days in the hospital, his pain and vomiting are now controlled. He is very weak. I anticipate that in a week I will need to again drain his abdomen of the reaccumulating fluids that painfully distend his abdomen and compress his viscera. By then, he will probably be too weak to return to the hospital, so I will attend to him at home.

Dr. Muhammed Natshe, Palestinian physician, man of Islam, man of God, father and husband, is my colleague, my patient, and my friend. I will care for him and his family with all of the skill and devotion that I can muster. I have promised him my commitment and my service as long as it is needed. Sadly, that won’t be long.

That I am a Jew, that I am Israeli, that our peoples are in conflict in an awful time of violence and hatred are irrelevant to the humanity that binds us. I will miss him when he’s gone.

Behind the headlines, behind the shocking and awful images of violence, death, cruelty and humiliation . . . small acts of caring, cooperation, and love play themselves out . . . daily. This is another reality of the Intifada. Gladly, this is part of my reality; my source of hope and strength.

Conclusions

War and conflict are among the major challenges to man’s humanity. The provision of palliative care in times and places of conflict is fraught with personal and infrastructural difficulty. In meeting these challenges, medicine and health care providers have the potential to be positive agents of change. The challenges are great but the potential rewards even greater.

PALLIATIVE CARE IN SOUTH AMERICA

Marta H. Junin

South America occupies a territorial area of 18,678,047 square kilometers and is populated by 345 million inhabitants distributed in 12 countries: Argentina, Bolivia, Brazil, Chile, Colombia, Ecuador, Guyana, Paraguay, Peru, Suriname, Uruguay, and Venezuela (Figure 66–8). There are different geographical regions with distinctive characteristics: the ocean coasts, the tallest mountain chain of the Andes, the long rivers such as the Amazon, large forests, wild jungles, prairies, lakes, deserts such as the Puna of Atacama, and islands, each one with its own cultural characteristics.

South America offers one of the more complex demographic realities from the point of view of ethnic composition, history of conquests, colonialism, and immigration. The indigenous populations over many generations have accumulated their own scientific knowledge, traditions, and holistic approaches to their lands, natural resources, and the environment. These populations are extremely vulnerable in today’s society.

The official language in the majority of South American countries is Spanish, with Portuguese spoken primarily in Brazil. Indigenous groups also have their own languages, for example, Mapuche, Quechua, Aymara, Guarani, and Yámana. These are considered a secondary language in some countries. The South American population is mainly a mixture of races, descendants of European conquerors and American aborigines. There is a constant migration of people from areas of extreme poverty to more developed urban regions. This has resulted in problematic, uncontrolled urban growth. The large cities contain 50% of the total population. At the same time, however, there has been a large population emigration, mainly to the United States and Spain.

Political and Social-Economic Situation

The government systems, after long periods of authoritarian regimes, military dictatorships, and political instability, are mainly democratic, with constitutional republics and presidents. The establishment of democratic regimes and greater societal participation in the political arena are considered important achievements in the last 2 decades. However, the return to democracy hasn’t yet been sufficient to reduce the social and economic inequities that threaten a country’s stability, social integration, and ability for sound government. Ways to strengthen democratic principles and practices present ongoing challenges. This is especially so in situations of economic poverty, uncertainty, and struggles between peace and violence. All of these issues affect a population’s health.

The conditions and levels of social and economic development in South America are generally heterogeneous. However, these factors significantly mold the health and welfare of the population. The economic and social transformations experienced by South American countries in the 20th century have been characterized by governmental efforts to reduce inflation,
increase investment, and privatize companies, all in response to recommendations of the International Monetary System.

State reform, with its emphasis on efficacy and modernization, underscores the important role of government and civil society in economic and social development. A population’s health is defined by its economic situation.1 A country’s social and economic crisis presents an opportunity to promote programs with quality, efficacy, and equal access. Palliative care programs are one example.

### The Health Systems

South America is a region with large income differences. At the beginning of the 21st century, large variations in life conditions were noted between countries and within countries. Differences in educational levels, technical knowledge, income, health resources and organization, health service accessibility, and other social characteristics that determined a population’s state of health were also noted.

All South American countries are considered “in development” by the World Health Organization (WHO). In addition, the population is aging, with an average life expectancy of 70 years. Increasing health care needs come with age. Services such as disease prevention, recuperation, rehabilitation, and palliative care are especially important for older people. In this age group, deaths from cardiovascular diseases are the most frequent, followed by cancer.1 For individuals suffering from advanced cancer, AIDS, cardiovascular disease, or irreversible trauma, access to palliative care is extremely important.

Resources for cancer control are not uniformly distributed in the world. More than 95% of the total resources are located in developed countries and, not surprisingly, less than 5% in the developing countries (Table 66–8).2 Likewise, there are differences between developed and developing countries in relation to cancer diagnosis, death from cancer, and availability of treatment resources (Table 66–9).3 Unfortunately, this means that most of the people who need palliative care live in those countries with the least resources.

In South America, there are different health systems. These are organized around three main providers that cover different percentages of the population in each country:

- The public system, with national, provincial and municipal-communal jurisdiction, supplies free clinical care through primary health centers in the community and general-specialist public hospitals for inpatients and outpatients. In some countries, the national health system provides assistance to the whole population without distinctions of race, economic situation, or religion.

- The insurance social system for working people is administered by trade unions. Employers and employees each pay a fixed fee. The cost of medical care and medicines in varying proportions are covered. Differences between the fixed fee and the actual treatment fee are paid by the patient.

- The private sector is for individuals with a good income. In this system, patients meet the total cost of their care. In some countries all non-working people are referred to this sector, with the risk that some will not be able to access health care because of lack of income. In general this health system assists a small percentage of the population.1

### Overview of the Health Context and WHO Palliative Care Programs

The neoplastic diseases are the second leading cause of death in all countries of the region. Despite this figure, few resources are spent on cancer prevention measures. It is estimated that the total number of cancer cases will increase by 34% each decade. If current trends continue, by 2020 approximately one million persons in South America will need palliative care and relief from cancer pain.4

In response to these statistics, WHO and the Pan American Health Organization (PAHO) designated palliative care as a priority in the Cancer Relief Program. They adopted measures for the development of palliative care programs in South America that were responsive to regional needs and specific problems. Attention was paid to the different income levels, disease presentations, technical expertise, resources allocated to health organizations, and access to health services in each country.5

The goals of the programs are:

- That palliative care is integrated into the medical assistance models.
- That availability of resources for palliative care are evaluated.

• That opioid drugs are available for pain relief.
• That health professionals are qualified and trained.

In 2004, through the support of PAHO, there were seven model projects in palliative care. South American countries involved included Argentina, Ecuador, Chile, Colombia, and Venezuela.

With a similar focus, WHO based its approach to improving palliative care in this region on three components: government policies, opioid availability, and professional education.

**Government Policy**

The WHO National Program against cancer identified palliative care as a priority for national cancer programs. WHO requested that governments revise their policies as to how they allocate resources in cancer treatment. Most patients in developing countries with cancer present for treatment with advanced disease. Nonetheless, many developing countries assign a large proportion of their cancer resources to sophisticated treatments that have a low impact on the majority of the population. WHO recommendations are that more than half of these health care resources be directed towards palliative care, which will benefit a much greater proportion of the population. In addition, WHO suggests using the information in the program to open up discussions with regulators and institutions interested in establishing or extending palliative care services. Although palliative care professionals are aware that this approach to care offers the most holistic treatment for both patients and their families, some health authorities still think that palliative care is "second-rate" medicine, and they prefer to invest their money in newer and more expensive technology. People involved in palliative care have some responsibility for this because they have not demonstrated to the health authorities the benefit and cost-effectiveness of this work.

Despite the strong endorsement and encouragement from WHO that all countries examine their system of national cancer control programs (and if one does not exist, develop one), many countries in South America do not have such programs. As stated by WHO, "A national cancer control program is a public health program designed to reduce cancer incidence and mortality and improve quality of life of cancer patients, through the systematic and equitable implementation of evidence-based strategies for prevention, early detection, diagnosis, treatment and palliation, making the best use of available resources." Pain relief and palliative care can improve the quality of life of patients and their families. With careful planning, implementation, monitoring, and evaluation, the establishment of national cancer control programs offers the most rational means of achieving a substantial degree of cancer control, even where resources are severely limited. The establishment of a national cancer control program is recommended wherever the burden of the disease is significant. There is a rising trend of cancer risk factors, and there is a need to make the most efficient use of limited resources.

**Availability of and Access to Opioid Analgesics**

In palliative care, one of the basic principles is the relief of pain with the use of the WHO Analgesic Ladder and the use of opioids. All the South American countries have adopted the WHO Guidelines. However, changes in legislation and regulations are urgently needed to allow adequate access to opioids.

There are still some difficulties with the treatment of cancer pain in this region. The health policy does not endorse opioid analgesics. As a result, many cancer patients still die with their pain uncontrolled. Additionally, patients and their families retain many taboos related to the use of these opioids, necessitating that the palliative care teams spend much time educating the family about the use of opioids such as morphine.

There are many myths regarding palliative care, and still many health care professionals who do not know how to adequately assess and treat pain. The misplaced fear of respiratory depression or hastening death through the use of opioids remains common. Opioid phobia among regulators is illustrated through their concern that making opioids available for therapeutic use would increase the illicit drug market.

Although opioids can be easily found in the capital cities, prescriptions for controlled substances require many copies. Ready availability of opioids is not a reality for the inner-country people. These people must come to the capital city to get opioid medications for pain relief. The most frequently used opioid for pain is morphine (ampules, syrup, pills) because of its availability, effectiveness, and cost.

Morphine is available in all South American countries but the law and regulations aren’t conducive to opioid use. Morphine consumption by terminally ill patients is still low in many South American countries, mainly because of insufficient medical prescription and morphine myths among health professionals and the general population. This suggests that pressure should be exerted on the government to support the teaching of palliative care in public education programs.

In many situations, opioids are available but the high cost limits their availability to only those who can pay. A comparative study among some of world’s countries indicates that opioid costs in developing countries is higher than those in developed nations (medians U.S. $112 in South America vs. U.S. $53 in the United States), and in percentage in relation to monthly income per capita (medians S.A. 31% vs. U.S. 3%). In some South American countries such as Argentina, the high cost of opioid therapy can be more than 200% of the average monthly income. This problem reflects politics where expensive and sophisticated opioid preparations such as ampules and controlled-release oral morphine are available, whereas cheaper preparations such as immediate-release oral morphine tablets or elixir are not available.

Many countries, in their eagerness to prevent opioid misuse, have adopted laws and regulations resulting in restrictions that have affected the medical use of opioids; for example, imposing limits on the doses and days of treatment allowed per patient. A comparative study of a group of Latin American
countries indicated that none abided by the principles of drug availability. Indeed, some of them have included articles to forbid the use of control drugs or the administration of opioids to minors; yet children develop painful cancers and will die of their cancer.9

For many years, the Pain and Policy Studies Group (PPSG), WHO Collaborating Center for Policy and Communications in Cancer Care, and University of Wisconsin in the United States, have given advice and technical support to PAHO and South American countries to find a solution to the problem of guaranteeing the availability of opioids analgesics for the whole population.10,11 Their guidelines offer tools to help governments and health workers identify barriers in laws and regulations that make access to the tools of palliative care (for example, opioids) impossible or difficult to obtain.

PPSG and PAHO have designed a workshop for governments, drugs regulators, and palliative care professionals. During this experience, the representatives of both groups identify specific problems of each country and find solutions.10 They have developed two workshops: in the Andean region—in Quito 2000—which includes Bolivia, Chile, Colombia, Ecuador, Peru, and Venezuela; for the South region MERCOSUR—South Common Market—including Argentina, Brazil, Paraguay, and Uruguay—in Montevideo, 2002. In both workshops, questionnaires indicated that in countries where communication between government representatives and health professionals was good, palliative care was more developed. Argentina, Colombia, Chile, and Brazil were examples where there was good communication and there were fewer problems with opioid availability.12–14

South America uses less than 1% of the world’s morphine consumed for medical purposes.15 Some of the reasons are restrictions or excessive bureaucracy in the importation process of drugs, which increase the final cost of the product; legislation and restrictive control that impose maximum limits in the daily doses; delivery systems that are insufficient to make availability of these drugs uncomplicated in the rural area; health staff that are uneducated in the use of opioids for the relief of pain; concerns about addiction; and reticence to prescribe or store opioid drugs because of concern about legal liability if the drugs are stolen. In addition, there is a lack of authorized pharmacists for the preparation and delivery of opioid drugs. This was the description and consensus of the participants in both the Quito and Montevideo Workshops.12,13

Strategies were developed by PPSG of Wisconsin for implementation of the WHO Guidelines16 to eliminate those barriers that hinder the provision of opioid analgesics to patients in South America:

• Organization of a symposium similar to Quito and Montevideo in all the countries. In addition, to organize a meeting with representatives of several professional groups working in pain relief, oncology, and palliative care, along with control and regulation drug authorities. The purpose of the meeting would be to discuss and develop national policies to improve opioid availability for the relief of pain.
• To set up a committee with representatives from pain and palliative care organizations to study the WHO Guidelines in relation to their own situation in each country. They would collaborate with the PAHO regional officers in developing a proposal for national policy reform in relation to these guidelines.
• Diffusion via the media and by scientific publications of the WHO Guidelines through government and nongovernment organizations (NGOs).

There are still many problems regarding adequate availability and access to potent analgesics in South American countries. This region is still challenged by poverty, lack of education and training, and barriers at the regulatory, legal, and administrative levels. Governments are concerned with such problems as lack of infrastructure, difficulty gaining access to care centers, and improving control of acute infections and vaccinations, and many have yet to place opioid availability on their priority list.

Because improving access to opioids is an international effort, we are all affected to some degree by the decisions and actions taken by others. We need to become aware that opioid availability is not just a local issue, but, rather, one with no borders. All stakeholders in this process, including patients, professionals, multilateral organizations, the pharmaceutical industry, policy makers, and health care professionals, need to be included in the development of strategies to improve this situation.8

Education

There are educational needs for the general public, health professionals, legislators, and regulators. In many South American countries, there is lack of community information and education programs about palliative care and insufficient and nonsystematic education activities for health professionals. Examples are nonaccreditation of services and noncertification of professionals in palliative care.15

In some South American countries, there are regional and local initiatives for professional palliative care education, however, standards in training are lacking. Training is generally done by the professional, on her/his own initiative, and it is generally theoretical, with few opportunities for clinical practice. At the moment, a fundamental change is occurring in palliative care education opportunities. A variety of training systems have been implemented, including university or nonuniversity courses, single discipline or interdisciplinary methodology, distance-education systems, or activities with a marked clinical emphasis. These diverse types of learning methods facilitate the professional’s ability to acquire or complete his or her pain and palliative care education. In addition, topics on pain treatment, palliative care, and
mournings are being included at the undergraduate level in medicine, social work, and psychology, and in nursing schools and universities. In some university hospitals, access to the palliative care approach is possible for all health care students. There are lectures or modules on palliative care available to all students in the last year of their training. This surely is an important way to improve patients’ access to palliative care in the future. At a postgraduate level, activities are carried out at the main educational centers. The current focus on palliative care in the educational system gives hope for real change in the future.

One of the main obstacles to palliative care team members’ training is the high cost of medical and nursing education. Nevertheless, in recent years, several Latin American programs have generated free education resources for professionals training in symptom control and palliative care, WHO Guidelines Spanish translation, and medical and nursing scholarships. Financial support is given mainly by NGOs to individuals who are willing to travel abroad for training in palliative care and for leaders to attend major scientific conferences.

The nurse's education in pain relief and palliative care is one of the basic principles in the priority ladder on pain control by WHO. This is taken into account in many South American countries by the coordinators of nursing training programs to include these issues in undergraduate, service education and postgraduate levels.

The Historical Perspective and Current Status of Palliative Care

During the early 1980s, due to the influence of the Hospice Movement and WHO’s Cancer Pain Program, modern palliative care concepts began to spread in an organized manner across South America. The development was unlike that in Europe or North America, because social, cultural, and economic characteristics made it difficult to follow those models exactly.

The historical context of palliative care was similar in many South American countries, with a lack of support from governments and health authorities. The palliative care movement began with small, motivated groups of health professionals working with terminally ill patients in public and private institutions. This movement coincided in some countries with the beginnings of democracy and ending of dictatorships and years of violence. Progress was slow, largely due to lack of financial support. However, once links were established with European and North American centers or universities, physicians and nurse leaders gained an opportunity to receive palliative care experience in more developed services and programs outside of South America.

Eventually, palliative care units were established in public hospitals, with programs that provide hospital-based care to terminally ill patients. In some cases, close and collaborative relationships were built between the oncology departments and palliative care services. During these early stages, support from the international palliative care community and NGOs was invaluable. Advice on educational, philosophical, and organizational skills was sought from experienced palliative care practitioners in the United Kingdom and the United States.

The experience of Chile in the 1990s shows what can be achieved with important support from national health administrators. It began with the development of several interdisciplinary palliative care teams organized as “local programs” in their respective health centers. Later, each one of these teams was consolidated as a “motor team”—the driving force of the future national program. The aim was to create awareness in the health sector about palliative care. Up until this time, there was little awareness. These pioneer groups became the National Committee. The committee reviewed the international literature and similar programs in other countries and organized standards. A high level of interest and financial support from the Health Ministry regarding “Pain Relief and Palliative Care National Programs” was officially recognized for cancer patients. Primary health services and public hospitals introduced a consulting team for inpatients and for patients cared for in the ambulatory setting. Today these centers cover 70% of the Chilean territory.

Ministries of Health need to invite health institutions to form an advisory committee to draft national quality standards for palliative care and to create a national network. The message is: “If you have a poor community, then you must introduce palliative care programs to provide the majority of the population access to this health care.” In some countries, there are national laws that guarantee access to palliative care throughout the health system, but these laws have little real impact on practice.

In 1991, the First Palliative Care Latin American Meeting took place in Argentina. The participants recommended that national associations of palliative care be created. Today almost all of the South American countries have their own scientific Palliative Care Association. Prior to the formation of these organizations, palliative care teams could only count on support from the Anesthesiology Association for the Study of Pain, oncology societies, and the experience of neighboring countries. The Latin American Association of Palliative Care was created in 2000. The last Congress took place in Montevideo, Uruguay in April 2004, with the participation of professionals from all Latin American countries.

The Palliative Care Teams

The Palliative Care South America teams are made up of doctors from different specialties, registered and practical nurses, pharmacists, psychologists, social workers, spiritual or religious representatives, and volunteers. The coordinator is generally a doctor. The number of team members varies according to availability of resources. The teams work in a similar way to other teams throughout the world, but in many cases without enough resources and government support. The team’s activities
are symptom control, psychosocial support to the patient and the family, bereavement support, education and training, and clinical research. The team members are available via a 24-hour telephone-contact service.

Different models have been developed including general hospital units, consulting teams for inpatients and patients in the ambulatory setting, and, when possible, home care. Some teams do not see patients at home because of lack of government funding. There is already a movement to provide such care with the support of NGOs. However, some palliative care services have only informal support from the national health system, because palliative care is not recognized as a specialty and is still considered to be unimportant. Plans for future development include improvement of home care public programs specific for palliative care from the hospitals. Some teams that provide private care already exist, but there are few health institutions similar to a hospice. In some places, there are charitable, nongovernmental associations designed to provide clinical care to hospital patients and outpatients. These only exist in large institutions in the main cities of some countries, but not in rural areas. In general, palliative care teams do not exist in rural communities.

The frequency of use of a specialized palliative care team varies, and is dependent on recognition by the patient’s primary physician of the need for input from such a team. In some cases, general doctors are struggling to address a patient’s concerns regarding end-of-life care, but the physician in charge of the patient has primary influence on that patient's care.

In many hospitals in South America, the concept of teamwork is not evident. Professionals work more as individuals within a group, each with his or her own tasks and objectives. Doctors may fear losing their patients, as they would also lose the patients’ fees. Therefore, there is an element of understandable competition among colleagues. Conversely, the atmosphere among nurses is more passive. The doctors’ competition and the nurses’ passivity appear to block interprofessional communication, which, in turn, can affect patient care. The concept of interdisciplinary teamwork is poorly developed in most centers, and the nurse tends to have a low status. Encouraging communication between the two groups and the development of interdisciplinary palliative care training programs is important to enhance the understanding of the role of the other.

Today there are many registered teams, including pediatric teams, working in different parts of South America. Some areas have many teams, others few. There is an increasing interest by health professionals in improving knowledge in their respective regions and in creating new palliative care centers. The challenge is to work with the local community as well as governmental and other agencies.

The Nurse’s Role in Palliative Care Teams

The number of interdisciplinary teams working in palliative care is expanding in all regions of South America. Nursing interventions in outpatient, home care, and inpatient hospital settings are increasing day by day, and nurses have independent roles in this area. There are specific characteristics and substantial differences between the role of palliative care nursing and those in other medical specialties.

In all care settings, registered nurses working in palliative care assume key roles in the following areas: patient and family assessment; provision of direct care such as hygiene, comfort, wound dressings, and other treatment; management of distressing symptoms; monitoring the therapeutic effect and side effects of the opioid analgesics; administration of medicines and other procedure regimens; liaison with related services, particularly local doctors; referral and coordination of volunteers; provision of patient and family resources; professional and community education; and provision of bereavement support are all part of their role. One of the most important nursing tasks is family support, education, and training on various aspects of symptom management. Without appropriate education, care of the terminally ill patient by the family at home becomes impossible. The nurse supervises home care through visits or telephone support. In addition to these responsibilities, the nurse participates in multidisciplinary patient consultations, takes an active part in the assessment, diagnosis, treatment, and decision-making processes with the patient and family, and actively participates in the palliative care team meetings.

In many South American countries, working conditions are difficult. Hospital wards are overcrowded and understaffed, often with many patients per nurse. This situation causes a high level of stress. The nurse’s status is relatively low, and nursing is not a profession that many people enthusiastically pursue. There are few nurses working full-time in palliative care, and many work part-time. In addition, interprofessional communication is not on an equal level. Multidisciplinary–interdisciplinary workshops have been encouraged, and palliative care is one of the first disciplines in medicine–nursing to be taught in such a collaborative fashion. Nurses now have a voice in medical meetings, and they are beginning to be recognized for what they can offer, and not just as handmaids to doctors. Another innovation in nursing is the use of interactive teaching sessions rather than the traditional didactic methods common in unidisciplinary nursing and medical teaching.

Nurses working in rural areas believe there is significant work to be done to help them provide for the palliative needs of the community. Rural and remote communities are not homogeneous; they offer various challenges to health care delivery based on demographics, local culture, physical environment, and distance from health services. Rural nurses providing palliative care in the community suffer significant professional isolation. But interestingly, people living in these regions do not have the profound negative beliefs and thoughts about death and dying as seen in large cities. In some settings, particularly in remote areas, the nurse may be the sole health practitioner in a community, receiving telephone support from a doctor located some distance away. The challenge is to find sustainable models of palliative care provision in many of
models of excellence and innovative community projects

these communities without specialist services and technologi-

ical advances.

It is important to understand the different levels of nurse
training that exist in South American countries: those with a
doctoral or master’s degree in nursing, those with a college or
university degree, licensed nurses, and auxiliaries.17 There is a
lack of consistent inclusion of palliative care in undergraduate
curricula across the countries. In general, a discrete mod-
ule in the form of an elective is offered to a small group of
students. This situation is changing, as there are more and
more nursing colleges and universities that include palliative
care content in the curriculum at all levels of undergraduate
programs. Palliative care team staff are commonly involved in
the provision of theoretical and practice education to the stu-
dents, at their personal initiative.

The demand for palliative care education has increased.
There are education programs available to prepare nurses for
their role in some government institutions. These courses
range from 1 day to 50-/100-hour programs on different
aspects of palliative care. Nurses with experience and knowl-
dge set up palliative nursing inservice programs for their
unit and for nurses from surrounding hospitals. All of them
have benefited from the work in presentation and teaching
skills.

Access to postgraduate palliative care education is often a
product of geography, with more educational opportunities
in large urban centers than elsewhere. There is an increasing
emphasis on the provision of specialist courses via distance
education. In some cases, this is supported by information
technology such as teleconferencing and Internet delivery.
These approaches overcome some of the access issues. Cur-
rently there are no postregistration diplomas or master’s-
degree nursing programs in South American countries,
nor are such programs available to other health care profes-
sionals.

One recommendation is that postregistration continuing
education should be structured in such a way as to ensure the
development of nurses prepared for clinical nursing roles in
specialist areas. Also recommended is that links with higher-
education institutions be developed to accredit such courses
for nurses, and that all courses be subjected to a joint profes-
sional and academic validation and accreditation.17

In the area of palliative care nursing research, the aim is to
develop knowledge to sustain and to guide nursing practices.
However, health research in South America is primarily car-
rried out by medical doctors, with minimal nurses’ participa-
tion in these projects. The overall number of nurses involved
in research is very low. The reasons for this scant nursing
participation in research include inadequate training at an
undergraduate level on the principles of clinical research, the
need to work two or three jobs because of low wages, and the
limited number of grants available for nursing research.
However, some institutions have generated initiatives as
fellowships for nursing research, including participation in
presenting work guidelines, explaining patient informed
consent, gathering information personally or by phone,
entering statistical data for future analysis, and present-
ing and discussing results in quantitative and qualitative
research.17

Sociocultural, Religious, and Spiritual Issues
Influencing Palliative Care

In spite of South America’s cultural diversity, the predominant
religion is Catholicism. Most people have a deep faith, so the
spiritual aspect of care is very important to terminally ill
patients. A patient who realizes that he or she is dying may
lean heavily on religion, as does the family. As a result, most
patients prefer to spend their last days at home, surrounded by
relatives. In addition, the presence of a spiritual assistant at
the hour of death and confession to a Catholic priest may be very
important at this time. In South American cultural groups,
many patients think that illness is a punishment of God and
that only God can grant salvation, relief, and even healing.

Nurses have a hard humanistic role to carry out in accord-
cance with Catholic principles. They are the first and the last
contact when the patient consults at a health institution, and
they usually hear and are exposed to all the family problems,
worries, anxieties, feelings, and grief. Nurses recognize the need
for appropriate palliative care education to respond appropri-
tely to the patient’s religious needs.

Some people in rural areas have adopted a stoic attitude in
the face of painful experiences. In villages far away from large
cities there is also a strong influence of folk medicine, quack-
ery, and popular herbal alternative treatments not prescribed
by medical doctors. All of these beliefs and practices hinder
dying persons from accepting medical treatments such as pain
and symptom control.

In addition, both health care professionals and the general
public see morphine as synonymous with death. Its safe and
effective use needs to be seen to be believed and be under-
stood. To change popular myths about opioids, the palliative
associations need to offer professional health care educa-
tion and training in all regions of the countries. The educa-
tional role of nurses is crucial because they are especially
sensitive and aware of the importance of the relief of pain.

In South America’s multicultural environment, the lower
social status of most patients in relation to doctors makes it
difficult for them to communicate fears, needs, and queries,
and, as a result, almost impossible for them to understand the
implications of treatment. In most instances, there are nurses
acting in an advocacy-and-treatment translator’s role. Direct
and honest communication between patients and doctors is
rare. Constraints on the doctor’s time make meaningful expla-
nations difficult. In addition, the relatives may see the doctor
first and tell the doctor not to tell the patient about a diagno-
sis and prognosis. A “conspiracy of silence” isolates the patient
early on, denying the opportunity to attend to “unfinished
business,” and imprisons him or her in a lonely world of
silence and secrecy in which all treatment choices are denied.
The concept of the strong family support network in South America is currently under threat. It still exists, but the culture is changing. More women go out to work as opposed to working at home, and more families are becoming isolated from the larger family unit. The move away from the village to the cities continues as people search for work. There are reports of patients with advanced cancer being abandoned by their families because financial resources are so drained, or because family members cannot cope with their own terrible suffering and feeling of impotence at the sight of someone they love in uncontrollable pain.17

Sometimes relatives are not caregivers of terminally ill patients because patients are frequently sent to hospitals far away from their homes. This also means that family doctors are not involved in this type of care; rather, the main responsibility for terminal care remains on the hospital doctors and nurses where the patient has been admitted. Even though these doctors and nurses are improving their knowledge and skills in palliative care, the challenge is still great because most patients and families do not participate in the decision-making process.

When the hospital is near to the patient’s home, in keeping with the family structure and South American traditions, a relative is required to stay at the health center when the patient is admitted. The relatives are involved in the training program during this period. The training given is as follows: importance of cleanliness and hygiene at the personal and family level, wound care and dressing, how to feed the patient, pain treatment, use of morphine, patient’s medication including the patient’s timetable at home, and how to keep the patient occupied. The team staff are acutely aware of the patient’s needs and transmit this to the family.

Traditionally in South American countries people died at home, but the situation is changing. Because most of the patients who come to a palliative care service arrive from the rural areas of the country or from surrounding towns, they prefer to stay in the hospital. Acute care beds are used for palliative care, where some patients feel safer because of staff presence. They have added spiritual and psychological support from the palliative care team. Most of these patients do not have a home care service to ensure that they will be cared for in their homes.

There are regional differences in availability of home support. In some South American countries, palliative care can be provided in the home through national, provincial, and municipal programs, but community-based palliative care programs for the whole population are still a challenge in most countries. Although many patients would prefer to die at home, there are multiple reasons to explain why the majority of patients nowadays die in hospitals in these countries. These reasons include low educational level, lack of socioeconomic resources, fears harbored by relatives about the development of the disease and end of life, past bad experiences, lack of relatives, and difficulty in symptom control. An educational family program must be established with the aim of helping the family become aware of their importance and role in the care of the patient at home. Palliative care teams keep in touch with relatives by phone to offer help in case of unexpected home events. The availability and accessibility of comprehensive and coordinated home care services are pivotal in making death at home a realistic option.

Inpatient hospices are not yet the chosen place to die for most individuals. Two reasons contributing to this are the lack of such hospices and the stigma and fear sometimes associated with this type of institution in South American culture.

Ethical Issues Influencing End-of-Life Care

Because of cultural barriers existing in South American countries, most doctors have difficulty in communicating with patients regarding their cancer disease and terminal status. The doctor usually informs the family, but the relatives often desire to protect the patient from knowing the truth. The patient progressively loses his or her autonomy, and the family makes decisions without the patient’s explicit consent. Freedom of choice is compromised for patients due to:

- A patriarchal–protective presence of family members in medical decision-making
- A paternalistic attitude toward patient care on the part of physicians
- The strong influence exerted by the Catholic church on public debate
- A lack of communication skills among health care professionals

In recent years, increasing attention has been given to patient self-determination and autonomy, especially in decisions surrounding the end of life. The challenge of addressing South American attitudes to truth-telling within a multicultural society is experienced by some countries. “Truth with tenderness,” with patients determining how much they wish to know and who should have access to their information, is the goal of communication. Ideally, communication regarding goals of care should include discussions about the use of hydration, antibiotics, and artificial feeding, as well as the potential use of cardiopulmonary resuscitation. Palliative care has initiated a change from the long-established practice of not telling a patient his or her diagnosis to one that respects the patient’s right to know and facilitates open communication. The concept of patient autonomy is just starting to emerge in some South American countries.

In large cities, one of the problems confronting palliative care doctors is the high expectations of both professionals and the public regarding the preservation of life at all costs, especially when the dying person is in the intensive care unit (ICU). Health care technology is used indiscriminately, and patients with advanced cancer are often dying alone in ICUs, wired up to every possible machine and with no nurse in attendance. Outside the ward, the patient’s family, denied access to the bedside, wait for the inevitable. Both family and
Discussions about resuscitation or the benefit-versus-burden of admitting a patient to an ICU if chances for improvement are small or nonexistent are held infrequently in South American countries. Most patients have difficulty addressing these subjects, and few palliative care teams broach them. In addition, the use of living wills and other advance directives are still uncommon, and such documents do not carry much legal weight. Some palliative care teams, however, appear to be making inroads in addressing these issues.

Communicating diagnosis and prognosis to the patient, and recognition of the ethical responsibility of obtaining informed consent from the patient regarding treatment and other important decisions, appear to be occurring more frequently and to be approached with less discomfort. In recent years, interest in ethical issues at the end of life has increased. The need for ongoing discussion of ethical issues and for continuing education in palliative care and ethical dilemmas for physicians in training and nurses who provide end-of-life care is evident. Some nurses express feelings of guilt and unethical practice when asked by a doctor to sedate a patient, and some feel that they are being asked to practice euthanasia by following medical orders.

In an attempt to change this situation, the palliative care team must run workshops and support groups for families and patients, where they can speak about subjects such as feelings, the myths of morphine, doubts and fears about death, and any worries that the family or the patient have. All those involved in end-of-life care, including patients and families, also need to understand the difference between palliative sedation for intractable symptoms at end of life and physician-assisted suicide or euthanasia.

Overall, in South American countries, there is a growing consensus that end-of-life issues must be discussed more fully, including the country’s position regarding euthanasia and physician-assisted suicide.19

In addition, there is consensus that access to high-quality palliative care must be promoted through government policies that provide resources for a competent multidisciplinary palliative care workforce across South America.20 We have come a long way, but we still have a long way to go.

---

**Palliative Care in South America: Weaknesses and Strengths**

**Weaknesses**

**Government Policy:**
- Lack of recognition of palliative care needs in the national and regional health programs
- Difficulties in all the health sectors: public, private, and social-security, with insufficient fulfillment of palliative care requests
- Lack of institutional financial support because palliative care programs are not a priority
- Failure to uphold the WHO recommendations in practice regarding cancer relief and palliative care

**Availability of and Access to Opioids Analgesics:**
- Lack of suitable legislation; bureaucracy; passivity and inequality regarding the prescription; availability and allocation of opioids
- Excessive cost, inefficiency in the management and administration of analgesic drug supplies
- Common popular and professionals’ attitudes regarding morphine prescription and myths
- Economic difficulties of the poor population to pay for the treatment, and lack of government analgesic provision

**Education:**
- Absence of informative and educative programs about palliative care benefits for the community
- No systematic training activities for the health professionals before and after graduation
- Little and expensive palliative care advance education
- No master, specialized degree, or diploma levels in palliative care education
- Misconceptions about the use of morphine and other strong opioids by health professionals
- Difficulty accessing palliative care education for health professionals in rural areas
- Lack of professional training about how to listen and how to communicate bad news
- Limited academic connection among palliative care professionals

**The Palliative Care Team:**
- Absence of palliative care standards, professional certification, and systematic service accreditation
- Lack of an operational network of palliative care providers among different cities, regions, and countries
- Unequal interprofessional communication
- Lack of professionals trained in palliative care
- Insufficient financial support of palliative care teams
- Low salaries, and sometimes none, for palliative care professionals
- Difficulties in guaranteeing volunteer work and charitable funding
- Few researcher opportunities due to a low priority given to research in the culture, and a lack of time, rigorousness in the scientific methodology, resources, and industry support
The Nurse's Role in the Palliative Care Team:
- Medical community unaware of the importance of the nurse’s role in the interdisciplinary palliative care team and as agent of change in society
- Widespread acceptance in the medical community of the paternalistic attitude of the physicians
- Palliative care training needs not considered in order to achieve safe practices
- Many eligible patients, yet few nurses with training in palliative care
- Low nurse status in relation to other health professionals
- Lack of participation in clinic updates and research with colleagues and others members of the team

Sociocultural, Religious, and Spiritual Issues:
- High level of distressing, unbearable pain and low expectations in unrelied oncological patients
- Difficulty of communication between rural population and palliative care centers in big cities because of large distances
- Barriers to access of palliative care teams because of economic problems in needy populations
- Family need to work as an obstacle to taking care of the patient at home
- Rural population’s beliefs about folkloric/chamanes medicine and use of traditional complementary therapies in symptom control more frequently than use of traditional medicine
- Religious and family obstacles about end-of-life decision-making
- Difficulties in management of spiritual suffering associated with chronic, advanced, and progressive disease by health professionals

Ethical Issues Influencing End-of-Life Care:
- Difficulties about end-of-life decision-making: terminal sedation vs. euthanasia, truth and bad news communication, silence conspiracy vs. patient autonomy, diagnosis and prognosis disclosure
- Inequality in the distribution of health resources
- Futility in the end-of-life ICUs in many hospitals
- Failure to address issues surrounding death and dying
- Lack of palliative care quality-of-life standards

Strengths

Government Policy:
- Some countries in the beginning of the development of palliative care national or regional policy
- Integration of the different health professions and scientific societies creating organization rules and standards, with government agreement

Availability of and Access to Opioids Analgesics:
- Availability of analgesic opioid but with restrictions to access for the whole population
- Opioid consumption increased over the last few years

Education:
- Some educational activities for health professionals before and after graduation but not systematic training.
- A few palliative care training opportunities for professionals together with experienced palliative care teams locally and abroad
- Nongovernmental organizations’ support of palliative care advanced-education programs
- Human resources of health care with specific training in palliative care, not many but goods.

The Palliative Care Team:
- An increase in palliative care teams with active assistance programs for adults and children, most of them in public hospitals
- Support of the initiatives and programs by international organizations, with the agreement of leaders
- Exchange of experiences and resources with other regional groups or countries
- No governments, local associations, or foundations that promote and practice palliative care
- Possibility to work in an interdisciplinary way in some cities and regions
- An increasing use of rules and symptom-control protocols
- There are associations of palliative care that coordinate scientific activities in most South American countries.

Sociocultural, Religious, and Spiritual Issues:
- Change of attitudes relating to palliative care in people and professionals: “cure” attitude vs. “care” attitude
- Family inclusion in care of the patient at home and in the hospital setting
- Increased family, friends’, or neighbors’ role in providing care to ease the process of adaptation
- Patient’s and families’ satisfaction with the palliative care team’s assistance at home
• Volunteers and social networks for providing resources locally
• Acceptance and approval of palliative care by different religions, with official recognition, especially by the Catholic church

Ethical Issues Influencing End-of-Life Care:
• There are more hospital ethical committees collaborating with palliative care teams regarding the difficulties in end-of-life decision-making.

Challenges of Palliative Care in South America

Government Policy:
• Integrate palliative care programs into national, provincial, municipal, and regionals health systems.
• Implement palliative care teams, services, or units in all countries according to individual needs.
• Establish rules, standards, handbooks, and team directories, by professional team leaders, according to international guidelines, with regional and cultural adaptations.
• Ensure governmental and nongovernmental institutions work together to identify communities’ palliative care needs and, by integrating resources, determine the most effective care delivery.
• Improve distribution of health resources.
• Detect and resolve obstacles blocking implementation of palliative care programs.
• Develop regional strategies and communication among South American countries, and request international support.

Availability of and Access to Opioid Analgesics:
• Include universal availability and allocation of recommended opioid analgesic with free access for the whole population.
• Enact laws that assure coverage of treatment for palliative care patients.
• Decrease the cost of the opioids.

Education:
• Distribute information about palliative care throughout the population.
• Determine attitudes regarding morphine prescription and myths and carry out popular education related to findings.
• Assure systematic palliative care training activities for health professionals both before and after graduation, with inclusion in the curriculum.
• Provide masters, specialized degree, and diploma levels in palliative care professionals’ education.

• Provide exchange of professionals with training in palliative care for education programs in developing countries.

The Palliative Care Team:
• Develop communication between government and institutions’ administrators to implement and consolidate palliative care programs, using community resources.
• Design own palliative care standards, professionals’ certification, and systematic services accreditation.
• Include palliative care in the early stages of patient assistance to improve care management and to provide services complementary with other medical specialties.
• Eliminate interprofessional communication barriers in the team.
• Include psychotherapists with training in palliative care team support to avoid burn-out situations.
• Develop a supportive group that includes volunteers and charitable funding to support palliative care teams.
• Create an operational network of palliative care providers among different cities, regions, and countries.
• Increase opportunities for researchers to work together.
• Create palliative care associations throughout South America.

The Nurse’s Role in the Palliative Care Team:
• Achieve standards of training in palliative care and relief of pain for all nursing levels.
• Include palliative care in schools’ and universities’ nursing curriculum.
• Create awareness of the nurse’s role in the interdisciplinary palliative care team and as change agent in the society.
• Increase the nurse’s participation in clinic update and research with colleagues and other members of the team.

Sociocultural, Religious, and Spiritual Issues:
• Adapt international models to the South American multicultural/sociopolitical environment, reality, and resources, and define each country’s own palliative care model.
• Respect culture values in different ethnic groups and be aware of the need for cross-cultural palliative care teams appropriate for aboriginal culture of South America.
• Establish volunteers and social networks to provide resources.
• Make communities aware of their rights to increase requests for palliative care’s efficient services.
• Develop palliative care in all places with own resources, even in poor countries and among marginalized communities.
• Emphasize the important role of the family in providing care in places with few palliative care human resources.

Ethical Issues Influencing End-of-Life Care:
• Provide widespread information to the population about end-of-life decision-making in relation to incurable diseases.
• Ensure greater participation of palliative care professionals in the discussion about euthanasia.
• Collaborate with authorities and legislators to advance knowledge about palliative care’s objectives and scopes.
• Institutions need to demand that health professionals assure ethical and quality palliative care for patients.
• People must demand respect for human rights and ethical basic principles from health professionals, including autonomy, beneficence, nonmaleficence, and justice.

Conclusions

Palliative care as a medical discipline began to grow throughout South America in the mid-1980s thanks to the pioneer initiatives of multiprofessional health teams, working with a holistic approach to promote the care of dying people. These first initiatives were supported by the enthusiasm of their leaders and were able to prosper with few available resources, both inside and outside of the hospital setting. At that time, institutional recognition was either partial or nonexistent. The teams were small and the job was hard; however, they have grown a lot and been an instrument of change in bettering citizens’ quality of life. Many difficulties still remain, and the need to provide skilled and compassionate care for seriously ill and dying patients is now being recognized as a major challenge in most South American countries.

In recent years, WHO has proposed providing more palliative care at the time of diagnosis for patients in developing countries. The reasons behind this are that by the time many patients get to the doctor, it is either too late in the course of their disease, the country/institution is unable to offer a curative therapy, or the patient is unable to access curative options. Therefore, they need a great deal more palliative care. It means that the allocation of resources in their countries and in their institutions should not be focused necessarily on diagnostic and curative oncological procedures and therapies, but rather, on issues such as adequate access to and availability of opioids and other medications.

The developing countries need technological and financial support to develop palliative care programs that cover the patients with advanced and progressive disease and family needs. International and nongovernmental organizations play an important role in this process and must offer assistance as much as possible. In a sense, WHO and PAHO can cause a stir in the development of new programs and in the consolidation of the existing ones.

Because of the great diversity of resources in South American health systems, there are many different methods that exist for providing palliative care. Integrating resources from public sectors and nongovernmental organizations can facilitate the implementation of programs, the promotion of palliative care services, and the provision of research and education opportunities. There are also scientific associations of palliative care in almost all countries.

In South America, there is evidence of growth in palliative care initiatives to improve availability of opioid analgesics for the treatment of cancer pain, as well as more educational opportunities for physicians, nurses, social workers, psychologists, and, at the community level, volunteers.

There is still a great need to develop national health policies that promote and implement palliative care as an effective way of assisting people suffering from advanced and terminal disease. The social and economic crises of South American countries is a good opportunity to encourage programs of great medical-social importance, verifiable cost-effectiveness, evident user satisfaction, and efficiency. High-quality palliative care programs meeting these criteria have been proven effective.

Such policies also must increase undergraduate and postgraduate education opportunities and research on palliative care topics, including ethics. There is also a need to promote home care as a low-cost option, making it an important resource for developing and poor countries. Active participation by the entire health care system, by members of community groups, and, most importantly, by patients and families, is needed.

Today, the majority of people in South American cities die in hospitals, and care must be provided in this setting. But it is also important not forget the Latin American tradition that identifies relatives as the main caregivers. This means active participation of families in care, even in the hospitals. When models of palliative care are being designed, one must also consider the diverse needs of a multicultural society.

Palliative care’s aim has been a model of care based on the concept of an interdisciplinary, multiprofessional team: nurses, physicians, social workers, psychologists, religious care providers, pharmacists, physio/occupational therapists, and volunteers. In South American countries, palliative care strongly highlights nurses’ roles, and they are beginning to be considered as important members of the team. However, we must also remember that the doctor’s role was traditionally hierarchical, and physicians maintained a paternalistic relationship with other team members—though this situation is beginning to change.

South American nurses are the front line in their respective teams, fighting against the difficulties in providing palliative
care. There has been much personal effort by each nurse to improve her or his own scientific knowledge and professional skills. However, in this region, there is still much to be done to allow dying people to live with dignity until the end of their lives. We, the South American nurses, have assumed this commitment.

A good death is as difficult to define as a good life in that the former is, or should be, an extension of the latter. What makes life enjoyable and worth living does not change when a person is dying. But while most of us are concerned with how to make our lives as good as possible, we rarely think about what might make our deaths good. We might consider the details of dying while reading serious fiction, however, we are unlikely to think of them in the context of our daily experience. But to paraphrase an old saw, there is nothing like the prospect of death to focus a person’s attention. The dying want their deaths and what remains of their lives to be as good as possible. They count on palliative care nurses to do as much as possible to ensure this goodness. Of course, there may come a time for any patient when death will seem preferable to life. For example, an 87-year-old man dying of lung cancer, who was an informant in our study of cancer patients in hospice, stated: “I’m going downhill now and I don’t like it. It just gets harder to breathe. I can see that eventually I’ll be far enough down that hill that it will be better to be at the bottom and dead than still sliding down.” The goal of palliative care is to ensure that this desire for the bottom of the hill is not inevitable even though finally reaching that bottom may be.

The goal of palliative care nurses is to attend to the symptoms that are part of the disease from which their clients are dying: pain, fatigue, nausea, constipation, depression and/or anxiety, dry mouth, and so on. The ideal is to work quickly and carefully, attending the specifics of each problem as soon as they arise. Clinical practice with suffering and dying people takes place in the immediate present. Often there is little time to step back and look at the situation from a broader and longer temporal perspective. The desire for this broader view is probably chief among the impetuses that lead us into doing research.

In our research, we have the luxury of stepping back from the immediate demands of alleviating symptoms into a more distanced position of participant-observer, if such a thing is possible. In this role, we watch and interview and consider the
dying of patients from as many points of view as possible: patient, family, and clinicians, as well as our own. The result of these observations is a text, the written account of what we have seen and been told. These texts naturally take the form of narratives or stories of dying. Our approach is in keeping with the narrative turn of recent social science, which is predicated on the belief that narratives of illness and other forms of suffering provide access to the private and cultural life-worlds of individuals.8–11 This turn or trend toward narrative has been put to good use in understanding the experience of death, dying, and bereavement.2

Our hope is that our contribution of stories and their analysis will further the goals of theory and research and in so doing improve practice. However, dying is as complex and ambiguous and as relatively inexplicable as living; therefore these narratives often raise more questions than can be answered given the current state of knowledge about death and dying. But our narratives may afford their readers an opportunity to step back and view the phenomenon from a perspective that is longer in time, broader in framework, and deeper in reflection than might otherwise be available. In this regard, we present the narrative below, James’s story,* which is one of more than a hundred we have collected in our research on suffering and making meaning of suffering at the end of life. This narrative, which takes the point of view of a husband caring for his dying wife, is typical of many of our stories in terms of themes, timing and events. However, the specific details of an individual’s experience are unique as lived.2

CASE STUDY

James’s Story

December 7

James, a man in his early 80s, is caring for his wife, Marti, who is dying of a neurological disease of which he can never remember the name. When I first meet him, Marti has been in the hospice program for 3 or 4 months. She is almost completely paralyzed. Each morning James bathes her in bed, transfers her to a wheelchair, and brings her to the kitchen. He cooks breakfast and feeds her, then turns her chair so she can look out the window or watch television. She is unable to speak, but he has learned to interpret the sounds she can make and the small slow gestures she can make with her hands. But mostly she communicates with her eyes and her smile, both of which are bright and expressive. James says he appreciates having the hospice aide come and bathe her twice a week, because then he can make the 27-mile trip to the nearest supermarket for groceries—they live deep in the country.

More than once, doctors have suggested that James put Marti in a nursing home, but he refuses. “So impersonal, and if she go in a nursing home, well, we gonna lose everything anyway, 'cause nursing home’s still gonna take the house—they take everything. It just wipe out the little saving you got, just like that.”

James is proud of his independence. “I always made it on my own. Lot of people tell me, they say what a wonderful job I do with her . . . but you see, I just try to do the right thing. Now, when I came up, it was during the Depression, and people didn’t have nothin’, and my daddy and them had that land, but they ain’t had no money. We had plenty of food, but as far as money and clothes, you got what you could get. And people didn’t have less or no more than you had, so couldn’t nobody help nobody . . . but just as soon as I could, I got me a job and went to work and helped taking care of the others. I’ve been takin’ care of family before I got married.”

James and Marti were part of the diaspora of African Americans from the south to north that started in the 1930s and continued through the 1950s. He and Marti married in rural Virginia—to which they returned when Marti became ill—but moved north while they were both young. She went to Philadelphia and he to Brooklyn. They agreed that the first one to find good prospects would send for the other. In a few months, Marti lied and said she had found him a good job. She missed him too much. He was not angry when he arrived and there was no job. Things worked out in Philadelphia anyway.

January 3

James says Marti has been doing better since Christmas. She has her good days and bad, but lately she has been a little stronger. The changes are subtle, he says, but because he is here and sees her every day, he notices them. She raises her arms now to help with dressing and is able to bring a cup to her mouth more often.

He tells me about the work he has to do around the house. He purees all of Marti’s food now. He had never been a cook but has learned recently. It is also clear that he keeps an immaculate house. He said he had always worked outside the house and had to learn housekeeping from scratch. But cleaning “came natural” to him. He wants a spotless house. It is also very important to him that Marti is clean and has her hair combed every morning.

February 15

Marti is a little weaker now. A few weeks ago, she was able to take a step or two with James’s help, but now she will not try. She can no longer swallow her medications, and James is applying transdermal patches. As I watch him feed her a pureed lunch, I cannot see much change in her condition.

In Philadelphia in the 1960s and 1970s, James and Marti organized a floating poker game with a group of friends. The game would move from house to house two or three times a week, and locals and neighbors would be invited. Whoever was

*Names have been changed to ensure confidentiality. The use of first names reflects the relationships established and how the participants wanted to be addressed and written about. The appropriate university committee for the protection of human subjects approved the procedures of the research study from which this narrative evolved.
hosting the game would skim 10% from the pots. Soon, James was making wine in his basement and selling it by the glass at the games. Marti didn’t drink, but she was a great poker player. She developed a reputation, and soon people who knew her skills would not sit at the same table with her. As they grew older, James became more religious. He stopped drinking and playing cards, joined the church, and even became a deacon. Marti refused to join the church and was organizing poker games in the country even from her wheelchair. James said he was worried about her soul, but when he said this in front of her, she would grin and her eyes would twinkle.

James explains how Marti came to be in the hospice program. “We done spent thousands and thousands of dollars [on Marti’s medical care]. But now, we certainly was blessed when this doctor one day said, ’James, I’m gonna tell you the truth. There’s no man that I know of that has been trying to do more for their wife than you. You are two nice people. But if things keep on going like it going, I don’t know . . . there’s such a thing as nursing homes, you know that, don’t you?’

But I said I seen too much going on in ’em. Nursing home, that gonna be the last result. So, then, he said, ’Yeah, I know what you saying. But, if there ever was two people need any help, it’s y’all, ’cause you ain’t eligible for Medicaid. So there’s a company I’m gonna try to contact and see what I can do for y’all.’ That’s how we got in the hospice.”

James says his age makes it difficult for him to do all the work that needs to be done in the house and around his two acres. But he does some things he believes keep him healthy. He keeps strands of copper wire, and when he has cramps, wraps that area of his body with the wire. At night, he drinks vinegar and takes a quinine pill to help him sleep and stay well. He prays for Marti to be healed, but that does not seem to him to be working. But his prayers that he stay well and strong do seem to be working. He believes his “powers” are strong enough for himself but not for her.

His friends admire how he is helping his wife and refusing to put her in a nursing home, and they are helping him financially. He makes money by fattening calves on his two acres over the summer. A friend gives him deep discounts on the calves and on the hay he needs to feed them before the grass comes in. Another friend has told him what he must do to raise the cattle so they can be sold to a kosher butcher at a premium price. Yet another friend has told him he will fix his car for the price of the parts. Even the local itinerant barber who serves the black community will come to his house and cut his hair at discount.

James and Marti have always been in the flea market trade. They used to buy broken bicycles at the dump, fix and paint them, then sell them at market. Marti is too sick to go now, and James misses the money and the fun. He says in private that when Marti “passes” he will take all her clothes and sell them at the flea market, because that is what she would want.

March 2

Marti is doing about the same, but their granddaughter-in-law, the wife of a grandson they raised because their oldest son had deserted his family, has just died of cancer. James’s brother is dying of liver cancer, and James is trying to arrange a trip to New Jersey to see him one last time. His challenge is to find somebody he can trust to stay with Marti, and that someone has to be willing to do it for room and board.

March 25

Marti doesn’t look as well today. James says she is having a down day. She sleeps most of the time I am there, opening her eyes occasionally, looking around, trying to wipe her eyes with a napkin, then sleeping some more. James is going to call hospice and have them come out and take a look at her.

This week has been awful for them. Their next-door neighbors to the south were Marti’s older sister (near 90) and her son. In the middle of the night, James was awakened by heavy traffic on their dirt road and looked out to see fire trucks and his sister-in-law’s house on fire. The place burned to the ground, and both she and her son died. Marti was not told immediately. James called hospice and asked someone to come out because he worried about how she might react. So the day after the fire, the hospice nurse and social worker came out. James says that Marti did not seem to react: “She didn’t make no expression, you know, she didn’t output no sorrowness or no surprise or no nothing. I was afraid to take a chance on this. This was her sister. But she still didn’t, so then we discover it must be rough inside. But something wrong with her output.” He decided her disease was preventing her from expressing how she felt inside.

I ask James how he is handling all these deaths. He says, “I don’t care how often death come around, he’s a stranger.”

April 12

Marti seems unchanged. She recovered a little from being withdrawn but not completely. As I am visiting, the hospice nurse is visiting as well. As she leaves, she says to Marti, “See you next week.” Marti shakes her head, no. The nurse says, “I hope to see you at least.” Out of James’s hearing, the nurse tells me that patients know when their death is coming and she does not expect to see Marti next week.

A few years ago, when Marti was fairly well, James was teasing her about being a month younger than she is. James says Martha told him, “Well, when the both of us get old, and I’ve died of old age, and you come to my funeral all dressed up in your finest clothes, I wouldn’t bother going home and changing because you will be joining me soon.”

June 1

Marti did not die that week, she died on the 24th of May, 6 weeks later. James tells me the whole story of her decline. Six years ago she gave up walking on her own. For another 2 years she could feed herself. But for the last 4 years, he has been feeding her. Each step down was very gradual.

In retrospect, James believes Marti started to die the week her sister died in the fire. “Laurie [the hospice nurse] was away on her vacation when Marti passed. She wasn’t doing good, just wouldn’t half eat. These worldly things she...
wouldn’t pay no attention to. You tell her something like when the house burned down . . . she didn’t do nothing. She just held her chin. I said, you understand what I’m saying? She said, ‘Uh huh,’ shaking her head yeah.”

At the time, James accepted the nurse’s interpretation that Marti could not express herself but was feeling the pain inside. Later in the day when he moved Marti in her wheelchair out to the kitchen, he did not put her in her usual spot by the window because the burning embers of her sister’s house were the center of the burning. But Marti insisted. She stared out the window but did not seem moved. James says, “Something tell me she was giving up. I just believe as time goes on, you start to giving up the worldly things, when you’re coming near the time to go. Because you be giving up the world, gradually giving up all the worldly things.”

Marti had responded with no emotion when James told her about the death of her granddaughter-in-law, and even when he had shown her a picture of her new great granddaughter. She smiled briefly and went back to staring out the window.

One day Marti refused to eat. She would turn away from the spoon James offered. When he insisted, she would take the food in her mouth and spit it back out when he turned his back. James called Laurie and asked her to come out. Two days later, Laurie came and examined Marti and said it was close to the end and presented James with some choices. James says, “Laurie told me maybe we can have IV come in. You have a nurse come in here and give her fluid and do this and do that, right here at home, and we don’t have to put her in the hospital or nursing home. I said, Laurie, I know how you feel about these places. But sometime you come to a time you have to do what you got to do. I’m mighty afraid this is the time for the hospital. I’m not talking about the nursing home. I am just talking about hospital because it’s round the clock. They are with you 24 hours.”

Laurie calls Marti’s doctor and arranges to have her admitted, then calls the ambulance. James busies himself with packing her nightgowns and medications. He says, “Laurie comes, tapping me on the shoulder. She says, ‘You know what, James?’ I said, What? ‘Marti decided that she don’t want to go to the hospital.’ I said, Oh, no. Are you sure you understood what she said? Because you are not with her every day, maybe you misunderstood. She said, ‘No, I’m sure.’ I said, ‘Wait a minute, let me go back in there.’ The ambulance people is all at the bed, you know, for to take her out and put her on the stretcher. Before I could get in there, Laurie said, ‘James, Marti’s passing now . . . she’s on her way out.’ I said, ‘Now you got to be kidding.’ Boy, I goes in there, I put my hand on top of her head, I just pat on it, you know, then that was it.”

Discussion

Narratives are not reality. What we actually experience is more complex and nuanced than any story about experience can hope to capture. However, listening to the stories of others may be as close as we will ever come to being able to understand experiences not our own. In fact, nursing is developing a tradition of using narratives to understand illness. Nurses began to write about this approach starting in the early 1990s.12–15 Narratives provide to nurses who are trying to understand and to treat suffering at the end of life an opportunity to see palliative care in as much of its complexity as possible, the nonlinear, nonrational, and contradictory complexity of experience as it appears in narrative. The story of James and Marti can stand alone in portraying that complexity, but a few comments might also be helpful. James and Marti can be seen as experiencing this death on a number of different levels, as a political/economic event, as a spiritual event, and as an aesthetic event.

Political/Economic Aspects of Marti’s Death

For James, the politics of his situation are manifest at the most basic level and the highest level. James and Marti seemed to have always participated in an underground economy. From legitimate participation in flea markets to illegal wine and gambling ventures, they found a way to supplement their incomes (while having fun). Now, when James needs help, his friends are generous. He receives deep discounts and free labor. The itinerant barber probably has no business license and no formal training and makes his living below the view of official bureaucracies, but he is no swindler and is willing to help a friend in need.

James and Marti have Social Security and own a home, and thus are not eligible for Medicaid. James is savvy enough to realize that he would have to spend enough of his assets to become poor before he could receive more government help. The idea of spending his money on a nursing home would be an anathema to James’s sense of financial responsibility. He would be spending too much for a service he does not believe provides quality.

Hospice is the kind of service James can appreciate. He increases his benefits in terms of having a team to help with symptom control and in medication costs. As with most caregivers, his own economic contribution to Marti’s care has been both considerable and invisible to any official agency. Research has also confirmed James’s situation in that the burden of caregiving was always very high and increased tremendously in the last stages of Marti’s life, which is typical of many families.16–19

His recounting of Marti’s doctor’s referral to hospice makes it sound as though it was a “social” referral. James and Marti needed the help. They were good, hardworking people. The doctor saw them as deserving, and thus referred them to hospice. Of course, this is not the way it is supposed to happen. The standards should be objective and not based on how much a physician likes a family. And of course, this is James’s story of what happened and does not necessarily actually reflect what the doctor was thinking, what he did in terms of the paperwork, or even what he actually said to James. We all make sense of conversations based on what we want to hear and believe. Marti was in the hospice program for a little under a year with a neurodegenerative disease, the progression of which is very difficult to predict.
That nursing homes are seen as not good options for the dying elderly, and that an elderly man believes he must spend himself into poverty to receive help keeping his wife in a nursing home are failures of the system. Or at least they are failures if one believes that having options for good care at the end of life is something we owe every citizen and not just those who can pay. James wants Marti to die in the hospital, where, in his experience, she will receive excellent round-the-clock care. He does not question the right for Marti to be there. Hospitals are for the sick, and Marti is dying, which is as sick as one can be. The hospice nurse who comes to make the transfer offers James other options, such as increased home therapy. Her motives, we would guess, are first to offer James as wide a range of options as possible. However, as a hospice nurse, she must also keep in mind that hospitalization is the most expensive care Marti can receive and hospice will have to pay for it. Comfortable deaths at home are prized by hospices, who are rewarded for them, but a well-attended death in a hospital is prized by James.

The lesson for palliative care nurses in this part of James's story is one we already know but need to keep ourselves reminded of. There are none better than us, palliative care nurses, at knowing when and how the system does not work. We have an obligation to be politically active on behalf of the people whose lives are so deeply affected by this system of rules and regulations. Families suffering the loss of a loved one are perhaps more vulnerable than at any other time and need professionals advocating for them when they are struggling to care for themselves and their family member.

Spiritual Aspects of Marti's Death

Nurses and other clinicians have long recognized that dying is a spiritual event for most people. James is a religious man, but, interestingly, he does not use the occasion of his wife's illness to think about what is arguably the central question in all religions, why must human beings suffer? Or maybe because he is religious, he does not need to consider this question. He does, however, test the power of prayer with Marti’s illness. When he prays for his own health, his prayers are effective, but when he prays for Marti’s health, these prayers do not work. He says his powers are limited. It is as though the power of prayer lies within James and not in God. He does not entertain the idea that his prayer for Marti to be healed is not answered because it is not God’s will that she continue to live. He does not seem to believe that the power of prayer lies in the prayer itself or in the goal of the prayer, but lies in the one who is praying. This is both an assumed position of great power and of great vulnerability. If he has the power to keep himself well, what is wrong with him that he cannot heal his wife? Is his faith not as strong as the disease it must overcome? James does not seem to be dismayed by his lack of power; he treats it as a fact he must accept.

After James told us that Marti seemed to be losing interest in life, we began to wonder if she was depressed. Marti showed signs of anhedonia and dysthymia. She was more withdrawn and less communicative. Our conviction is that depression is a disease and should be treated aggressively when it is discovered, both because the disease can cause damage to bodily organs (the changes in the brain caused by depression are well documented) and because it causes unnecessary suffering. Because someone is nearing the end of life does not mean that he or she should not be treated for depression—just as we would not let a diabetic’s blood sugar wildly fluctuate just because he or she is in a hospice program. But treating Marti’s depression, if indeed she was depressed, could have spiritual ramifications. James believes that Marti was giving up the things of this life in order to move on to the next life. In his mind, she was starting a spiritual journey, not becoming depressed. If Marti were treated with an antidepressant and became more involved in life, would James have appreciated this backward step in her spiritual journey? Of course, Marti might not have seen it as a spiritual journey and may have appreciated something that would lighten her mood. Sometimes what is spiritual and what is medical are confused and confusing. Nurses’ responsibilities are not easily defined or carried out in this area, but they cannot be denied.

Aesthetic Aspects of Marti’s Death

Art is the conscious molding of the raw experiences of life into something that is important, meaningful, and has the potential of enlightening us in some way. Ceremonies such as weddings, graduations, baptisms, and funerals can be, if done with originality and care, art forms. These rituals are culturally constructed to make them beautiful and give them all the meaning and portent that beauty implies. To some degree, births and deaths can fall into this category. But one could argue that art implies an artist, someone controlling and creating the experience for an audience, and what is possible to be controlled often seems very little in birth and death. However, there are parts of death and birth over which nurses do have control, and we contend that nurses can and will be judged on the aesthetic qualities of these events. An older person dying of cancer being coded in a busy, noisy emergency department may well be remembered by the family as an ugly death, as might the sudden exsanguination of a patient who has no platelets secondary to a terminal disease. On the other hand, most of us who have worked in palliative care have heard family members tell us, weeks after an expected death in a quiet room with family all in attendance, that the death was beautiful.

On its most basic level, the qualities used to make aesthetic judgments are boundaries, rhythm, and clarity [these are adapted from Aquinas]. In terms of boundaries, artistic or aesthetic narratives have beginnings, middles, and endings. While it is true that some of the boundaries of James’s story are established by his telling and our rendition of it, much of the experience fits well into a self-contained story. The story of Marti’s dying starts rather vaguely. Marti has been sick for a long time and has progressively become more debilitated. James never says that her disease is incurable and never says that Marti is dying, but the fact seems to be a given. The story can be said to have started when Marti is referred to hospice,
even though James does not acknowledge that the hospice program is for the dying, he was surely told that it was. As with most stories we tell about ourselves, the beginning is not as clearly delineated as the ending.

As the narrative progresses, James does not use the dominant metaphor, the one we heard in most of the interviews, that of a struggle or a war. We often heard that a patient and family were fighting against the disease and trying to overcome it. Often the caregiver and the patient were proud of how hard they struggled against death and did not give up. For James, the metaphor was one of a journey or a passage rather than a fight. He talks about Marti’s “passing” and “moving on.” When he does use the term “giving up,” he is referring to her relinquishing one world for another, not refusing to fight. For James, the narrative of Marti’s death was a long, slowly played-out journey.

James has some fairly strong ideas about the elements that should be in the middle of the narrative. The narrative should not be about the slow decline of their financial status and their ability to be independent. The story should have James and Marti as the major characters. James does not believe that other caregivers should play a major role, although he appreciates all the help he receives. Finally, he wants the ending of the narrative to play out at home and not in a nursing home. Nursing homes are too ugly—uncaring, impersonal, and expensive—for Marti. But the final act of the story should take place in the hospital. James holds that narratives about expected deaths should end in the hospital where people are ready to deal with such things. The fact that Marti appeared to decide otherwise was, however, not a great disappointment to him. If someone else besides Marti had decided she should die at home or in a nursing home, James would probably not have been so contented.

This “choice” by Marti leads to the second criteria for an aesthetic death, rhythm. Marti dies when she should in James’ narrative, much the opposite of the Colonel in Gabriel Garcia Marquez’s great novel, One Hundred Years of Solitude, who, when asked as an old man why he is still alive, says “A man dies when he can, not when he should.” Marti moves slowly toward death, and her death is the last in a series that, for James, are precursors and rehearsals. As in a well-wrought play, Marti, as the central figure, watches others die before her, each one seemingly making her own death a little more inevitable. The final node in this narrative rhythm is the death of Marti’s sister. We, of course, do not see the rhythm of the narrative from Marti’s point of view, but James understands his sister-in-law’s death as a precursor. Whether her sister’s death is the occasion for Marti to move toward the other world or merely an opportunity for her to demonstrate that she has already started that movement, is not clear in James’s story. However, the rhythm of the narrative is demonstrable in terms of the Marti’s slow decline and the spacing of the deaths leading up to her own climatic one.

The third aesthetic criterion is clarity, our translation of the Aquinas’ claritas. By this we mean a sense that things generally happened in a meaningful way. That is, Marti’s death was not random or arbitrary or contingent (although a contingent death might fit well with a postmodern aesthetic). Not that Marti was supposed to die. Her death was tragic and sad. But there was a sense of the inevitable about it. Marti did not die because of something done or left undone by James or anyone else. She did not die from a medical mistake, or because James did not call the ambulance in time. An aesthetically satisfying story does not leave the listener with anger or guilt. Instead, one is left with a sense of clarity. That is, the sadness is deep and profound, but the reasons are clear and not confused with regrets about what was done or left undone.

Palliative care is, to a great degree, about helping people create a narrative about a death that has as many aesthetic qualities as possible. James directed (in the sense that one directs a play or movie) Marti’s dying for the most part. But at the very end, the hospice nurse stepped in and, while she did not change anything that happened, she changed the narrative by offering James a way of looking at the event. The nurse interpreted the narrative in such a way that gave Marti the power to decide her own time and manner of dying. The nurse orchestrated, to some degree, the meaning of the event. Whether we as palliative care nurses want the responsibility of orchestrating a death or not, we often have it. We have to learn the rhythm of the narrative to know when it is time for the dying person to stay home and when it is time to call the ambulance.

What is aesthetically satisfying to one family may not be to another. For many families, the narrative should end at home and not in the hospital, where the dying person would be surrounded by strangers. James wanted Marti to die in the hospital where she would receive around-the-clock expert care. That was the ending he intended. Should James have been able to dictate this part of the narrative? Certainly. But how much should he be able to dictate? What if Marti had been in excruciating pain at the end of life and James had wanted her to receive a morphine dosage aimed at not only stopping the pain but at helping her pass to the next world? Luckily, Marti did not die in pain, and we are not suggesting that medical treatments, such as the titration of morphine, be dictated by the aesthetic sensibilities of the family alone. We are arguing that nurses and physicians must realize that this sense of aesthetics should be a part of the considerations.

Summary

In this presentation of James’s story and our discussion of it, we have carefully avoided defining a good death or predicting or prescribing how to achieve one. The complexity of the experience prevents our doing so. Offering prescriptions would be denying the differences that make stories meaningful. What we mean by this is that there are no general cases; there are no theoretical lives; living is never done in the abstract. This seems obvious, but it may sometimes be lost in the science of our practice. Usually we base our interventions on what works most of the time for most people. This is the essence of science-based nursing practice. We do things to help our patients based on a high probability that it will work, and that probability is based on an abstraction. It is based on looking at many cases and generalizing about what usually happens. Necessarily, the
specifics of individuals must be lost in the process of making general statements.

Thus, there is a tension between the goals of science, producing abstract general knowledge that can be acted upon with some confidence of success, and the notion that narratives are unique and cannot be prescribed. Our goal has been to bridge this gap and reduce the tension through the use of narratives. A narrative approach to understanding palliative care can rescue the individual particularities of life from being lost in our practice and, at the same time, offer some abstractions to guide clinicians, such as the elements of aesthetics, and an attention to political and economic and spiritual issues. Listening to James and Marti’s story—their move to the urban north, the floating poker games and bootlegging, their cows and flea markets and network of friends—makes it impossible to see them as anything but a real couple with a complex life that is uniquely theirs. Recognizing this “suchness” of their lives cannot help but make us care for them in a different way.
